**Children.** 0.01 mg/kg over 15 sec, repeated after waiting 45 sec if response is inadequate and then repeated every 1 min, if needed, up to 4 additional doses. *Maximum:* 5 doses total, not exceeding accumulative dosage of 0.05 mg/kg or 1 mg, whichever is lower.

- *To reverse benzodiazepine toxicity or suspected overdose*

## I.V. INJECTION

**Adults.** 0.2 mg given over 30 sec followed by 0.3 mg after waiting 30 sec if response is inadequate and then 0.5 mg given over 30 sec at 1-min intervals, if needed, to maximum dose. If sedation recurs, regimen is repeated every 20 min. *Maximum:* Cycle repeated every 20 min 3 times for a total of 3 mg in 1-hr period.

Route	Onset	Peak	Duration
I.V.	1-2 min	6-10 min	Variable

## Mechanism of Action

Antagonizes CNS effects of benzodiazepines by competing for their binding sites.

# Contraindications

Evidence of tricyclic antidepressant overdose; hypersensitivity to flumazenil, benzodiazepines, or their components; use of benzodiazepine to control intracranial pressure, status epilepticus, or a potentially life-threatening condition

# Interactions

## DRUGS

*benzodiazepines*: Benzodiazepine withdrawal symptoms, including seizures

*nonbenzodiazepine agonists*: Loss of effectiveness of these drugs

*tetracyclic or tricyclic antidepressant overdose*: High risk of seizures

# Adverse Reactions

**CNS**: Agitation, anxiety, ataxia, confusion, dizziness, drowsiness, emotional lability, fatigue, headache, hypoesthesia, insomnia, paresthesia, resedation, **seizures**, tremor, vertigo

**CV**: Hot flashes, hypertension, palpitations

**EENT**: Blurred vision, diplopia, dry mouth

**GI**: Nausea, vomiting

**RESP**: Dyspnea, hyperventilation, **hypoventilation**

**SKIN**: Diaphoresis, flushing, rash

**Other**: Injection-site pain and thrombophlebitis

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Not recommended for use during labor and delivery.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use flumazenil cautiously in patients with cardiac disease. Assess for increased anxiety or stress from benzodiazepine withdrawal because patient's blood pressure may rise.
- Give flumazenil undiluted or diluted in a syringe with D<sub>5</sub>W, lactated Ringer's solution, or normal saline solution. Administer over 15 to 30 seconds directly into tubing of a free-flowing compatible I.V. solution. Use a large vein, if possible, to minimize pain at site. Avoid extravasation because drug may irritate tissue.
- Be aware that drug may cause signs of benzodiazepine withdrawal in drug-dependent patient. Also, abrupt awakening from benzodiazepine overdose can cause agitation, dysphoria, and increased adverse reactions.
- Be aware that benzodiazepine reversal may cause an anxiety or a panic attack for patient with a history of these episodes. Expect to adjust dosage carefully.
- Monitor patient for signs of hypoventilation or resedation for at least 2 hours after giving flumazenil because drug has a short half-life. Be aware

that patient shouldn't be discharged until the risk of resedation has resolved.

## PATIENT TEACHING

- Caution patient to avoid alcohol and OTC drugs for 10 to 24 hours after receiving drug.
- Advise patient to avoid hazardous activities for 18 to 24 hours after discharge.
- Inform patient and family that agitation, emotional lability, fear, and panic attack (if patient has a history of them) may occur. Tell them to seek medical care if patient has depression, flushing, hyperventilation, insomnia, palpitations, tremor, or trouble breathing.
- Provide written instructions or instructions to caregiver even if patient is alert, because drug doesn't always reverse postprocedure amnesia.

## fluoxetine hydrochloride

**Prozac, Sarafem**

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antidepressant

## Indications and Dosages

- *To treat acute depression; to provide maintenance therapy for depression*

**CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)**

**Adults.** *Initial:* 20 mg daily in the morning. Dosage increased every 4 to 8 wk as needed. Dosage greater than 20 mg daily given once daily in the morning or twice daily morning and noon. *Maximum:* 80 mg daily.

**Children ages 8 and older.** *Initial:* 10 mg daily. Increased after 1 wk to 20 mg daily.

- *To treat acute obsessive-compulsive disorder (OCD); to provide maintenance therapy for OCD*

### **CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)**

**Adults.** *Initial:* 20 mg daily in the morning. Dosage increased every 4 to 8 wk as needed. Dosage greater than 20 mg daily given once daily in morning or twice daily morning and noon. *Maximum:* 80 mg daily.

**Children ages 7 and older.** *Initial:* 10 mg daily. Dosage increased after 2 wk to 20 mg daily. Subsequent dosage increased, as needed, at intervals of at least several wk. *Maintenance:* 20 to 60 mg daily.

- *To treat moderate to severe bulimia nervosa; to provide maintenance therapy for bulimia nervosa*

### **CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)**

**Adults.** 60 mg daily in the morning. Alternatively, dosage titrated up to 60 mg daily over several days.

- *To treat acute panic disorder with or without agoraphobia*

### **CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)**

**Adults.** *Initial:* 10 mg daily. Dosage increased in 1 wk to 20 mg daily, as needed. Dosage further increased after several wk, as needed.

*Maximum:* 60 mg daily.

- *As adjunct to treat acute depressive episodes associated with bipolar I disorder*

## **CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)**

**Adults.** *Initial:* 20 mg given with 5 mg olanzapine once daily in the evening. Dosage adjusted, as needed. *Usual:* 20 to 50 mg with 5 to 12.5 mg olanzapine.

**Children age 10 and older.** *Initial:* 20 mg given with 2.5 mg olanzapine once daily in the evening. Dosage adjusted, as needed.

- *As adjunct to treat resistant depression*

## **CAPSULES, ORAL SOLUTION, TABLETS (PROZAC)**

**Adults.** *Initial:* 20 mg with 5 mg olanzapine. Dosage adjusted, as needed, *Usual:* 20 to 50 mg with 5 to 20 mg olanzapine.

***DOSAGE ADJUSTMENT*** For all indications with Prozac, dose or frequency reduced for adult patients with concurrent illness or hepatic impairment, those who take multiple medications, and for elderly patients. For lower-weight children taking drug for OCD, dosage increased above 10 mg daily only if clinical improvement remains insufficient after several weeks. Maintenance dosage for such children should not exceed 30 mg daily. For lower weight children taking drug for depression, dosage increased to 20 mg daily only if improvement insufficient after several weeks.

- *To treat premenstrual dysmorphic disorder*

## **TABLETS (SARAFEM)**

**Adults.** 20 mg daily given continuously (every day of the menstrual cycle) or intermittently (starting daily dose 14 days prior to the anticipated onset of menstruation through the first full day of menses and repeated with each new

cycle). Dosage increased as needed. *Maximum:* 80 mg daily.

**DOSAGE ADJUSTMENT** Dose or frequency reduced for patients with concurrent illness or hepatic impairment, or those who take multiple medications.

Route	Onset	Peak	Duration
P.O.*	1–6 wk <sup>†</sup>	Unknown	Unknown

\* Capsules, oral solution, and tablets.

† For depression and bulimia; 5 wk for obsessive-compulsive disorder.

## Mechanism of Action

Selectively inhibits reuptake of the neurotransmitter serotonin by CNS neurons and increases the amount of serotonin available in nerve synapses. An elevated serotonin level may result in elevated mood and, consequently, reduce depression, lessen obsessive-compulsive behavior, and diminish panic symptoms, as well as relieve premenstrual dysmorphic discomfort.

## Contraindications

Concurrent therapy with pimozide or thioridazine; hypersensitivity to fluoxetine, other selective serotonin reuptake inhibitors or their components; use within 14 days of MAO inhibitor therapy, including linezolid or intravenous methylene blue.

## Interactions

### DRUGS

*alprazolam, diazepam*: Possibly prolonged half-life of these drugs

*anticonvulsants*: Increased anticonvulsant levels with potential for toxicity

*aspirin, NSAIDs, warfarin*: Increased anticoagulant activity and risk of bleeding

*benzodiazepines, CNS depressants*: Increased CNS effect and development of adverse effects

*CYP2D6-metabolized drugs, such as antiarrhythmics (especially flecainide, propafenone), antidepressants (tricyclics), antipsychotics (phenothiazines and most atypicals), thioridazine, and vinblastine*: Increased plasma levels of these drugs and increased risk of serious adverse reactions

*buspirone, fentanyl, intravenous methylene blue, linezolid, serotonergics (such as amphetamines and other psychostimulants, antidepressants, and dopamine agonists), St. John's wort, tramadol, tricyclic antidepressants, triptans, tryptophan*: Increased risk of serotonin syndrome

*highly protein-bound drugs*: Possibly increased risk of elevated plasma levels of drugs increasing risk of adverse effects

*lithium*: Decreased or increased lithium levels; potential for serotonergic effects

*MAO inhibitors*: Possibly severe and life-threatening adverse effects; increased risk of serotonin syndrome

*olanzapine*: Increased blood olanzapine levels with decreased clearance resulting in possible increased risk for adverse reactions

*phenytoin*: Increased blood phenytoin level and risk of toxicity

*pimozide, thioridazine, or other drugs that may prolong QT interval*: Increased blood levels of these drugs; possibly increased risk of prolonged QT interval

# Adverse Reactions

**CNS:** Akathisia, anxiety, ataxia, balance disorder, chills, depersonalization, dream disturbances, drowsiness, emotional lability, euphoria, fatigue, fever, headache, hypertonia, hypomania, insomnia, mania, myoclonus, nervousness, **neuroleptic malignant syndrome**, paranoid reaction, restlessness, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**, tremor, vertigo, weakness, yawning

**CV:** **Arrhythmias**, **hypotension**, palpitations, **prolonged QT interval**, **torsades de pointes**, **ventricular arrhythmias**

**EENT:** Abnormal vision, angle-closure glaucoma, dry mouth, mydriasis, pharyngitis, sinusitis, taste perversion, teeth grinding

**ENDO:** Galactorrhea, gynecomastia, **hypoglycemia**, syndrome of inappropriate antidiuretic hormone secretion (SIADH)

**GI:** Anorexia, diarrhea, dysphagia, gastritis, gastroenteritis, indigestion, **melena**, nausea, stomach ulcer

**GU:** Decreased or increased libido, dysuria, ejaculation disorders, gynecological bleeding, impotence, micturition disorder

**HEME:** **Altered platelet function**, **unusual bleeding**

**MS:** Arthralgia, myalgia

**RESP:** Dyspnea

**SKIN:** Alopecia, diaphoresis, ecchymosis, pruritus, rash, urticaria

**Other:** Flu-like symptoms, **hyponatremia**, weight loss

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm if administered during the third trimester.
- Neonates exposed to drug during the third trimester may develop serious complications after birth requiring prolonged hospitalization, respiratory support, and tube feeding.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

# Nursing Considerations

- Use fluoxetine cautiously in patients with a history of seizures and in children, because of potential for adverse effects.
- Use fluoxetine cautiously in patients with congenital long QT syndrome, previous history of QT prolongation, or family history of long QT syndrome or sudden cardiac death. In addition, use caution in presence of other conditions that increase risk of QT prolongation and ventricular arrhythmia, such as concurrent drug therapy with drugs known to prolong the QT interval, hypokalemia, hypomagnesemia, recent MI, significant arrhythmias, uncompensated heart failure and conditions that predispose patient to increased fluoxetine exposure, such as hepatic impairment or concurrent use of drugs known to increase blood fluoxetine levels such as CYP2D6 inhibitors, CYP2D6 poor metabolizer status, or use of other highly protein-bound drugs. Obtain an ECG recording, as ordered, before fluoxetine begins in these patients and periodically throughout therapy. Expect fluoxetine to be discontinued if the QT interval becomes prolonged or patient develops a ventricular arrhythmia.

**WARNING** Avoid giving fluoxetine within 14 days of an MAO inhibitor or starting MAO inhibitor therapy within 5 weeks of discontinuing fluoxetine.

- Know that patients with depression should be screened for bipolar disorder before fluoxetine therapy is started, because treating depression alone in these patients may precipitate a manic or mixed episode.
- Monitor patient for depression (especially children, adolescents, and young adults) and watch closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during those times.
- Monitor patient closely for evidence of GI bleeding, especially if patient takes another drug known to increase the risk, such as aspirin, an NSAID, or warfarin.
- Monitor patient—especially an elderly patient—for hyposmolarity of serum and urine and for hyponatremia (difficulty concentrating, headache, memory impairment, unsteadiness, weakness), which may indicate fluoxetine-induced SIADH.
- Expect to taper drug when being discontinued, as ordered, to minimize adverse reactions.

**WARNING** Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching, especially if patient is receiving another drug that raises serotonin level (such as amphetamine, dopamine agonist, MAO inhibitor, tryptophan, or other antidepressant or psychostimulant). In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes autonomic instability, high fever, muscle rigidity, and possible fluctuations in vital signs and mental status.

- Monitor patient with diabetes mellitus for altered blood glucose level because drug may cause hypoglycemia during therapy and hyperglycemia when it stops. Expect to adjust dosage of antidiabetic drug, as prescribed.
- Expect patient to be reevaluated periodically to determine continued need for therapy.

## PATIENT TEACHING

**WARNING** Tell patient that drug increases risk of serotonin syndrome, a rare but serious complication, especially when taken with certain other drugs. Teach patient to recognize its signs and symptoms, and advise her to notify prescriber immediately if they occur.

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes, and particularly if patient is a child, teenager, or young adult.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.
- Caution against stopping fluoxetine abruptly because serious adverse effects may result.
- Instruct patient to notify prescriber of any persistent, severe, or unusual signs or symptoms while taking fluoxetine.
- Inform patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage patient to have an eye exam prior to starting fluoxetine therapy to see if she is at risk.
- Advise patient to consult prescriber before taking OTC or prescription drugs, if hives or a rash develop.
- Urge women of childbearing age to notify prescriber if pregnancy is suspected or occurs, because fluoxetine therapy may increase risk of serious adverse effects in the newborn. Have patient discuss alternative treatment for depression during pregnancy, explaining that coming off an antidepressant during pregnancy may cause her depression to relapse. Also tell mothers that fluoxetine is excreted in breast milk, so breastfeeding is not recommended while taking drug.
- Inform patient that drug may take several weeks to achieve full effects.

**fluphenazine decanoate**

# Modecate (CAN), Modecate Concentrate (CAN)

## fluphenazine hydrochloride

### Class and Category

*Pharmacologic class:* Phenothiazine *Therapeutic class:* Antipsychotic

### Indications and Dosages

➤ *To control psychotic disorders*

#### ELIXIR, I.M. INJECTION, ORAL SOLUTION, TABLETS (FLUPHENAZINE HYDROCHLORIDE)

**Adults and adolescents.** *Initial:* 2.5 to 10 mg/day in divided doses every 6 to 8 hr. *Maintenance:* 1 to 5 mg daily in divided doses every 6 to 8 hr. *Maximum:* 40 mg/day.

***DOSAGE ADJUSTMENT*** For elderly or debilitated patients, initial oral dosage reduced to 1 to 2.5 mg daily in divided doses every 6 to 8 hr.

#### I.M. OR SUBCUTANEOUS INJECTION (FLUPHENAZINE DECANOATE)

**Adults.** *Initial:* 12.5 to 25 mg given every 2 to 4 weeks or longer depending on patient's needs. For doses over 50 mg, next dose increased cautiously by 12.5 mg. *Maximum:* 100 mg/dose.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

Route	Onset	Peak	Duration
P.O.	In 1 hr	Variable	6–8 hr
I.M.*	In 1 hr	Variable	6–8 hr
I.M., SubQ <sup>†</sup>	In 24–72 hr	Variable	1–6 wk <sup>‡</sup>

\* For hydrochloride.

<sup>†</sup> For decanoate.

<sup>‡</sup> For decanoate.

## Mechanism of Action

May block postsynaptic dopamine receptor sites in the CNS. This action may depress areas of the brain that control activity and aggression, including the cerebral cortex, hypothalamus, and limbic system.

## Incompatibilities

Don't mix fluphenazine hydrochloride oral solution with beverages that contain caffeine, such as coffee and cola; pectins, such as apple juice; or tannins, such as tea. They're physically incompatible.

## Contraindications

Blood dyscrasias; coma; concomitant use of large amounts of another CNS depressant; hepatic dysfunction; hypersensitivity to fluphenazine, other phenothiazines, or their components; narrow angle glaucoma; poorly controlled seizure disorder, severe cardiovascular disease, CNS depression or hypertension; subcortical brain damage

## Interactions

## DRUGS

*adsorbent antidiarrheals, aluminum- or magnesium-containing antacids:* Possibly inhibited absorption of fluphenazine

*anticholinergics:* Possibly intensified adverse effects of both drugs

*antihypertensives:* Possibly severe hypotension

*barbiturates, CNS depressants, opioids:* Possibly prolonged and intensified CNS depression and respiratory depression

*lithium:* Possibly neurotoxicity (disorientation, extrapyramidal reactions, unconsciousness)

## ACTIVITIES

*alcohol use:* Possibly increased CNS and respiratory depression that may become severe

## Adverse Reactions

**CNS:** Ataxia, **cerebral edema**, dizziness, drowsiness, headache, insomnia, light-headedness, nervousness, **seizures**, slurred speech, syncope, worsening psychotic symptoms

**CV:** **AV conduction disorders**, **bradycardia**, **cardiac arrest**, hypercholesterolemia, hypertension, orthostatic hypotension, **QT-interval prolongation**, **shock**, **ST-segment depression**, tachycardia

**EENT:** Blurred vision, dry mouth, glaucoma, increased salivation, **laryngeal edema**, **laryngospasm**, miosis, mydriasis, nasal congestion, papillary hypertrophy of the tongue, parotid gland enlargement, photophobia, pigmentary retinopathy, ptosis

**ENDO:** Breast engorgement (females), galactorrhea, hyperglycemia, **hypoglycemia**, mastalgia, syndrome of inappropriate ADH secretion

**GI:** Anorexia, constipation, diarrhea, fecal impaction, ileus, increased appetite, jaundice, nausea, vomiting

**GU:** Amenorrhea, bladder paralysis, decreased libido, enuresis, menstrual irregularities, polyuria, urinary frequency, urinary incontinence, urine retention

**HEME:** Anemia, **aplastic anemia**, eosinophilia, **leukopenia**, **nonthrombocytopenic or thrombocytopenic purpura**, **thrombocytopenia**

**RESP:** **Bronchospasm**, dyspnea, increased respiratory depth

**SKIN:** Contact dermatitis, dry skin, eczema, erythema, photosensitivity, pruritus, seborrhea

**Other:** **Heatstroke**, **hyponatremia**, lupus-like symptoms, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but may have an adverse effect on the fetus if administered during the third trimester of pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Neonates exposed to antipsychotics during the third trimester of pregnancy may develop extrapyramidal and withdrawal signs and symptoms after delivery.

## **LACTATION**

- Drug maybe present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Be aware that fluphenazine shouldn't be used to treat dementia-related psychosis in elderly patients because of an increased mortality risk.
- Use fluphenazine cautiously in patients with a history of glaucoma or renal impairment.
- For I.M. and subcutaneous injection, use at least a 21G needle.
- Monitor temperature; a significant, unexplained rise can indicate intolerance and a need to discontinue drug. Notify prescriber immediately if this occurs.
- Watch for signs of hepatic failure, such as jaundice.
- Notify prescriber about worsening psychotic symptoms: agitation, catatonic state, confusion, depression, hallucinations, lethargy, paranoid reactions.

## **PATIENT TEACHING**

- Instruct patient prescribed elixir form of fluphenazine to keep it in an amber or opaque bottle because drug is sensitive to light.
- Advise patient not to mix oral solution with beverages that contain caffeine (coffee, cola), pectins (apple juice), or tannins (tea).
- Caution patient about possible dizziness or light-headedness.
- Teach patient how to prevent heatstroke, orthostatic hypotension, and photosensitivity reactions.
- Warn against stopping drug abruptly.

# flurazepam hydrochloride

## Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Sedative-hypnotic

*Controlled substance schedule:* IV

## Indications and Dosages

- *To treat insomnia characterized by difficulty falling asleep, frequent nocturnal awakenings, or early-morning awakening*

### CAPSULES

**Adult women.** *Initial:* 15 mg at bedtime, increased to 30 mg at bedtime, as needed.

**Adult men.** *Initial:* 15 or 30 mg at bedtime. Dosage may be increased to 30 mg at bedtime, as needed, if initial dose was 15 mg.

***DOSAGE ADJUSTMENT*** Initial dose not to exceed 15 mg for elderly or debilitated men until individual response is known.

Route	Onset	Peak	Duration
P.O.	15-45 min	Unknown	7-8 hr

## Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding

to specific benzodiazepine receptor sites in the cortical and limbic areas of the CNS. As a result, flurazepam increases GABA's inhibitory effects and blocks cortical and limbic arousal.

## **Contraindications**

Hypersensitivity to flurazepam, other benzodiazepines, or their components

## **Interactions**

### **DRUGS**

*CNS depressants:* Possibly potentiated CNS depression  
*opioids:* Increased risk of profound CNS and respiratory depression and sedation

### **ACTIVITIES**

*alcohol use:* Possibly potentiated CNS and respiratory depression

## **Adverse Reactions**

**CNS:** Amnesia, anxiety, ataxia, bizarre behavior (such as sleep driving), confusion, delusions, depression, dizziness, drowsiness, euphoria, headache, hypokinesia, irritability, malaise, nervousness, slurred speech, tremor

**CV:** Chest pain, palpitations, tachycardia

**EENT:** Blurred vision, dry mouth, increased salivation, photophobia

**GI:** Abdominal pain, constipation, diarrhea, nausea, thirst, vomiting

**GU:** Libido changes

**SKIN:** Diaphoresis

**Other:** **Anaphylaxis, angioedema**, physical or psychological dependence

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Infants born to mothers who have taken the drug during the later stages of pregnancy can develop dependence, and subsequently withdrawal, during the postnatal period.
- Use with extreme caution only if benefit to mother outweighs potential risk to fetus. If possible, drug should not be used during pregnancy.

### LABOR & DELIVERY

- Administration of drug immediately prior to or during childbirth can result in a syndrome of hypothermia, hypotonia, respiratory depression, and difficulty feeding for the infant.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use flurazepam cautiously in patients with severe mental depression or reduced respiratory function; drug may intensify mental depression and lead to respiratory depression.

- Expect to use lowest effective dose in debilitated or elderly patients to minimize the risk of ataxia, confusion, dizziness, and oversedation.
- Monitor liver function test results, as appropriate.

## PATIENT TEACHING

- Instruct patient not to exceed prescribed dosage and not to stop drug abruptly.

**WARNING** Warn patient that, although rare, drug may cause swelling of the oral cavity or throat, which could cause airway obstruction. If swelling occurs, patient should seek emergency care immediately and never take flurazepam again.

- Caution patient about possible morning dizziness or drowsiness.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Caution patient to avoid alcohol and CNS depressants during therapy.
- Advise patient to notify prescriber if she becomes or intends to become pregnant during therapy.
- Inform patient that sleep may be disturbed for the first few nights after stopping drug.
- Warn patient and caregiver that some patients have performed bizarre activities after taking drug, such as driving a car, eating food, having sex, or making phone calls while not fully awake and often with no memory of the event. These episodes usually occur in patients who have taken the drug with alcohol or other CNS depressant or who have exceeded the recommended dose. If such an episode occurs, the prescriber should be notified and flurazepam therapy discontinued immediately.

**fluticasone propionate**

**Armonair Respiclick, Flonase,  
Flonase Allergy Relief, Flovent  
Diskus, Flovent HFA, Xhance**

**fluticasone furoate**

**Arnuity Ellipta, Flonase Sensimist,  
Veramyst**

## **Class and Category**

*Pharmacologic class:* Corticosteroid

*Therapeutic class:* Antiasthmatic, anti-inflammatory

## **Indications and Dosages**

- *To prevent asthma attacks, alone or with oral corticosteroids as maintenance therapy*

### **INHALATION AEROSOL (FLOVENT HFA)**

**Adults and children age 12 and over not on an inhaled corticosteroid.** *Initial:* 88 mcg twice daily, about 12 hr apart. After 2 wk, dosage may be increased, as needed. *Maximum:* 880 mcg twice daily.

**Adults and children age 12 and over previously taking other corticosteroids.** Initial dosage highly individualized and based on previous asthma therapy and severity. After 2 wks, dosage may be increased, as needed. *Maximum:* 880 mcg twice daily.

**Children ages 4 to 11 regardless of previous therapy.** 88 mcg inhaled twice daily. *Maximum:* 88 mcg twice daily.

## **INHALATION AEROSOL (FLOVENT DISKUS)**

**Adults and children age 12 and over not on an inhaled corticosteroid.** *Initial:* 100 mcg twice daily, about 12 hr apart. After 2 wk, dosage may be increased, as needed.

*Maximum:* 1,000 mcg twice daily.

**Adults and children age 12 and over previously taking other corticosteroids.** Initial dosage highly individualized and based on previous asthma therapy and severity. After 2 wks, dosage may be increased, as needed. *Maximum:* 1,000 mcg twice daily.

**Children ages 4 to 11 not taking an inhaled corticosteroid.** *Initial:* 50 mcg inhaled twice daily, increased as needed to 100 mcg twice daily. *Maximum:* 100 mcg inhaled twice daily.

**Children ages 4 to 11 taking other corticosteroids:** Initial dosage highly individualized based on previous asthma therapy and severity. After 2 wks, dosage may be increased to 100 mcg twice daily. *Maximum:* 100 mcg twice daily

## **INHALATION AEROSOL (ARMONAIR RESPICLICK)**

**Adults not on inhaled corticosteroids.** 55 mcg inhaled twice daily.

**Adults switching from another inhaled corticosteroid.** Individualized based upon strength of previous inhaled corticosteroid and disease severity. Dosage may be low at 55 mcg inhaled twice daily, medium at 113 mcg inhaled twice daily, or high at 232 mcg inhaled twice daily, with dosage increase for lower dosages after 2 wk, if needed. *Maximum:* 232 mg inhaled twice daily.

## **INHALATION AEROSOL (ARNUITY ELLIPTA)**

**Adults and children age 12 and older not on inhaled corticosteroid therapy.** 100 mcg inhaled once daily, increased after 2 wk to 200 mcg once daily, as needed.

**Adults and children age 12 and older receiving other drug treatments for asthma.** Highly individualized based on patient's previous asthma drug therapy and disease severity.

**Children age 5 to 12.** 50 mcg inhaled once daily.

- *To manage nasal symptoms of perennial nonallergic rhinitis*

## **NASAL SUSPENSION (FLONASE, FLONASE ALLERGY RELIEF)**

**Adults.** *Initial:* 100 mcg (2 sprays) in each nostril once daily or 50 mcg (1 spray) in each nostril twice daily about 12 hr apart. *Maximum:* 100 mcg (2 sprays) in each nostril daily.

**Children ages 4 and over.** 50 mcg (1 spray) in each nostril daily, increased, as needed, to 100 mcg (2 sprays) in each nostril daily. *Maximum:* 100 mcg (2 sprays) in each nostril daily.

- *To treat perennial and seasonal allergic rhinitis*

## **NASAL SUSPENSION (VERAMYST)**

**Adults and children age 12 and over.** *Initial:* 55 mcg (2 sprays) in each nostril once daily. *Maintenance:* 27.5 mcg (1 spray) in each nostril once daily.

**Children ages 2 to 11.** *Initial:* 27.5 mcg (1 spray) in each nostril once daily, increased to 55 mcg (2 sprays) in each nostril once daily, as needed. *Maintenance:* 27.5 mcg (1 spray) in each nostril once daily.

## **NASAL SUSPENSION (FLONASE SENSIMIST)**

**Adults and children ages 12 and over.** *Initial:* 55 mcg (2 sprays) in each nostril once daily for 1 wk. Beginning wk 2 through 6 mo, 27.5 or 55 mcg (1 to 2 sprays) in each nostril once daily.

**Children ages 2 to 11.** 27.5 mcg (1 spray) in each nostril daily.

➤ *To treat nasal polyps*

## NASAL SPRAY (XHANCE)

**Adults.** 1 spray (93 mcg) in each nostril twice daily, increased to 2 sprays (186 mcg) in each nostril twice daily, if needed. *Maximum:* 2 sprays (186 mcg) in each nostril twice daily for total daily dose of 744 mcg.

Route	Onset	Peak	Duration
Inhalation	In 24 hr	1-2 wk	Several days
Nasal	12 hr-3 days	4-7 days	1-2 wk

## Mechanism of Action

Inhibits cells involved in the inflammatory response of asthma, such as basophils, eosinophils, lymphocytes, macrophages, mast cells, and neutrophils. Fluticasone also inhibits production or secretion of chemical mediators, such as cytokines eicosanoids, histamine, and leukotrienes.

## Contraindications

Hypersensitivity to fluticasone or its components, or to milk proteins; primary treatment of status asthmaticus or other acute asthma episodes that require intensive measures (inhalation form); untreated nasal mucosal infection (nasal suspension)

# Interactions

## DRUGS

*strong CYP3A4 inhibitors such as atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin:*  
Possibly increased fluticasone level with increased risk of corticosteroid adverse effects

## Adverse Reactions

**CNS:** Aggressiveness, agitation, anxiety, depression, difficulty speaking, dizziness, fatigue, fever, headache, insomnia, irritability, malaise, restlessness

**EENT:** Allergic rhinitis, blurred vision, cataracts, central serous chorioretinopathy, conjunctivitis, dental caries, difficulty speaking, dry mouth and throat, epistaxis, esophageal candidiasis, eye irritation, facial and **oropharyngeal edema**, glaucoma, hoarseness, impaired nasal wound healing, laryngitis, loss of voice, nasal *Candida* infection, nasal congestion or discharge, nasal discomfort (burning, dryness, irritation, soreness), nasal sinus pain, nasal septal perforation or ulceration, nasopharyngitis, oropharyngeal candidiasis, otitis media, pharyngitis, rhinitis, sinusitis, throat irritation, tonsillitis, tooth discoloration

**ENDO:** **Adrenal insufficiency**, cushingoid symptoms, hyperglycemia, slower growth in children

**GI:** Abdominal pain, diarrhea, indigestion, nausea, vomiting

**GU:** Dysmenorrhea

**HEME:** **Churg-Strauss syndrome**, easy bruising, eosinophilia

**MS:** Arthralgia, back pain, bone mineral density reduction (long-term use), myalgia, osteoporosis

**RESP:** **Asthma exacerbation**, bronchitis, **bronchospasm**, chest congestion and tightness, cough, dyspnea, pneumonia, upper respiratory tract infection, wheezing

**SKIN:** Dermatitis, ecchymosis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use fluticasone cautiously in patients with ocular herpes simplex, pulmonary tuberculosis, or untreated systemic bacterial, fungal, parasitic, or viral infection. Also, use cautiously in patients with moderate or severe hepatic impairment.
- Monitor patient closely at start of therapy, especially if patient has severe allergy to milk. If hypersensitivity reaction occurs, notify prescriber, expect drug to be discontinued, and provide supportive care, as prescribed.
- Know that if patient takes a systemic corticosteroid, expect to taper dosage by no more than 2.5 mg daily at weekly intervals, starting 1 week

after fluticasone therapy begins.

**WARNING** Be aware that if patient is switched from systemic corticosteroid to fluticasone, assess for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) early in therapy and when patient has infection, stress, surgery, trauma, or other electrolyte-depleting conditions or procedures. Notify prescriber immediately if signs or symptoms develop. Also, be aware that the patient should be weaned slowly from systemic corticosteroid use. For example, expect to reduce daily prednisone dose by 2.5 mg on a weekly basis with fluticasone therapy.

- Administer a fast-acting inhaled bronchodilator, as ordered, if bronchospasm occurs immediately after fluticasone use. Expect to stop fluticasone and start another drug therapy.
- Expect to titrate fluticasone to lowest effective dosage after asthma has stabilized.
- Notify prescriber if patient develops ocular adverse reactions because fluticasone therapy may cause many (cataracts, increased intraocular pressure, and glaucoma) that should be checked by an ophthalmologist.

## **PATIENT TEACHING**

- Urge patient to use fluticasone regularly, as prescribed, and stress that drug is not for acute bronchospasm. Instruct her to have a rescue inhaler accessible if acute bronchospasm occurs.
- Teach patient how to administer drug according to the form prescribed (nasal spray or oral inhaler).
- Inform patient that Armonair Respiclick brand of fluticasone does not require priming and should not be used with a spacer or volume holding chamber. Instruct patient to shake canister for other forms of inhaled fluticasone products and use inhaler according to package instructions. On first use, advise her to spray 4 times into the air (away from her eyes and shaking inhaler between each test spray) looking for a fine mist. If inhaler hasn't been used for more than 7 days or it's dropped, it will need

to be primed again by shaking well and then releasing 1 test spray into the air (away from her face).

- Tell patient prescribed 2 inhalations to wait at least 1 minute between them.
- Instruct patient to gargle and rinse her mouth after each dose of an oral inhaler to help prevent dry mouth and throat and oropharyngeal yeast infection and relieve throat irritation.
- Instruct patient prescribed more than 1 inhaler to use fluticasone last, at least 5 minutes after previous inhaler.
- Instruct patient to clean inhaler according to manufacturer guidelines at least once a week after her evening dose. Alert patient prescribed Armonair Respiclick brand never to wash or put any part of the inhaler in water, as routine maintenance is not required. Tell patient that if the mouthpiece needs cleaning, gently wipe the mouthpiece with a dry cloth or tissue.
- Inform patient that, when counter reads 020 on the inhaler, she should obtain a refill, if needed. When counter reaches 000, she should discard the inhaler.
- Instruct patient using nasal spray to shake container well before each use. If patient is using Xhance form of nasal spray, tell her to prime the container before initial use by first gently shaking and then pressing the bottle 7 times or until a fine mist appears. Tell patient if the container is not used for 7 days or more, the container will have to be reprimed by shaking and releasing 2 sprays into the air, away from the face.
- Explain that symptoms may improve within 2 days but that full improvement may not occur for 1 to 2 weeks or longer.
- Caution patient not to increase dosage but to contact prescriber after 1 week if symptoms continue or worsen.
- Urge patient to tell prescriber immediately if asthma attacks don't respond to bronchodilators during fluticasone therapy.
- Know that if patient is switching from an oral corticosteroid to fluticasone, urge her to carry medical identification indicating the need for supplemental systemic corticosteroids during stress or severe asthma attack.
- Caution patient to avoid people who have infections because fluticasone suppresses the immune system, increasing the risk of infection. Instruct patient to notify prescriber about exposure to chickenpox, measles, or other infections because additional treatment may be needed.
- Instruct patient to report ocular adverse reactions to prescriber.

# fluvastatin sodium

**Lescol, Lescol XL**

## Class and Category

*Pharmacologic class:* HMG-CoA reductase inhibitor

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *As adjunct to lower cholesterol level in primary hypercholesterolemia and mixed dyslipidemia (Fredrickson Type IIa and II b) in patients whose response to dietary restriction and other nonpharmacologic measures has been inadequate; to decrease progression of coronary atherosclerosis; to reduce risk in patients with coronary artery disease undergoing coronary revascularization*

## CAPSULES

**Adults.** 20 to 40 mg daily in the evening, increased up to 40 mg twice daily, as needed. *Maximum:* 40 mg twice daily.

## E.R. TABLETS

**Adults.** 80 mg once daily at any time of day. *Maximum:* 80 mg daily.

- *As adjunct to lower cholesterol level in children with heterozygous familial hypercholesterolemia whose LDL-C remains 190 mg/dl or greater or whose LDL-C*

*remains 160 mg/dl or greater combined with a positive family history of premature cardiovascular disease or two or more other cardiovascular disease risk factors are present*

## CAPSULES

**Boys and girls (who are at least 1 year past menarche) ages 10 to 16.** *Initial:* 20 mg once daily, increased every 6 wk, as needed. *Maximum:* 40 mg twice daily.

***DOSAGE ADJUSTMENT*** For pediatric patients, if maximum dose of 40 mg twice daily is reached with immediate-release capsules, child may be switched to extended-release tablets, 80 mg once daily. For patients taking cyclosporine or fluconazole, dosage not to exceed 20 mg twice daily.

Route	Onset	Peak	Duration
P.O.	In 1-2 wk	In 4-6 wk	Unknown
P.O. (E.R.)	In 2 wk	In 4 wk	Unknown

## Mechanism of Action

Interferes with the hepatic enzyme hydroxymethylglutaryl-coenzyme A reductase, reducing formation of mevalonic acid (a cholesterol precursor) and interrupting the pathway by which cholesterol is synthesized. When cholesterol level declines in hepatic cells, LDLs are consumed, which reduces circulating total cholesterol and serum triglycerides.

## Contraindications

Acute hepatic disease, hypersensitivity to fluvastatin or its components, pregnancy or in women who may become

pregnant, unexplained persistently elevated liver enzyme levels

## Interactions

### DRUGS

*colchicine, cyclosporine, erythromycin, gemfibrozil, niacin, other fibrates*: Increased risk of severe myopathy and rhabdomyolysis

*cyclosporine, fluconazole, glyburide, phenytoin*: Increased drug levels of these drugs

*protease inhibitors*: Possible increased blood fluvastatin level; possible increased risk of myopathy and rhabdomyolysis

*rifampin*: Significantly decreased blood fluvastatin level, increased plasma clearance

*warfarin*: Possibly increased bleeding and/or increased prothrombin times

### ACTIVITIES

*alcohol use*: Increased risk of liver dysfunction

## Adverse Reactions

**CNS**: Dizziness, fatigue, headache, hypoesthesia, insomnia, memory loss, weakness

**EENT**: Pharyngitis, rhinitis, sinusitis

**ENDO**: **Adrenal insufficiency**, decreased gonadal steroid hormone production, elevated hemoglobin A1c levels, hyperglycemia

**GI**: Abdominal cramps and pain, anorexia, **cirrhosis**, constipation, diarrhea, elevated liver enzymes, flatulence,

**fulminant hepatic necrosis, hepatic failure, hepatitis, hepatoma**, hyperbilirubinemia, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU:** UTI

**MS:** Arthritis, back pain, immune-mediated necrotizing myopathy, muscle pain, myalgia, myopathy, myositis, **rhabdomyolysis**

**RESP:** Bronchitis, cough, **interstitial lung disease**, upper respiratory tract infection

**SKIN:** Pruritus, rash

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm because cholesterol and cholesterol derivatives are needed for normal fetal development.
- Drug is contraindicated in pregnant women or women who may become pregnant.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

**WARNING** Expect to stop drug if CK level rises sharply or myopathy is suspected.

- Expect liver enzymes to be checked before fluvastatin therapy starts and then thereafter as clinically necessary.

- Assess patient for signs and symptoms of hepatic dysfunction such as dark urine or jaundice, fatigue, and/or elevation in liver enzymes to more than 3 times the upper limit of normal. Also look for hyperbilirubinemia. If present, notify prescriber and expect fluvastatin to be discontinued until cause of liver dysfunction has been identified. If no cause can be found, expect the drug to be discontinued permanently.
- Monitor patient for hyperglycemia, especially diabetic patients, and for other endocrine signs and symptoms. Notify prescriber, if present.

## PATIENT TEACHING

- Urge patient to comply with monthly laboratory tests early in treatment.
- Tell patient to follow prescribed low-fat diet.
- Encourage patient to notify prescriber promptly about muscle pain or unexplained weakness.
- Instruct patient with diabetes to monitor his blood glucose level more closely.

# fluvoxamine maleate

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat obsessive-compulsive disorder*

## TABLETS

**Adults.** *Initial:* 50 mg at bedtime, increased by 50 mg every 4 to 7 days, as needed. *Maximum:* 300 mg daily, with doses greater than 100 mg daily given as 2 divided doses and if doses are not equal, larger dose given at bedtime.

**Children ages 8 to 17.** *Initial:* 25 mg at bedtime, increased by 25 mg every 4 to 7 days, as needed. *Maximum:* 200 mg daily (children ages 8 to 11) and 300 mg daily (children ages 11 to 17), with doses greater than 50 mg daily divided into 2 doses, and if not divided equally, larger dose given at bedtime.

## E.R. CAPSULES

**Adults.** *Initial:* 100 mg at bedtime, increased by 50 mg weekly, if needed. *Maximum:* 300 mg daily.

**DOSAGE ADJUSTMENT** For elderly patients or those with hepatic impairment, initial dosage decreased for immediate-release form and dosage increases made more slowly for both immediate-release and extended-release forms.

Route	Onset	Peak	Duration
P.O.	3-10 wk	Unknown	Unknown

## Mechanism of Action

May potentiate serotonin's action by blocking its reuptake at neuronal membranes. An elevated serotonin level may elevate mood and decrease depression and anxiety, which often accompany obsessive-compulsive disorder.

## Contraindications

Alosetron, pimozide, thioridazine, or tizanidine therapy; hypersensitivity to fluvoxamine maleate or its components;

use within 14 days of MAO inhibitor, including intravenous methylene blue and linezolid

## Interactions

### DRUGS

*aloseptron, antipsychotics, benzodiazepines, tacrine, ramelteon, tricyclic antidepressants*: Elevated plasma levels of these drugs with increased risk of adverse reactions  
*amphetamines, busipirone, fentanyl, linezolid, lithium, methylene blue (intravenous), other serotonergic drugs, St. John's wort, tramadol, tricyclic antidepressants, triptans, tryptophan*: Increased risk of serotonin syndrome  
*aspirin, NSAIDs, warfarin*: Risk of bleeding  
*astemizole, cisapride, pimozide, terfenadine, thioridazine*: Possibly fatal QT prolongation  
*carbamazepine*: Increased risk of carbamazepine toxicity  
*clozapine*: Increased blood clozapine level increasing risk of orthostatic hypotension and seizures  
*diltiazem*: Increased risk of bradycardia  
*lithium*: Possibly increased serotonin reuptake action of fluvoxamine and increased risk of seizures  
*MAO inhibitors*: Possibly serious or fatal reactions (such as agitation, autonomic instability, coma, delirium, fluctuating vital signs, hyperthermia, myoclonus, and rigidity); increased risk of serotonin syndrome  
*methadone*: Possibly significantly increased blood methadone level, increased risk of methadone toxicity  
*metoprolol, propranolol, and other beta blockers*: Increased blood levels of these drugs, possibly reduced diastolic blood pressure and heart rate induced by these drugs  
*mexiletine*: Possibly decreased clearance of mexiletine  
*pimozide, thioridazine*: Increased plasma levels of these drugs with increased risk of QT interval associated with

serious ventricular arrhythmias

*sumatriptan*: Increased risk of hyperreflexia, incoordination, and weakness

*theophylline*: Decreased theophylline clearance, increased risk of theophylline toxicity

*tizanidine*: Increased risk of serious adverse effects, such as hypotension and profound sedation

*tryptophan*: Enhanced effect of tryptophan and possibly induced severe vomiting

*warfarin*: Significant increased plasma level of warfarin with prolonged prothrombin time

## ACTIVITIES

*alcohol*: Possibly increased CNS effects

*smoking*: Increased fluvoxamine metabolism

## Adverse Reactions

**CNS**: Agitation, anxiety, apathy, chills, confusion, depression, dizziness, drowsiness, fatigue, headache, hypomania, insomnia, malaise, mania, nervousness, **neuroleptic malignant syndrome**, sedation, **serotonin syndrome**, **suicidal ideation**, tremor, vertigo, yawning

**CV**: Palpitations, tachycardia, vasculitis, **ventricular tachycardia**

**EENT**: Acute-angle glaucoma, altered taste, blurred vision, dry mouth

**GI**: Anorexia, constipation, diarrhea, flatulence, **hepatitis**, ileus, indigestion, nausea, **pancreatitis**, **upper GI bleeding**, vomiting

**GU**: **Acute renal failure**, amenorrhea, decreased libido, ejaculation disorders, impotence, urinary frequency, urine

retention

**HEME:** Agranulocytosis, aplastic anemia, bleeding events

**MS:** Muscle twitching

**RESP:** Dyspnea, upper respiratory tract infection

**SKIN:** Bullous eruption, diaphoresis, Henoch-Schoenlein purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, angioedema, flu-like symptoms, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-844-405-6185 or <https://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/antidepressants/>.
- It is not known if drug causes fetal harm but may have adverse effects if given late in third trimester.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Fetal exposure to drug late in third trimester may cause neonatal complications as soon as birth.
- Complications such as persistent pulmonary hypertension of the newborn may require prolonged hospitalization, respiratory support, and tube feeding.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for agitation, decreased sleep, diarrhea, and vomiting.

## REPRODUCTION

- Fertility may be impaired while taking drug according to animal studies.

## Nursing Considerations

- Use fluvoxamine cautiously in patients with cardiovascular disease, impaired hepatic or renal function, mania, seizures, or suicidal tendencies.

**WARNING** Be aware that fluvoxamine shouldn't be given within 14 days of an MAO inhibitor.

**WARNING** Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching, especially if patient is receiving another drug that raises serotonin level (such as amphetamine, dopamine agonist, MAO inhibitor, tryptophan, or other antidepressant or psychostimulant). In its most severe form, serotonin syndrome can resemble neuroleptic malignant syndrome, which includes autonomic instability, a high fever, muscle rigidity, and possible fluctuations in vital signs and mental status.

- Watch patient closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times and lead to suicidal ideation.

- Monitor patient for bleeding, especially if patient also takes aspirin, an anticoagulant, or NSAID. Bleeding can range from ecchymoses, epistaxis, hematomas, and petechiae to life-threatening hemorrhage.
- Discontinue fluvoxamine therapy gradually, as ordered, to prevent unpleasant adverse reactions.

## PATIENT TEACHING

- Caution patient not to drink alcohol during fluvoxamine therapy.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.

**WARNING** Inform patient that fluvoxamine increases the risk of a rare but serious problem: serotonin syndrome. Encourage her to notify prescriber immediately if symptoms develop.

- Caution patient not to stop taking drug abruptly. Explain that gradual tapering helps avoid withdrawal symptoms.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.
- Warn patient that fluvoxamine increases bleeding risk if taken with an anticoagulant, aspirin, or an NSAID and that bleeding events could range from mild to severe. Tell patient to seek emergency care for serious or prolonged bleeding.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-angle glaucoma. Encourage patient to have an eye exam before starting therapy to see if she is at risk.

**WARNING** Advise pregnant patient to consult with prescriber before her third trimester about ongoing fluvoxamine therapy because of an increased risk to her unborn child during the third trimester.

# fondaparinux sodium

**Arixtra**

## Class and Category

*Pharmacologic class:* Activated factor X inhibitor

*Therapeutic class:* Anticoagulant

## Indications and Dosages

- *To provide prophylaxis against deep vein thrombosis, which may lead to pulmonary embolism in patients undergoing abdominal surgery, hip fracture surgery, hip replacement surgery, or knee replacement surgery in patients at risk for thromboembolic complications*

### SUBCUTANEOUS INJECTION

**Adults. Initial:** After hemostasis has been established, 2.5 mg subcutaneously 6 to 8 hr after surgery, followed by 2.5 mg subcutaneously daily for 5 to 9 days, except for hip fracture surgery which may be given up to 24 additional days for a total of 32 days.

- *To treat acute deep vein thrombosis (with warfarin); to treat acute pulmonary embolism (with warfarin) in a hospital setting*

### SUBCUTANEOUS INJECTION

**Adults weighing more than 100 kg (220 lb).** 10 mg daily for at least 5 days and until INR is between 2.0 and 3.0 (usually in 5 to 9 days).

**Adults weighing 50 kg (110 lb) to 100 kg (220 lb).** 7.5 mg daily for at least 5 days and until INR is between 2.0 and 3.0 (usually in 5 to 9 days).

**Adults weighing less than 50 kg (110 lb).** 5 mg daily for at least 5 days and until INR is between 2.0 and 3.0 (usually in 5 to 9 days).

## **Mechanism of Action**

Selectively binds to antithrombin III, which enhances the inactivation of clotting factor Xa by antithrombin III. Inactivation of factor Xa interrupts the blood coagulation pathway, which then inhibits thrombin formation. Without thrombin, fibrinogen can't convert to fibrin and clots can't form.

## **Incompatibilities**

Don't mix fondaparinux sodium with other infusions or injections.

## **Contraindications**

Active major bleeding; bacterial endocarditis; body weight less than 50 kg (110 lb) for venous thromboembolism prophylaxis; fondaparinux-induced thrombocytopenia associated with a positive in vitro test for antiplatelet antibodies; hypersensitivity to fondaparinux or its components; severe renal impairment (creatinine clearance less than 30 ml/min)

## **Interactions**

### **DRUGS**

*drugs that increase risk of bleeding:* Increased risk of hemorrhage and epidural or spinal hematoma

## Adverse Reactions

**CNS:** Confusion, dizziness, fever, headache, insomnia

**CV:** Edema, elevated serum aminotransferase level, **hypotension**

**GI:** Constipation, diarrhea, elevated liver enzymes, indigestion, nausea, vomiting

**GU:** Urine retention, UTI

**HEME:** Anemia, **bleeding**, **elevated APTT**, hematoma, **hemorrhage**, **thrombocytopenia**, **thrombocytopenia with thrombosis**

**SKIN:** Bullous eruption, increased wound drainage, purpura, rash

**Other:** **Anaphylaxis**; **angioedema**; generalized pain; **hypokalemia**; injection-site bleeding, pruritus, and rash

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but drug does cross the placental barrier, which may increase risk of bleeding in the fetus and neonate.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Increased risk of bleeding during labor and delivery and epidural or spinal hematomas if neuraxial anesthesia is used.

- A shorter acting anticoagulant may be substituted as delivery approaches.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use fondaparinux cautiously in elderly patients, especially those weighing less than 50 kg (110 lb) and are receiving the drug for pulmonary embolism or deep vein thrombosis, because the risk of drug-induced bleeding increases with age.
- Don't give initial dose of fondaparinux less than 6 hours after surgery.
- Inspect fondaparinux for discoloration or particles before administration. Be aware that needle guard on prefilled syringe contains dry natural latex rubber and shouldn't be handled by those sensitive to latex.
- Alternate injection sites using left and right anterolateral or left and right posterolateral abdominal wall. Don't expel air bubble from prefilled syringe before injection to prevent expelling drug from syringe. Don't give drug by I.M. injection.

**WARNING** Know that if patient is receiving fondaparinux with epidural or spinal anesthesia or spinal puncture, patient must be watched closely for development of spinal hematoma, which may cause long-term or permanent paralysis. If evidence of neurologic impairment, such as changes in motor or sensory function occurs, notify prescriber immediately because urgent care is needed to minimize hematoma's effect. Risk of spinal or epidural hematoma during fondaparinux therapy is increased by concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery as well as indwelling epidural catheters. Be aware that optimal

timing between the administration of fondaparinux and neuraxial procedures is unknown.

- Closely monitor patient for bleeding (such as ecchymosis, epistaxis, hematemesis, hematuria, and melena), especially those at risk for decreased drug elimination (such as elderly patients and patients with mild to moderate renal impairment) and those at increased risk for bleeding (such as patients with acquired or congenital bleeding disorders; active ulcerative and angiodysplastic GI disease; diabetic retinopathy; hemorrhagic stroke; uncontrolled arterial hypertension; recent brain, spinal, or ophthalmologic surgery; history of heparin-induced thrombocytopenia; and those being treated concomitantly with platelet inhibitors). Also monitor neonates born to mothers taking fondaparinux for bleeding, because drug does cross the placenta.
- Perform periodic CBC, including platelet count, as ordered. Expect prescriber to discontinue drug if platelet count falls below  $100,000/\text{mm}^3$ . Be aware that routine coagulation tests, such as INR and PT, are not used to monitor fondaparinux therapy; an anti-Xa assay may be used instead. Also, test stools for occult blood, as ordered.
- Monitor patient with thrombocytopenia for evidence of thrombosis that may appear similar to heparin-induced thrombocytopenia even when no exposure to heparin has taken place. If patient's platelet count falls below  $100,000/\text{mm}^3$ , fondaparinux should be discontinued.
- Monitor renal function test results, as ordered. Expect to discontinue drug if labile renal function or severe renal impairment occurs during fondaparinux therapy because the risk of hemorrhage increases as renal function decreases.
- Store drug at a controlled room temperature.

## PATIENT TEACHING

- Inform patient that fondaparinux can't be taken orally.
- Instruct patient to seek immediate help if she experiences signs of thromboembolism, such as neurologic changes and severe shortness of breath.
- Inform patient about the increased risk of bleeding. Instruct her or family member to watch for and report abdominal or lower back pain, black stools, bleeding gums, bloody urine, or severe headaches.

- Teach patient or family member how to administer fondaparinux by subcutaneous injection at home, if needed. Instruct her not to expel air bubble from a prefilled syringe to avoid expelling some of the drug. Tell her to insert the entire needle into a skinfold held between thumb and forefinger, and remind her to alternate administration sites.
- Caution patient to minimize bruising, by not rubbing the injection site after giving the drug.
- Review safe handling and disposal of syringes and needles.
- Advise patient to have follow-up appointments and prescribed laboratory tests.
- Tell patient that fondaparinux may cause serious side effects and to report any persistent, severe, or unusual signs and symptoms to prescriber.

**WARNING** Know that if patient is receiving fondaparinux with epidural or spinal anesthesia or spinal puncture, patient must be watched closely for development of spinal hematoma, which may cause long-term or permanent paralysis. If evidence of neurologic impairment, such as changes in sensory or motor function, occurs, notify prescriber immediately, because urgent care is needed to minimize hematoma's effect. Risk of epidural or spinal hematoma during fondaparinux therapy is increased by concurrent use of other drugs that affect hemostasis, a history of traumatic or repeated epidural or spinal punctures, or a history of spinal deformity or spinal surgery. The risk is also increased with indwelling epidural catheters.

- Advise patient to alert prescriber about any new drugs being taken, including over-the-counter drugs and especially drugs that affect clotting such as aspirin or NSAIDs.

## formoterol fumarate

# Oxeze Turbuhaler (CAN), Perforomist

## Class and Category

*Pharmacologic class:* Selective beta<sub>2</sub>-adrenergic agonist

*Therapeutic class:* Bronchodilator

## Indications and Dosages

- *To prevent exercise-induced bronchospasm*

### **POWDER FOR ORAL INHALATION (OXEZE TURBUHALER)**

**Adults and children age 6 and over.** 6 or 12 mcg at least 15 min before exercise every 12 hr as needed. *Maximum:* 24 mcg daily (children) and 48 mcg daily (adults).

- *To provide long-term treatment of bronchospasm in patients with chronic obstructive pulmonary disease (COPD), including chronic bronchitis and emphysema*

### **POWDER FOR ORAL INHALATION (OXEZE TURBUHALER)**

**Adults.** 6 or 12 mcg every 12 hr through inhaler device, dosage increased, as needed. *Maximum:* 48 mcg daily.

### **SOLUTION FOR ORAL INHALATION (PERFOROMIST)**

**Adults.** 20 mcg twice daily by nebulization. *Maximum:* 40 mcg daily.

Route	Onset	Peak	Duration
Oral inhalation	1–3 min	Unknown	12 hr

## Mechanism of Action

Selectively attaches to  $\beta_2$  receptors on bronchial membranes, stimulating the intracellular enzyme adenylyl cyclase to convert adenosine triphosphate to cAMP. The resulting increase in the intracellular cAMP level inhibits histamine release, relaxes bronchial smooth-muscle cells, and stabilizes mast cells.

## Contraindications

Hypersensitivity to formoterol fumarate or its components, patients who also have asthma and are not taking an inhaled corticosteroid, treatment of asthma as monotherapy

## Interactions

### DRUGS

*adrenergics*: Possibly increased sympathetic effects of formoterol

*beta blockers*: Decreased effects of both beta blockers and formoterol

*corticosteroids, diuretics, xanthine derivatives*: Possibly increased hypokalemic effect of formoterol

*disopyramide, macrolides, MAO inhibitors, phenothiazines, procainamide, quinidine, tricyclic antidepressants*: Possibly prolonged QT interval, increasing risk of ventricular arrhythmias

# Adverse Reactions

**CNS:** Anxiety, dizziness, fatigue, fever, headache, insomnia, malaise, tremor

**CV:** Angina, **arrhythmias**, chest pain, hypertension, **hypotension**, palpitations, **prolonged QT interval**, tachycardia

**EENT:** Dry mouth, laryngeal irritation, **laryngeal spasm or swelling**, hoarseness, pharyngitis, rhinitis and tonsillitis (in children), sinusitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, gastroenteritis, indigestion (in children); nausea

**MS:** Back pain, leg cramps, muscle spasms

**RESP:** **Asthma exacerbation**, bronchitis, **bronchospasm**, cough, dyspnea, increased sputum production, **paradoxical bronchospasm**, upper respiratory tract infection

**SKIN:** Dermatitis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hypokalemia**, **metabolic acidosis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- It is not known if drug affects a pregnant woman or fetus during labor and delivery. However other beta-agonists may interfere with uterine contractility.
- Use of drug should be restricted to patients during labor and delivery only if benefits outweighs the risks.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that formoterol therapy should not be used in patients as monotherapy to treat asthma. If asthma is present, patient must be on an inhaled corticosteroid before receiving formoterol because of an increased risk of hospitalization and death. There does not appear to be an increased risk of death with use of formoterol in patients with COPD.

**WARNING** Be aware that formoterol therapy should not be initiated in patients with acutely deteriorating COPD, which may be a life-threatening condition, nor should it be administered for the relief of acute symptoms.

- Use caution when administering formoterol to patients with cardiovascular disorders such as aneurysm, arrhythmias, coronary insufficiency, hypertension, or pheochromocytoma; in patients with seizure disorders or thyrotoxicosis; and in patients who are unusually responsive to sympathomimetic amines.
- Expect inhaled, short-acting beta<sub>2</sub>-agonists taken by the patient on a regular basis to be discontinued and used only for symptomatic relief of acute respiratory symptoms when formoterol therapy is begun. If an inhaled, short-acting beta<sub>2</sub>-agonist has not been prescribed for symptomatic relief of acute respiratory symptoms, expect one to be prescribed.
- Administer formoterol dry powder or solution only by oral inhalation.
- Store drug in its original packaging, and open immediately before use.

- Give inhalation solution only by standard jet nebulizer and air compressor.
- Watch closely for paradoxical bronchospasm; if this occurs, discontinue formoterol immediately and notify prescriber.
- Notify prescriber of any significant increases in pulse rate or blood pressure or worsening of chronic conditions because formoterol may produce cardiovascular reactions, including angina, arrhythmias, hypertension or hypotension, palpitations, and tachycardia. Drug may have to be discontinued if such reactions occur.

## **PATIENT TEACHING**

- Advise patient, especially if she has a significant cardiac history, to inform prescriber of any other drugs she takes before beginning formoterol therapy to prevent harmful drug interactions.
- Instruct patient to use manufacturer's device for inhaling powder form of formoterol and not to use a spacer.
- Teach patient proper use of powdered formoterol delivery system. Emphasize that she should only inhale, not exhale, through device.
- For solution form, teach patient how to use, clean, and store nebulizer equipment. Tell her to leave the vial in its original foil pack until just before use.
- Instruct patient who currently uses inhaled or oral corticosteroids to continue using them, as prescribed, even if she feels better after starting formoterol.
- Caution patient not to increase formoterol dosage or frequency without consulting prescriber because she may need a rapid-acting bronchodilator and excessive use may result in an overdose.
- Urge patient to notify prescriber if her symptoms worsen, if formoterol becomes less effective, or if she needs more inhalations of short-acting beta<sub>2</sub>-agonist than usual. This may indicate that her asthma is worsening.
- Instruct patient to notify prescriber immediately if she experiences chest pain, nervousness, palpitations, rapid heart rate, or tremor while taking formoterol because dosage may have to be adjusted. Also, alert patient to stop drug and seek immediate emergency care if allergic reaction occurs, such as the presence of difficulty breathing or swallowing, hives, itching, rash, or swelling.
- Ensure that patient has been informed that long-acting beta agonists, such as formoterol, increase the risk of asthma-related death and should

not be used without a long-term asthma control drug prior to starting formoterol therapy.

## foscarnet sodium

### Foscavir

## Class and Category

*Pharmacologic class:* Pyrophosphate analogue

*Therapeutic class:* Antiviral

## Indications and Dosages

- *To treat cytomegalovirus (CMV) retinitis in patients with acquired immunodeficiency syndrome (AIDS)*

### I.V. INFUSION

**Adults.** *Initial:* 90 mg/kg given over 1.5 to 2 hr (not to exceed 1 mg/kg/min) every 12 hr or 60 mg/kg given over a minimum of 1 hr (not to exceed 1 mg/kg/min) every 8 hr for 2 to 3 wks, depending on clinical response.

*Maintenance:* 90 mg/kg/day to 120 mg/kg/day given over 2 hr (not to exceed 1 mg/kg/min).

- *To treat acyclovir-resistant mucocutaneous herpes simplex virus (HSV) infections in immunocompromised patients*

### I.V. INFUSION

**Adults.** 40 mg/kg given over a minimum of 1 hr (not to exceed 1 mg/kg/min) either every 8 or 12 hr for 2 to 3 wk or until healing has taken place.

**DOSAGE ADJUSTMENT** For patients with renal impairment, dosage calculated individually when creatinine clearance becomes 1.4 ml/min/kg or less.

## Mechanism of Action

Selectively inhibits the pyrophosphate binding site on virus-specific DNA polymerases, which inhibits herpes virus replication.

## Contraindications

Hypersensitivity to foscarnet sodium or its components

## Incompatibilities

Administer only with 5% dextrose solution or normal saline solution. Also, do not administer with any other drug or supplement concurrently via the same catheter, as a chemical or physical reaction may occur.

## Interactions

### DRUGS

*acyclovir, aminoglycosides, amphotericin B, cyclosporine, loop diuretics, methotrexate, pentamidine (intravenous), ritonavir, ritonavir and saquinavir, tacrolimus:* Increased risk of renal dysfunction

*class IA antiarrhythmics (procainamide, quinidine), class III antiarrhythmics (amiodarone, dofetilide, sotalol),*

*phenothiazines, selected fluoroquinolones and macrolides, tricyclic antidepressants*: Increased risk of QT prolongation and possible torsades de pointes

*pentamidine (intravenous) and other drugs known to influence serum calcium levels*: Possibly hypocalcemia

## **Adverse Reactions**

**CNS:** Abnormal coordination, aggressive reaction, agitation, amnesia, anxiety, aphasia, asthenia, ataxia, **coma**, confusion, dementia, depression, dizziness, EEG abnormalities, fatigue, fever, hallucination, headache, hypoesthesia, insomnia, malaise, **meningitis**, nervousness, neuropathy, paresthesia, rigors, **seizures including grand mal**, sensory disturbances, somnolence, **status epilepticus**, stupor, thirst, tremors

**CV:** **Cardiac arrest**, chest pain, nonacute ECG abnormalities (first-degree AV block, nonspecific ST-T segment changes, sinus tachycardia), edema, elevated gamma GT level, hypertension, **hypotension**, palpitations, **prolonged QT interval, torsades de pointes, thrombosis, ventricular arrhythmia**

**EENT:** Conjunctivitis, dry mouth, eye abnormalities or pain, pharyngitis, rhinitis, sinusitis, **stridor**, taste perversions, vision abnormalities, ulcerative stomatitis

**ENDO:** Diabetes insipidus (usually nephrogenic), syndrome of inappropriate antidiuretic hormone secretion

**GI:** Abdominal pain, abnormal A-G ratio, anorexia, cachexia, constipation, diarrhea, dyspepsia, dysphagia, elevated liver or pancreatic enzymes, esophageal ulceration, flatulence, **GI hemorrhage, hepatic**

**dysfunction, melena, nausea, pancreatitis, rectal hemorrhage, vomiting**

**GU: Acute renal failure, acquired Fanconi syndrome, albuminuria, crystal-induced nephropathy, decreased creatinine clearance, dysuria, elevated BUN or serum creatinine level, glomerulonephritis, hematuria, nephrotic syndrome, nephrotoxicity, nocturia, polyuria, renal calculus or impairment, renal tubular acidosis or necrosis, urethral disorder, urinary retention, UTI**

**HEME: Anemia, granulocytopenia, leukopenia, neutropenia, pancytopenia, thrombocytopenia**

**MS: Arthralgia, back pain, generalized spasms, involuntary muscle contractions, leg cramps, muscle weakness, myalgia, myositis, rhabdomyolysis**

**RESP: Bronchospasm, coughing, dyspnea, hemoptysis, pneumonia, pneumothorax, pulmonary infiltration, respiratory insufficiency**

**SKIN: Diaphoresis, erythema multiforme, erythematous or maculopapular rash, flushing, pruritus, rash, seborrhea, skin discoloration or ulceration, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria**

**Other: Acidosis, anaphylaxis, angioedema, dehydration, elevated alkaline phosphatase or LDH, flu-like symptoms, generalized pain, hypercalcemia, hypernatremia, hyperphosphatemia, hypocalcemia, hypokalemia, hypomagnesemia, hypophosphatemia, hypoproteinemia, infections (bacterial, fungal, moniliasis), injection-site inflammation or pain, localized edema, lymphadenopathy, lymphoma-like disorder, sarcoma, sepsis, weight loss**

## **Childbearing Considerations**

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## **Nursing Considerations**

- Know that foscarnet therapy should not be used in patients on a controlled sodium diet, because of the sodium content of the drug.
- Use cautiously in patients with history of prolonged QT interval, in patients taking drugs known to prolong the QT interval, in patients with electrolyte disturbances, or in patients who have other risk factors for QT prolongation, as QT prolongation and torsades de pointes have occurred with foscarnet therapy. Expect prescriber to order routine electrocardiograms and measure patient's electrolytes before foscarnet therapy is begun and periodically throughout therapy.
- Use foscarnet cautiously in patients with neurologic abnormalities (especially seizure disorders), and patients with decreased total calcium or other electrolyte abnormalities before treatment, as well as in patients receiving other drugs known to influence serum calcium levels.
- Assess patient's estimated or measured creatinine clearance before foscarnet therapy is begun, 2 to 3 times a week during initial therapy, and once weekly during maintenance therapy, as ordered, because most patients will experience some decrease in renal function as a result of foscarnet therapy. Know also that a 24-hour creatinine clearance should be determined before therapy is begun and periodically thereafter to ensure correct dosing. Expect foscarnet to be discontinued if creatinine clearance drops below 0.4 ml/min/kg.

- Determine patient's serum calcium, magnesium, phosphorus, and potassium levels before foscarnet therapy is begun, 2 to 3 times a week during initial therapy, and once weekly during maintenance therapy, as ordered, because foscarnet can chelate divalent metal ions and alter levels of serum electrolytes.
- Know that combination therapy with foscarnet and ganciclovir is indicated for patients who have relapsed after monotherapy with either drug used to treat CMV retinitis.
- Expect to calculate each dose, even in the presence of a normal serum creatinine, to reduce risk of nephrotoxicity. Know that the standard 24 mg/ml solution may be used with or without dilution when using a central venous catheter for infusion. If a peripheral vein catheter is used, the standard 24 mg/ml solution must be diluted to a 12 mg/ml concentration with 5% dextrose in water or normal saline solution prior to administration to avoid local irritation of peripheral veins. The diluted solution must be used within 24 hours.
- Maintain adequate hydration of patient to reduce the risk of nephrotoxicity. Expect to administer 750 to 1000 ml of 5% dextrose solution or normal saline prior to the first infusion of foscarnet to establish diuresis. With subsequent infusions, expect to infuse 750 to 1,000 ml of hydration fluid with a dose of 90 to 120 mg/kg of foscarnet and 500 ml of hydration fluid with a dose of 40 to 60 mg/kg. Oral hydration may be used instead if patient is able to drink the required amount of fluid.

**WARNING** Do not administer foscarnet by bolus or rapid intravenous injection, because toxicity increases with excessive plasma levels. An infusion pump must be used to control the rate of infusion. The rate of infusion should not exceed 1 mg/kg/min. Also know that foscarnet must be infused only in veins with adequate blood flow, because adverse reactions can occur. For example, irritation and ulcerations of penile epithelium have occurred in male patients and genital irritation and ulceration have occurred in female patients, possibly related to the presence of the drug in the urine. Ensure that patient has good personal hygiene as well as being adequately hydrated, which may minimize these effects.

- Flush eyes or skin with water if accidental contact with foscarnet occurs, because a burning sensation and local irritation may occur.
- Monitor patient for symptoms of electrolyte abnormalities (mild: perioral numbness or paresthesias; severe: seizures) regularly. If present, notify prescriber and expect serum electrolyte and mineral levels to be assessed as soon as possible and treatment initiated if abnormalities are revealed.
- Assess patient closely for hypersensitivity reactions to foscarnet. Serious acute hypersensitivity reactions have occurred in patients exposed to foscarnet. If present, notify prescriber immediately, expect foscarnet to be discontinued, and provide supportive care, as indicated and ordered.

## PATIENT TEACHING

- Advise patient that foscarnet is not a cure for either CMV retinitis or mucocutaneous acyclovir-resistant HSV infection.
- Tell patient that it is important to maintain hydration during foscarnet therapy.
- Inform patient that the major adverse reactions related to foscarnet therapy are electrolyte abnormalities, kidney dysfunction, and seizures. Stress importance of reporting any abnormal, persistent, severe, or unusual signs and symptoms to prescriber, as dosage may have to be adjusted or drug discontinued.

**WARNING** Advise patient to get immediate emergency medical treatment if she develops any signs of an allergic reaction, such as difficulty breathing, hives, or swelling of her face, lips, tongue, or throat.

- Instruct patient to notify prescriber at once if she experiences serious adverse reactions such as confusion, feeling short of breath, increased thirst, pounding heartbeats, swelling, urinating less than usual or not at all, weakness, or weight gain.
- Caution patient to avoid performing hazardous activities such as driving until the effects of the drug on her nervous system are known and have been resolved.
- Inform mothers that breastfeeding is not recommended during foscarnet therapy, to prevent potentially serious adverse events in the nursing infant.

- Encourage patient being treated for CMV retinitis to have regular ophthalmologic examinations.

## fosinopril sodium

### Class and Category

*Pharmacologic class:* Angiotensin converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive, vaso-dilator

### Indications and Dosages

- *To manage blood pressure, alone or with other antihypertensives*

#### **TABLETS**

**Adults.** *Initial:* 10 mg daily. *Maintenance:* 20 to 40 mg daily or in divided doses. *Maximum:* 80 mg daily.

**Children weighing more than 50 kg (110 lb).** 5 to 10 mg daily as monotherapy.

- *As adjunct to treat heart failure*

#### **TABLETS**

**Adults.** 10 mg daily. *Maintenance:* 20 to 40 mg daily.

*Maximum:* 40 mg daily.

***DOSAGE ADJUSTMENT*** Initial dosage reduced to 5 mg daily, if needed, for patients with heart failure who have moderate to severe renal failure or recent aggressive diuresis.

Route	Onset	Peak	Duration
P.O.	1 hr	2-6 hr	24 hr

## Mechanism of Action

May reduce blood pressure by affecting renin-angiotensin-aldosterone system. By inhibiting angiotensin-converting enzyme, fosinopril:

- prevents conversion of angiotensin I to angiotensin II, a potent vasoconstrictor that also stimulates the adrenal cortex to secrete aldosterone
- may inhibit renal and vascular production of angiotensin II
- decreases serum angiotensin II level and increases serum renin activity, which decreases aldosterone secretion, slightly increasing the serum potassium level and fluid loss
- decreases vascular tone and blood pressure
- inhibits aldosterone release, which reduces sodium and water reabsorption and increases their excretion, further reducing blood pressure.

## Contraindications

Hypersensitivity to fosinopril, other ACE inhibitors, or their components

## Interactions

### DRUGS

*antacids*: Impaired fosinopril absorption

*diuretics, other antihypertensives*: Possibly additive hypotension

*lithium*: Increased blood lithium level and risk of lithium toxicity

*potassium-sparing diuretics, potassium supplements:*

Increased risk of hyperkalemia

*sodium aurothiomalate:* Nitritoid reactions, including facial flushing, hypotension, nausea, and vomiting

## **FOODS**

*salt substitutes:* Increased risk of hyper-kalemia

## **Adverse Reactions**

**CNS:** Confusion, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, mood changes, sleep disturbance, syncope, tremor, vertigo, weakness

**CV:** **Angina**, **arrhythmias (including AV conduction disorders, bradycardia)**, and tachycardia), claudication, **hypotension**, **MI**, orthostatic hypotension, palpitations

**EENT:** Dry mouth, epistaxis, eye irritation, hoarseness, rhinitis, sinus problems, taste perversion, tinnitus, vision changes

**GI:** Abdominal distention and pain, anorexia, constipation, diarrhea, flatulence, **hepatic failure**, **hepatitis**, hepatomegaly, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Decreased libido, flank pain, **renal insufficiency**, sexual dysfunction, urinary frequency

**MS:** Arthralgia, gout, myalgia

**RESP:** **Asthma**; bronchitis; **bronchospasm**; dry, persistent, tickling cough; dyspnea; tracheobronchitis; upper respiratory tract infection

**SKIN:** Diaphoresis, photosensitivity, pruritus, rash, urticaria

**Other:** Anaphylaxis, angioedema, hyperkalemia, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm during second and third trimester. Anuria, hypotension, neonatal skull hypoplasia, oligohydramnios, and reversible and irreversible renal failure have occurred along with fetal demise.
- Drug should be discontinued as soon as pregnancy is known.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Monitor serum potassium level before and during fosinopril therapy, as appropriate.
- Observe patient being treated for heart failure for at least 2 hours after giving drug to detect hypotension or orthostatic hypotension. If either develops, notify prescriber and monitor patient until blood pressure stabilizes. Keep in mind that orthostatic hypotension is unlikely to develop in patients with a systolic blood pressure over 100 mm Hg who receive a 10-mg dose.
- Separate administration times between antacids and fosinopril by at least 2 hours.
- Know that if patient also receives a diuretic or another antihypertensive, you should expect to reduce its dosage over 2 to 3 days before starting fosinopril. If blood pressure isn't controlled with fosinopril alone, other antihypertensive therapy may resume, as prescribed. If so, observe for excessive hypotension.

**WARNING** Know that if angioedema affects the face, glottis, larynx, limbs, lips, mucous membranes, or tongue, prescriber must be notified immediately. Expect to discontinue fosinopril and start appropriate therapy at once. If airway obstruction threatens, promptly give 0.3 to 0.5 ml of epinephrine solution 1:1,000 subcutaneously, as prescribed.

## **PATIENT TEACHING**

- Instruct patient to take fosinopril at same time each day to improve compliance and maintain drug's therapeutic effect.
- Emphasize the importance of taking fosinopril as prescribed, even if patient feels well. Caution her not to stop taking drug without consulting prescriber.
- Explain that drug helps control—but doesn't cure—hypertension and that patient may need lifelong therapy.

**WARNING** Urge patient to seek immediate medical attention for difficulty breathing or swallowing, hoarseness, or swelling of the face, lips, throat, or tongue.

- Instruct patient to notify prescriber about persistent, severe diarrhea, nausea, and vomiting; resulting dehydration may lead to hypotension.
- Advise patient not to take other drugs or use salt substitutes without consulting prescriber.
- Encourage patient to keep scheduled appointments with prescriber to monitor blood pressure, blood test results, and effects of therapy.
- Caution patient about possible dizziness.
- Advise patient to rise slowly from a lying or sitting position and to dangle legs over bed for several minutes before standing to minimize effects of orthostatic hypotension.
- Reinforce prescriber's recommendations for lifestyle changes, such as alcohol avoidance, dietary improvements, smoking cessation, regular exercise, and stress reduction.

- Urge women of childbearing age to use contraception during therapy because drug may harm fetus.
- Advise patient to use caution during exercise and hot weather because of the increased risk of dehydration from excessive sweating.

## fosphenytoin sodium

**Cerebyx**

### Class and Category

*Pharmacologic class:* Hydantoin derivative

*Therapeutic class:* Anticonvulsant

### Indications and Dosages

➤ *To treat generalized tonic-clonic status epilepticus*

#### I.V. INFUSION, I.M. INJECTION

**Adults.** *Emergent loading dose (Status epilepticus):* 15 to 20 mg of phenytoin equivalent (PE)/kg I.V. at 100 to 150 PE/min *Nonemergent loading dose:* 10 to 20 PE/min I.V. given at 100 to 150 PE/min. *Maintenance:* 4 to 6 mg PE/kg daily in divided doses I.V. at a rate no greater than 150 mg PE/min or I.M.

#### I.V. INFUSION

**Neonates, infants, children, and adolescents to age 17 years.** *Emergent loading dose (Status epilepticus):* 15 to 20 mg PE/kg I.V. at a rate of 2 mg PE/kg/min or 150 mg

PE/min for I.V. administration, whichever is slower.

*Nonemergent loading dose:* 10 to 15 mg PE/kg at a rate of 1 to 2 mg PE/kg/min or 150 mg PE/min, whichever is slower. *Maintenance:* 2 to 4 mg PE/kg given 12 hr after loading dose and then continued every 12 hr at a rate of 1 to 2 mg PE/kg/min or 100 mg PE/min, whichever is slower.

➤ *To prevent or treat seizures during neurosurgery*

## **I.V. INFUSION, I.M. INJECTION**

**Adults.** *Loading:* 10 to 20 mg PE/kg, not to exceed 150 mg PE/min for I.V. administration. *Maintenance:* 4 to 6 mg PE/kg in divided doses.

## **I.V. INFUSION**

**Neonates, infants, children, and adolescents to age 17 years.** *Loading:* 10 to 15 mg PE/kg at a rate of 1 to 2 mg PE/kg/min or 150 mg PE/min, whichever is slower. *Maintenance:* 2 to 4 mg PE/kg given 12 hr after initial dose and then continued every 12 hr at a rate of 1 to 2 mg PE/kg/min or 100 mg PE/min, whichever is slower.

➤ *To substitute for oral phenytoin therapy when administration of oral phenytoin is not possible.*

## **I.V. INFUSION, I.M. INJECTION**

**Adults.** Same total daily phenytoin sodium equivalents (PE) dose. I.V. infusion rate should not exceed 150 mg PE/min.

## **Mechanism of Action**

Is converted from fosphenytoin (a prodrug) to phenytoin, which limits the spread of seizure activity and the start of new seizures. Phenytoin does so by regulating voltage-

dependent sodium and calcium channels in neurons, inhibiting calcium movement across neuronal membranes, and enhancing the sodium-potassium-adenosine triphosphatase activity in neurons and glial cells. These actions may stem from phenytoin's ability to slow the recovery rate of inactivated sodium channels.

## Contraindications

Adams-Stokes syndrome, concurrent delavirdine use; history of prior acute hepatotoxicity caused by fosphenytoin or phenytoin; hypersensitivity to fosphenytoin, phenytoin, other hydantoins, or their components; second- or third-degree A-V block; sino-atrial block; sinus bradycardia

## Interactions

### DRUGS

*acyclovir*: Decreased blood phenytoin level, loss of seizure control

*alfentanil*: Increased clearance and decreased effectiveness of alfentanil  
*albendazole*, *antiepileptics* (*carbamazepine*, *felbamate*, *lamotrigine*, *topiramate*, *oxcarbazepine*), *antilipidemics* (*atorvastatin*, *fluvastatin*, *simvastatin*), *antivirals* (*efavirenz*, *lopinavir/ritonavir*, *indinavir*, *nelfinavir*, *ritonavir*, *saquinavir*), *calcium channel blockers* (*nifedipine*, *nimodipine*, *verapamil*), *chlorpromazine*, *clozapine*, *cyclosporine*, *digoxin*, *disopyramide*, *folic acid*, *methadone*, *mexiletine*, *praziquantel*, *quetiapine*:

Decreased blood levels of these drugs

*amiodarone*, *calcium channel blockers*, *capecitabine*, *chloramphenicol*, *chlorthalidone*, *cimetidine*, *disulfiram*, *estrogen*, *ethosuximide*, *felbamate*, *fluconazole*, *fluorouracil*, *fluoxetine*, *fluvastatin*, *fluvoxamine*, *isoniazid*,

*itraconazole, ketoconazole, methylphenidate, miconazole, omeprazole, oxcarbazepine, phenothiazines, salicylates, sertraline, sulfadiazine, sulfamethizole, sulfamethoxazole-trimethoprim, sulfaphenazole, ticlopidine, tolbutamide, topiramate, trimethoprim, voriconazole, warfarin:* Possibly increased blood phenytoin level and risk of toxicity  
*antineoplastics, carbamazepine, diazepam, diazoxide, folic acid, fosamprenavir, nelfinavir, reserpine, rifampin, ritonavir, St. John's wort, theophylline, vigabatrin:* Increased phenytoin metabolism and decreased phenytoin level

*antineoplastic agents (irinotecan, paclitaxel, teniposide), azoles (fluconazole, ketoconazole, itraconazole, posaconazole, voriconazole), corticosteroids, delavirdine, doxycycline, estrogens, furosemide, neuromuscular blocking agents (cisatracurium, pancuronium, rocuronium, vecuronium), oral contraceptives, paroxetine, quinidine, rifampin, sertraline, theophylline, vitamin D, warfarin:* Decreased effectiveness of these drugs  
*lithium:* Increased risk of lithium toxicity  
*methadone:* Possibly increased methadone  
*phenobarbital, valproate sodium, valproic acid:* Possible decrease or increase in phenytoin serum levels  
*tricyclic antidepressants:* Possibly lowered seizure threshold and decreased therapeutic effects of phenytoin; possibly decreased blood antidepressant level  
*valproic acid:* Increased blood valproic acid level

## **ACTIVITIES**

*alcohol use:* Possibly decreased or increased phenytoin effectiveness

## **Adverse Reactions**

**CNS:** Agitation, amnesia, asthenia, ataxia, **cerebral edema**, chills, **coma**, confusion, **CVA**, decreased or increased reflexes, delusions, depression, dizziness, dyskinesia, emotional lability, **encephalitis**, **encephalopathy**, extrapyramidal reactions, fever, headache, hemiplegia, hostility, hypoesthesia, lack of coordination, malaise, **meningitis**, nervousness, neurosis, paralysis, paresthesia, personality disorder, positive Babinski's sign, **seizures**, somnolence, speech disorders, stupor, **subdural hematoma**, syncope, transient paresthesia, tremor, vertigo

**CV:** **Atrial flutter**, **bradycardia**, bundle-branch block, **cardiac arrest**, **cardiomegaly**, edema, **heart failure**, hypertension, **hypotension**, orthostatic hypotension, palpitations, **PVCs**, **serious arrhythmias**, **shock**, tachycardia, thrombophlebitis, vasodilation

**EENT:** Amblyopia, conjunctivitis, diplopia, dry mouth, earache, epistaxis, eye pain, gingival hyperplasia, hearing loss, hyperacusis, increased salivation, loss of taste, mydriasis, nystagmus, pharyngitis, photophobia, rhinitis, sinusitis, taste perversion, tinnitus, tongue swelling, visual field defects

**ENDO:** Decreased dexamethasone, metyrapone, or T4 levels; diabetes insipidus; hyperglycemia; **ketosis**

**GI:** Anorexia, constipation, diarrhea, dysphagia, elevated liver enzymes, flatulence, gastritis, **GI bleeding**, **hepatic necrosis**, **hepatitis**, ileus, indigestion, nausea, vomiting

**GU:** Albuminuria, dysuria, incontinence, oliguria, polyuria, **renal failure**, urine retention, vaginal candidiasis

**HEME:** **Agranulocytosis**, anemia, easy bruising, **granulocytopenia**, **leukopenia**, lymphadenopathy, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, back or pelvic pain, dysarthria, leg cramps, muscle twitching, myalgia, myasthenia, myoclonus, myopathy

**RESP:** **Apnea**, **asthma**, **atelectasis**, bronchitis, dyspnea, **hemoptysis**, hyperventilation, **hypoxia**, increased cough, increased sputum production, pneumonia, **pneumothorax**

**SKIN:** **Acute generalized exanthematous pustulosis (AGEP)**, contact dermatitis, diaphoresis, maculopapular or pustular rash, photosensitivity, pruritus, skin discoloration, skin nodule, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**; **angioedema**; cachexia; **cryptococcosis**; dehydration; **drug reaction with eosinophilia and systemic symptoms (DRESS)**; elevated alkaline phosphatase; flu-like symptoms; **hyperkalemia**; **hypokalemia**; **hypophosphatemia**; infection; injection-site reaction such as edema, discoloration, and pain distal to the site of injection; lymphadenopathy; porphyria; **sepsis**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Drug may cause fetal harm increasing risk for congenital malformations and other adverse developmental outcomes, including hydantoin syndrome. In addition, malignancies, including neuroblastoma have been reported in children whose mothers received drug during pregnancy.
- A potentially life-threatening bleeding disorder may occur in neonates exposed to drug in utero.
- Drug is not recommended in pregnancy unless absolutely necessary and no other alternative is available.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Women of childbearing age should use effective contraception throughout drug therapy.

## Nursing Considerations

- Be aware that the dosage, concentration, and infusion rate of fosphenytoin are expressed in PE units. Misreading an order or a label could result in massive overdose.
- Refrigerate unopened fosphenytoin at 2° to 8° C (36° to 46° F), but don't freeze.
- Dilute drug in D<sub>5</sub>W or normal saline solution to 1.5 to 25 mg PE/ml.
- Inspect parenteral solution before administration. Discard solution that contains particles or is discolored.
- Be aware that drug shouldn't be given I.M. for status epilepticus because I.V. route allows faster onset and peak.
- Keep in mind that I.V. fosphenytoin administration doesn't require use of a filter, as with phenytoin administration.
- Don't give fosphenytoin solution faster than 150 mg PE/minute because of the risk of cardiac arrhythmias and severe hypotension. For a 50-kg (110-lb) patient, infusion typically takes 5 to 7 minutes. Monitor patient throughout the infusion for adverse signs and symptoms of cardiovascular toxicity. If present, notify prescriber and expect infusion rate to be slowed or drug discontinued.
- Monitor patient for signs of sensory disturbances during the infusion, such as severe burning, itching, and/or paresthesia. Know that the intensity of discomfort can be lessened by slowing or temporarily stopping the infusion.
- Follow loading dose with maintenance dosage of oral or parenteral phenytoin or parenteral fosphenytoin, as prescribed.

- Give an I.V. benzodiazepine (such as diazepam or lorazepam) as prescribed with fosphenytoin; otherwise, drug's full antiepileptic effect won't be immediate.
- Monitor blood pressure, ECG, and respiratory function for 10 to 20 minutes after infusion ends.
- Expect to obtain blood fosphenytoin (phenytoin) level 2 hours after I.V. infusion or 4 hours after I.M. injection. Therapeutic level generally ranges from 10 to 20 mcg/ml; steady-state may take several days to several weeks to reach.
- Be aware that I.V. or I.M. fosphenytoin may be substituted for oral phenytoin sodium at same total daily dose and frequency. If prescribed, give daily amount in two or more divided doses to maintain seizure control.
- Know that antiepileptic drugs such as fosphenytoin should not be discontinued abruptly, because of the possibility of increased seizure frequency, including status epilepticus.
- Remember that when switching between phenytoin and fosphenytoin, small differences in phenytoin bioavailability can lead to significant changes in blood phenytoin level and an increased risk of toxicity.
- Monitor CBC for leukopenia or thrombocytopenia—signs of hematologic toxicity. Also monitor serum albumin level and results of liver and renal function tests.
- Anticipate increased frequency and severity of adverse reactions after I.V. administration in patients with hepatic or renal impairment or hypoalbuminemia. Know that the phosphate load contained in fosphenytoin should be kept in mind when patients with severe renal impairment who require phosphate restriction are treated.

**WARNING** Discontinue drug, as ordered, if signs of hypersensitivity develop: acute hepatotoxicity (hepatic necrosis and hepatitis), fever, lymphadenopathy, and skin reactions during first 2 months of therapy. Expect to rapidly substitute drug with alternative therapy not belonging to the hydantoin chemical class because abrupt withdrawal of fosphenytoin may increase risk of seizures, including status epilepticus.

- Monitor phenytoin level to detect early signs of toxicity, such as diplopia, nausea, severe confusion, slurred speech, and vomiting. Expect to reduce or stop drug.

**WARNING** Monitor patient for seizures; at toxic levels, phenytoin is excitatory.

**WARNING** Know that if patient has bradycardia or heart block rhythm, you must notify prescriber and expect to withhold drug; severe cardiovascular reactions and death have occurred.

- Expect to provide vitamin D supplement if patient has inadequate dietary intake and is receiving long-term anticonvulsant treatment.
- Document onset, characteristics, and type of seizures and response to treatment.
- Monitor patient for injection-site reactions such as local toxicity known as Purple Glove syndrome, exhibited by discoloration, edema, and pain distal to the site of injection. Know that this may occur without extravasation being present and up to several days after injection. If present, notify prescriber and expect drug to be discontinued.

**WARNING** Know that patients of Asian ancestry who have the genetic allelic variant HLA-B 1502 develop serious and sometimes fatal dermatologic reactions 10 times more often than people without this variant when given carbamazepine, another antiepileptic drug. Because early data suggest a similar effect with fosphenytoin, this drug shouldn't be used as a substitute for carbamazepine in these patients.

- Monitor all patients' skin for skin reactions, because serious and sometimes fatal dermatologic reactions may occur, usually within the first 28 days of treatment. Notify prescriber at the first sign of a rash or other skin abnormalities.

## **PATIENT TEACHING**

- Inform patient that fosphenytoin typically is used for short-term treatment.

**WARNING** Urge patient to seek immediate medical care if allergic reactions occur, especially swelling of face, lips, or upper airway making breathing difficult.

- Inform patient that some sensory discomfort may be felt during fosphenytoin administration. Advise patient to alert the nurse, as slowing the infusion can decrease the discomfort.
- Instruct patient to notify prescriber immediately about bothersome symptoms, especially rash and swollen glands or local reaction at injection site, including discoloration, edema, and pain distal to the site, and swelling. Also notify prescriber immediately if persistent, severe, or unusual signs and symptoms occur as well as a skin rash.
- Tell patient to inform prescriber of all drugs being used, including over-the-counter preparations and alcohol products, before using.
- Emphasize need for good oral hygiene and gum massage because gingival hyperplasia may develop during long-term therapy when oral phenytoin therapy is not feasible.
- Urge patient to consume adequate amounts of vitamin D.
- Warn women of childbearing age that fosphenytoin may cause congenital malformations and developmental issues in the fetus. Advise female patient to use effective contraceptive and to notify prescriber immediately if pregnancy is suspected or occurs.

**fremanezumab-vfrm**

**Ajovy**

## **Class and Category**

*Pharmacologic class:* Calcitonin gene-related peptide antagonist

*Therapeutic class:* Antimigraine

## Indications and Dosages

➤ *To prevent migraine headaches*

### SUBCUTANEOUS INJECTION

**Adults.** 225 mg monthly. Alternatively, 675 mg every 3 months given as 3 consecutive injections of 225 mg each.

Route	Onset	Peak	Duration
SQ	Unknown	5 to 7 days	Unknown

## Mechanism of Action

Binds to the calcitonin gene-related peptide (CGRP) receptor. The CGRP receptor is thought to be responsible for transmitting signals that can cause incapacitating pain. By binding to the CGRP receptor, drug antagonizes its function, preventing pain signals from being transmitted.

## Contraindications

Hypersensitivity to fremanezumab-vfrm or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**SKIN:** Pruritus, rash, urticaria

**Other:** Fremanezumab-vfrm antibody formation, injection-site reactions (induration, pain, redness)

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that women with migraine may be at increased risk of preeclampsia during pregnancy.

### **LACTATION**

- It is not known if drug maybe present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Remove fremanezumab-vfrm from refrigerator and allow it to sit at room temperature for 30 minutes protected from direct sunlight prior to administration. Do not warm drug using a heat source such as hot water or a microwave. Discard if drug has been left at room temperature for 24 hours or longer.
- Inspect solution for discoloration or particles. Do not use if solution appears to be cloudy, discolored, or contains particles.
- Administer subcutaneously into the abdomen, thigh, or upper arm in an area that is not bruised, indurated, red, or tender. If giving 3 consecutive injections, the same body site may be used, but not the exact location of the previous injection. Do not coadminister drug with other injectable drugs at the same injection site.
- Monitor patient for an allergic reaction such as hives, itching, or a rash. Be aware that most allergic reactions occur within hours to 1 month after administration. Know that if an allergic reaction occurs, the drug may have to be discontinued and signs and symptoms treated.

- Know that when switching dosage options, the first dose of the new regimen should be administered on the next scheduled date of administration.

## PATIENT TEACHING

- Tell patient that if a dose is missed, she should administer it as soon as she remembers. Thereafter, the next dose can be scheduled from the date of that dose.
- Teach patient how to prepare and administer drug subcutaneously, if self-injecting.
- Instruct patient to remove fremanezumab-vfrm from refrigerator and allow it to sit at room temperature for 30 minutes protected from direct sunlight prior to administration. Warn patient not to warm drug using a heat source such as hot water or a microwave. Tell patient to discard drug if it has been left at room temperature for 24 hours or longer.
- Tell patient to inspect solution for discoloration or particles and not to use if solution appears to be cloudy, discolored, or contains particles.
- Instruct patient to administer fremanezumab-vfrm subcutaneously into the abdomen, thigh, or upper arm in an area that is not bruised, indurated, red, or tender. If giving 3 consecutive injections, tell patient that the same body site may be used, but not the exact location of the previous injection. Warn patient not to coadminister drug with other injectable drugs at the same injection site.
- Inform patient that when switching dosage options, first dose of the new regimen should be administered on the next scheduled date of administration.
- Advise patient that drug may cause an allergic reaction within hours to up to 1 month following administration. If hives, itching, or a rash occurs, tell patient to notify prescriber immediately, because drug may have to be discontinued and the allergic reaction may require additional treatment.

**frovatriptan succinate**

**Frova**

## Class and Category

*Pharmacologic class:* Serotonin 5-HT<sub>1</sub> receptor agonist

*Therapeutic class:* Antimigraine

## Indications and Dosages

➤ *To treat acute migraine headache*

### **TABLETS**

**Adults.** 2.5 mg, as needed. If migraine returns, 2.5-mg dose repeated providing there is at least a 2-hr interval between the 2 doses. *Maximum:* 7.5 mg (3 2.5-mg doses) per 24 hr.

## Mechanism of Action

Binds to 5-HT<sub>1</sub> receptors on intracranial blood vessels and sensory nerves of the trigeminal system to produce cranial vessel constriction and inhibition of proinflammatory neuropeptide release, which causes pain relief.

## Contraindications

Arrhythmias associated with cardiac accessory conduction pathway disorders such as Wolff-Parkinson-White syndrome; history of basilar or hemiplegic migraine, stroke, or transient ischemic attack; hypersensitivity to frovatriptan or its components; ischemic coronary artery disease or coronary artery vasospasm; ischemic bowel disease; peripheral vascular disease; uncontrolled hypertension; use within 24 hours of another 5-HT<sub>1</sub> agonist or an ergotamine-containing or ergot-type drug such as dihydroergotamine or methysergide

# Interactions

## DRUGS

*ergot-containing or ergot-type drugs such as dihydroergotamine, methysergide*: Increased risk of prolonged vasospastic reaction

*MAO inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, tricyclic antidepressants*: Possible development of serotonin syndrome

*other 5-HT<sub>1</sub> agonists*: Potential additive effects increasing risk of serious adverse reactions

## Adverse Reactions

**CNS:** Anxiety; **cerebral hemorrhage, CVA, and other cerebrovascular events**; dizziness; dysesthesia; exacerbation of headache; fatigue; hypoesthesia; insomnia; palpitations; paresthesia; **seizure; serotonin syndrome; subarachnoid hemorrhage**

**CV:** **Arrhythmias, including ventricular fibrillation or tachycardia**; chest, jaw, neck, or throat pain, pressure, or tightness; **MI; myocardial ischemia**; peripheral vascular ischemia; Prinzmetal's angina; Raynaud's syndrome

**EENT:** Abnormal vision, blindness (transient or permanent), dry mouth, partial vision loss, rhinitis, sinusitis, tinnitus

**GI:** Abdominal pain, bloody diarrhea, diarrhea, dyspepsia, **gastrointestinal vascular infarction or ischemia**, splenic infarction, vomiting

**RESP:** Bone pain

**SKIN:** Diaphoresis, flushing

**Other:** **Anaphylaxis**, **angioedema**, generalized pain, sensation of being cold or hot

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that women with migraine may be at increased risk of preeclampsia during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect triptan-naïve patient with multiple cardiovascular risk factors such as diabetes, increased age, hypertension, obesity, smoking, or strong family history of coronary artery disease to have a cardiovascular evaluation prior to frovatriptan being prescribed, because drug can cause serious cardiovascular disorders such as myocardial infarction or ischemia and Prinzmetal's angina. In patients who have a negative cardiovascular evaluation, know that the first dose of frovatriptan may be administered in a medically supervised setting with an EKG performed immediately following administration to detect adverse effects. Expect periodic cardiovascular evaluations to be performed throughout frovatriptan therapy. Also expect drug to be immediately discontinued if patient develops arrhythmias, because of potential life-threatening consequences.
- Know that if patient complains of chest, jaw, neck, or throat pain, pressure, or tightness, an immediate cardiovascular evaluation should be performed even though these symptoms are usually noncardiac in nature.

- Monitor patient for signs and symptoms of cerebrovascular events, because drug use increases risk of CVAs and cerebrovascular hemorrhage.
- Monitor patient for noncardiovascular vasospasm events such as gastrointestinal vascular infarction and ischemia (abdominal pain, bloody diarrhea), peripheral vascular ischemia, Raynaud's syndrome, or splenic infarction. If suspected, notify prescriber immediately, stop frovatriptan therapy, and be prepared to provide emergency supportive care according to institutional protocol.

**WARNING** Monitor patient for evidence of serotonin syndrome, such as agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. Be aware that risk is greater during coadministration with monoamine oxidase inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, and tricyclic antidepressants. Onset of symptoms usually occurs within minutes to hours of receiving a new or a greater dose of a serotonergic medication. If serotonin syndrome is suspected, notify prescriber immediately, expect drug to be discontinued, and provide symptomatic supportive care, as prescribed.

- Monitor patient's blood pressure, because significant elevation in blood pressure, including hypertensive crisis, has been reported in patients treated with other 5-HT<sub>1</sub> agonists.

**WARNING** Monitor patient for hypersensitivity reactions to frovatriptan. These reactions may be life-threatening and include anaphylaxis and angioedema. Stop drug therapy immediately and notify prescriber if a hypersensitivity reaction occurs. Provide supportive care, as prescribed.

## **PATIENT TEACHING**

- Tell patient to take drug exactly as prescribed and not to overuse drug by using it 10 days or more in a month, because medication-overuse headache may develop. If patient begins to experience daily migraine-like headaches or a marked increase in frequency of headaches, tell him to notify prescriber. Inform him that a period of detoxification may be necessary.

**WARNING** Alert patient that frovatriptan therapy may cause allergic reactions that may become severe. Tell patient to notify prescriber at the first sign of an allergic reaction and to seek immediate medical attention if difficulty breathing, or swelling, especially of eyes, face, or throat, occurs.

- Advise patient to notify all prescribers of frovatriptan therapy, because serious drug interactions can occur with certain medications when taken concomitantly with frovatriptan.
- Tell women of childbearing age that drug should not be used during pregnancy. If pregnancy occurs or is suspected, tell patient to notify prescriber.

**WARNING** Inform patient that drug has the potential to cause a heart attack or stroke or other forms of vasospastic disorders. Instruct patient to seek immediate emergency treatment if he experiences chest pain, shortness of breath, slurring of speech, or weakness, or if he develops persistent, severe, or unusual signs and symptoms.

## furosemide

**Furoside (CAN), Lasix, Lasix Special (CAN)**

# Class and Category

*Pharmacologic class:* Loop diuretic

*Therapeutic class:* Antihypertensive, diuretic

## Indications and Dosages

- *To reduce edema caused by cirrhosis, heart failure, and renal disease, including nephrotic syndrome*

### ORAL SOLUTION, TABLETS

**Adults.** 20 to 80 mg as a single dose, increased by 20 to 40 mg every 6 to 8 hr until desired response occurs.

*Maintenance:* Effective dose given once or divided and given twice daily (8am and 2 pm). *Maximum:* 600 mg daily.

**Children.** 2 mg/kg as a single dose, increased by 1 to 2 mg/kg every 6 to 8 hr until desired response occurs.  
*Maximum:* 6 mg/kg/dose.

### I.V. INFUSION, I.V. OR I.M. INJECTION

**Adults.** 20 to 40 mg as a single dose, increased by 20 mg every 2 hr until desired response occurs. I.V. injection given slowly over 1 to 2 min. I.V. infusion given at a rate of not greater than 4 mg/min.

### I.V. INJECTION

**Adults with pulmonary edema.** 40 mg given slowly over 1 to 2 min with dosage repeated but increased to 80 mg after 1 hr, as needed.

### I.V. OR I.M INJECTION

**Children.** 1 mg/kg as a single dose, increased by 1 mg/kg every 2 hr until desired response occurs. *Maximum:* 6

mg/kg/dose, (children), 1 mg/kg/day (premature infants).

➤ *To manage hypertension*

**DOSAGE ADJUSTMENT** Initial single dose limited to 20 mg for elderly patients.

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 40 mg twice daily, adjusted until desired response occurs.

Route	Onset	Peak	Duration
P.O.	20-60 min	1-2 hr	6-8 hr
I.V.	5 min	In 30 min	2 hr
I.M.	30 min	Unknown	2 hr

## Mechanism of Action

Inhibits sodium and water reabsorption in the loop of Henle and increases urine formation. As the body's plasma volume decreases, aldosterone production increases, which promotes sodium reabsorption and the loss of potassium and hydrogen ions. Furosemide also increases the excretion of calcium, magnesium, bicarbonate, ammonium, and phosphate. By reducing intracellular and extracellular fluid volume, the drug reduces blood pressure and decreases cardiac output. Over time, cardiac output returns to normal.

## Incompatibilities

Don't mix furosemide (a milky, buffered alkaline solution) with highly acidic solutions.

## Contraindications

Anuria, hypersensitivity to furosemide or its components

## Interactions

### DRUGS

*ACE inhibitors, angiotensin II receptor blockers:* Possibly first-dose hypotension, severe hypotension, deterioration in renal function

*aminoglycosides, cisplatin, ethacrynic acid:* Increased risk of ototoxicity

*cephalosporins:* Increased risk of cephalosporin-induced nephrotoxicity

*chloral hydrate:* Possibly diaphoresis, hot flashes, and hypertension

*cyclosporine:* Increased risk of gouty arthritis

*ganglionic or peripheral adrenergic blocking agents:* Increased furosemide effects

*indomethacin:* Possibly reduced natriuretic and antihypertensive effects of furosemide

*lithium:* Increased risk of lithium toxicity

*methotrexate and other drugs that undergo significant renal tubular secretion:* Possibly decreased therapeutic effects of furosemide

*norepinephrine:* Possibly decreased arterial response to norepinephrine

*NSAIDs:* Possibly increased BUN, serum creatinine and serum potassium levels; weight gain

*phenytoin:* Possibly decreased therapeutic effects of furosemide

*succinylcholine:* Increased action of succinylcholine

*sucralfate:* Possibly reduced natriuretic and antihypertensive effects of furosemide

*thiazide diuretics:* Possibly profound diuresis and electrolyte imbalances

*thyroid hormones*: Possibly overall decrease in total thyroid hormone levels with high doses (greater than 80 mg) of furosemide

*tubocurarine*: Antagonized skeletal muscle relaxing effect of tubocurarine

## Adverse Reactions

**CNS**: Dizziness, drowsiness, fever, headache, lethargy, paresthesia, restlessness, vertigo, weakness

**CV**: **Arrhythmias**, elevated cholesterol and triglyceride levels, orthostatic hypotension, shock, tachycardia, **thromboembolism**, thrombophlebitis vertigo

**EENT**: Blurred vision, deafness, dry mouth, oral irritation, ototoxicity, stomatitis, tinnitus, hearing loss (rapid I.V. injection), yellow vision

**ENDO**: Hyperglycemia

**GI**: Abdominal cramps, anorexia, constipation, diarrhea, elevated liver enzymes, gastric irritation, **hepatocellular insufficiency**, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU**: **Azotemia**, bladder spasms, glycosuria, oliguria

**HEME**: **Agranulocytosis** (rare), anemia, **aplastic anemia (rare)**, eosinophilia, **hemolytic anemia**, **leukopenia**, **thrombocytopenia**

**MS**: Muscle pain or spasms

**SKIN**: Acute generalized exanthematous pustulosis, bullous pemphigoid, **erythema multiforme**, **exfoliative dermatitis**, photosensitivity, pruritus, purpura, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** Allergic reaction, anaphylaxis, dehydration, drug reaction with eosinophilia and systemic symptoms (DRESS), hyperuricemia, hypocalcemia, hypochloremia, hypokalemia, hypomagnesemia, hyponatremia, hypovolemia, thirst

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- If drug is used during pregnancy, fetal growth should be monitored.

### LACTATION

- Drug is present in breast milk and as a diuretic partially inhibits lactation.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Use furosemide cautiously in patients with advanced hepatic cirrhosis, especially those who also have a history of electrolyte imbalance or hepatic encephalopathy; drug may lead to lethal hepatic coma.

- Be aware that patients who are allergic to sulfonamides may also be allergic to furosemide. Monitor patient closely.
- Know that furosemide may precipitate nephrocalcinosis/nephrolithiasis in premature infants. Know that in patients with nephrotic syndrome who are hypoproteinemic, furosemide therapy may be less effective and its ototoxicity potentiated. Drug may also increase the risk of persistence of patent ductus arteriosus in premature infants.

- Obtain patient's weight before and periodically during furosemide therapy to monitor fluid loss.
- Know that for once-a-day dosing, drug should be given in the morning so patient's sleep won't be interrupted by increased need to urinate.
- Prepare drug for infusion with normal saline solution, lactated Ringer's solution, or D<sub>5</sub>W.
- Administer drug slowly I.V. over 1 to 2 minutes to prevent ototoxicity. The risk of ototoxicity is also increased in patients who receive higher than recommended doses or who have hypoproteinemia or severe renal impairment. If high doses are prescribed, recheck with prescriber and expect to use an infusion pump so the infusion rate is no higher than 4 mg of furosemide per minute. Concomitant therapy with aminoglycoside antibiotics, ethacrynic acid, or other ototoxic drugs increases risk of ototoxicity as well.
- Expect patient to have periodic hearing tests during prolonged or high-dose I.V. therapy.
- Monitor blood pressure and hepatic and renal function as well as BUN, blood glucose, and serum creatinine, electrolyte, and uric acid levels, as appropriate.
- Be aware that elderly patients are more susceptible to hypotensive and electrolyte-altering effects and thus are at greater risk for shock and thromboembolism.
- Monitor patient for hypokalemia which may occur with brisk diuresis, inadequate oral electrolyte intake, or when cirrhosis is present. It may also occur during concomitant use of ACTH or corticosteroid therapy, intake of large amounts of licorice, or prolonged use of laxatives. Digoxin may exaggerate the metabolic effects of hypokalemia, especially cardiac effects. If patient is at high risk for hypokalemia, give potassium supplements along with furosemide, as prescribed.
- Expect to discontinue furosemide at maximum dosage if oliguria persists for more than 24 hours.
- Be aware that furosemide may worsen left ventricular hypertrophy, systemic lupus erythematosus, or renal retention and adversely affect glucose tolerance and lipid metabolism as well as increase risk of decreased renal function in patients at high risk for radiocontrast nephropathy after a procedure.
- Be aware that patients with hypoproteinemia, such as occurs with nephrotic syndrome, may weaken effect of furosemide and increase its ototoxicity potential.

- Notify prescriber if patient experiences hearing loss, vertigo, or ringing, buzzing, or sense of fullness in her ears. Drug may need to be discontinued.

## PATIENT TEACHING

- Instruct patient to take furosemide at the same time each day to maintain therapeutic effects. Urge her to take it as prescribed, even if she feels well.
- Instruct patient to take the last dose of furosemide several hours before bedtime to avoid sleep interruption from diuresis. If patient receives once-daily dosing, advise her to take the dose in the morning to avoid sleep disturbance caused by nocturia.
- Advise patient to change position slowly to minimize effects of orthostatic hypotension and to take furosemide with food or milk to reduce GI distress.
- Caution patient about drinking alcoholic beverages, standing for prolonged periods, and exercising in hot weather because these actions increase the hypotensive effect of furosemide.
- Emphasize the importance of weight and diet control, especially limiting sodium intake.
- Unless contraindicated, urge patient to eat more high-potassium foods and to take a potassium supplement, if prescribed, to prevent hypokalemia.
- Instruct patient to keep follow-up appointments with prescriber to monitor progress. Urge her to notify prescriber about persistent, severe nausea, vomiting, and diarrhea because they may cause dehydration.
- Inform diabetic patient that furosemide may increase blood glucose level, and advise her to check her blood glucose level frequently.

# G H I

**gabapentin**

**Gralise, Neurontin**

**gabapentin enacarbil**

**Horizant**

## **Class and Category**

*Pharmacologic class:* 1-amino-methyl cyclohexaneacetic acid

*Therapeutic class:* Anticonvulsant

## **Indications and Dosages**

➤ *To manage postherpetic neuralgia*

### **CAPSULES, ORAL SOLUTION, TABLETS (NEURONTIN)**

**Adults.** *Initial:* 300 mg on day 1, increased to 300 mg twice daily on day 2, increased to 300 mg three times daily on day 3, and increased gradually thereafter according to pain response, up to 600 mg three times daily. *Maximum:* 1,800 mg daily.

## **TABLETS (GRALISE)**

**Adults. Initial:** 300 mg once daily with evening meal on day 1, 600 mg once daily with evening meal on day 2, 900 mg once daily with evening meal on days 3 through 6, 1,200 mg once daily with evening meal on days 7 through 10, 1,500 mg once daily with evening meal on days 11 through 14, and 1,800 mg once daily with evening meal on day 15 and thereafter.

## **E.R. TABLETS (HORIZANT)**

**Adults. Initial:** 600 mg once daily in morning for 3 days, followed by 600 mg twice daily. *Maximum:* 600 mg twice daily.

**DOSAGE ADJUSTMENT** For patients taking Gralise who have a reduced creatinine clearance of 30 to 60 ml/min, dosage must be individualized and may need to be reduced. Patients with a creatinine clearance of less than 30 ml/min or who are receiving hemodialysis should not receive Gralise. For patients taking Neurontin who have a reduced creatinine clearance, including patients on hemodialysis, dosage reduced but reduction is highly individualized. For patients taking Horizant with a creatinine clearance between 30 and 59 ml/min, dosage reduced to 300 mg once daily in morning for 3 days, followed by 300 mg twice daily with further increase to 600 mg twice daily, as needed. For patients taking Horizant with a creatinine clearance between 15 and 29 ml/min, dosage reduced to 300 mg once daily in morning on days 1 and 3, followed by 300 mg once daily in morning with further increase to 300 mg twice daily, if needed. For patient with a creatinine clearance less than 15 ml/min and not on dialysis, dosage reduced to 300 mg once daily in morning every other day, followed by 300 mg once daily in morning, if needed. For patient with a creatinine clearance less than 15 ml/min and on

hemodialysis, 300 mg following every dialysis with further increase to 600 mg following every dialysis, if needed.

➤ *As adjunct to treat partial seizures*

## **CAPSULES, ORAL SOLUTION, TABLETS (NEURONTIN)**

**Adults and children 12 years and older.** *Initial:* 300 mg three times daily, increased gradually according to clinical response. *Maintenance:* 300 to 600 mg three times daily. *Maximum:* 3,600 mg daily with maximum time between doses not to exceed 12 hr.

**Children ages 3 to 11:** *Initial:* 10 to 15 mg/kg/day divided into 3 doses, increased, as needed, over a period of 3 days. *Maintenance for ages 3 to 4:* 40 mg/kg/day, given in 3 divided doses. *Maintenance for ages 5 to 11:* 25 to 35 mg/kg/day, given in 3 divided doses. *Maximum:* 50 mg/kg/day, given in 3 divided doses with maximum time between doses not to exceed 12 hr.

***DOSAGE ADJUSTMENT*** For patients taking Neurontin who have a reduced creatinine clearance, including patients on hemodialysis, dosage reduced but reduction is highly individualized.

➤ *To treat moderate to severe primary restless legs syndrome*

## **E.R. TABLETS (HORIZANT)**

**Adults.** 600 mg once daily with food at about 5 p.m.

***DOSAGE ADJUSTMENT*** For patients taking Horizant with a creatinine clearance between 30 and 59 ml/min, dosage reduced to 300 mg daily and then increased to 600 mg, as needed. For patients taking Horizant with a creatinine clearance between 15 and 29 ml/min, dosage reduced to 300 mg daily and not increased. For patients with a

creatinine clearance of less than 15 ml/min and not on hemodialysis, dosage reduced to 300 mg and given every other day. Patients taking Horizant with a creatinine clearance of less than 15 ml/min and receiving hemodialysis should not receive Horizant.

## **Mechanism of Action**

Gabapentin is structurally like gamma-aminobutyric acid (GABA), the main inhibitory neurotransmitter in the brain. Although gabapentin's exact mechanism of action is unknown, GABA inhibits the rapid firing of neurons associated with seizures. It also may prevent exaggerated responses to painful stimuli and pain-related responses to a normally innocuous stimulus to account for its effectiveness in relieving postherpetic neuralgia and restless legs syndrome symptoms.

## **Contraindications**

Hypersensitivity to gabapentin or its components

## **Interactions**

### **DRUGS**

*aluminum- and magnesium-containing antacids:* Decreased gabapentin bio-availability

*CNS depressants:* Increased CNS depression

*hydrocodone:* Decreased hydrocodone exposure

*morphine:* Increased CNS depression

## **Adverse Reactions**

**CNS:** Agitation, altered proprioception, amnesia, anxiety, apathy, aphasia, asthenia, ataxia, cerebellar dysfunction, chills, **CNS tumors**, delusions, depersonalization, depression, disappearance of aura, dizziness, dream disturbances, dysesthesia, dystonia, emotional lability, euphoria, facial paralysis, fatigue, fever, hallucinations, headache, hemiplegia, hostility, hyperkinesia, hyperreflexia, hypoesthesia, hypotonia, **intracranial hemorrhage**, lack of coordination, malaise, migraine headache, movement disorder, nervousness, occipital neuralgia, paranoia, paresis, paresthesia, positive Babinski's sign, psychosis, reflexes (absent or decreased), sedation, **seizures**, somnolence, stupor, **subdural hematoma**, **suicidal ideation**, syncope, tremor, vertigo

**CV:** Angina, hypertension, **hypotension**, murmur, palpitations, peripheral edema, peripheral vascular insufficiency, tachycardia, vasodilation

**EENT:** Abnormal vision, amblyopia, blepharospasm, cataracts, conjunctivitis, diplopia, dry eyes and mouth, earache, epistaxis, eye hemorrhage, eye pain, gingival bleeding, gingivitis, glossitis, hearing loss, hoarseness, increased salivation, inner ear infection, loss of taste, nystagmus, pharyngitis, photophobia, ptosis (bilateral or unilateral), rhinitis, sensation of fullness in ears, stomatitis, taste perversion, tinnitus, tooth discoloration, visual field defects

**ENDO:** Breast hypertrophy, hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, anorexia, constipation, diarrhea, elevated liver enzymes, fecal incontinence, flatulence, gastroenteritis, hemorrhoids, **hepatitis**, hepatomegaly, increased appetite, indigestion, jaundice, **melena**, nausea, thirst, vomiting

**GU:** **Acute renal failure**, anorgasmia, decreased libido, ejaculation disorders, impotence

**HEME:** Anemia, **coagulation defect**, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, arthritis, back pain, bone fractures, dysarthria, joint stiffness or swelling, muscle twitching, myalgia, positive Romberg test, **rhabdomyolysis**, tendinitis

**RESP:** **Apnea**, cough, dyspnea, pneumonia, pseudocroup

**SKIN:** Acne, alopecia, cyst, diaphoresis, dry skin, eczema, **erythema multiforme**, hirsutism, pruritus, purpura, rash, seborrhea, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, dehydration, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, elevated creatine kinase level, **hyponatremia**, increased risk of viral infection, lymphadenopathy, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Know that gabapentin capsules may be opened and mixed with applesauce, fruit juice, pudding, or water before administration.
- Administer initial dose for Neurontin brand at bedtime to minimize adverse reactions, especially ataxia, dizziness, fatigue, and somnolence. Administer Gralise brand with evening meal and initial dose of Horizant in the morning.
- Give drug at least 2 hours after an antacid.
- Don't exceed 12 hours between doses on a three-times-a-day schedule.
- Be aware that routine monitoring of blood gabapentin level isn't needed.

**WARNING** Know that to discontinue drug used to treat seizures or switch to a different anticonvulsant, expect to change gradually over at least 1 week, as prescribed, to avoid loss of seizure control. When gabapentin is discontinued after treating other indications, expect to reduce dosage, as ordered, over 1 week.

- Monitor renal function test results, as ordered, and expect to adjust dosage, if needed.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Be aware that the various brands of gabapentin are not interchangeable.
- Monitor patient for hypersensitivity, such as fever or lymphadenopathy suggestive of DRESS. Although rare, DRESS may be life-threatening. If suspected, notify prescriber immediately and expect gabapentin to be discontinued.

## PATIENT TEACHING

- Tell patient who has trouble swallowing gabapentin capsules, to open them and sprinkle contents in juice or on soft food immediately before use. Tell patient taking gabapentin extended-release tablets to swallow the tablet whole and not to chew, crush, or split the tablets.

**WARNING** Inform patient that an allergic reaction may occur after the first dose but it may occur at any time. If he experiences difficulty breathing or swelling of his lips, throat, or tongue, he should seek immediate emergency treatment and notify prescriber as drug will need to be discontinued.

- Instruct patient not to take drug within 2 hours after taking an antacid.
- Urge patient to take a missed dose as soon as he remembers. If the next dose is in less than 2 hours, tell him to resume his regular schedule. Caution against doubling the dose.
- Caution patient not to stop drug abruptly.
- Inform patient about possible ataxia, dizziness, drowsiness, and nystagmus. Advise him to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient how to prevent complications from adverse oral reactions (such as gingivitis) by encouraging patient to use good oral hygiene and to seek routine dental care.
- Explain that adverse effects usually are mild to moderate and decline with time.
- Urge patient to keep follow-up appointments with prescriber to check progress.
- Urge caregivers to watch closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately.

**galantamine hydrobromide**

**Razadyne, Razadyne ER**

**Class and Category**

*Pharmacologic class:* Cholinesterase inhibitor

*Therapeutic class:* Antidementia agent

## Indications and Dosages

➤ *To treat mild to moderate Alzheimer's-type dementia*

### ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 4 mg twice daily. Dosage increased to 8 mg twice daily after 4 wk, if tolerated and further increased to 12 mg twice a day after an additional 4 wk, if tolerated.

*Maximum:* 12 mg twice daily.

### E.R. CAPSULES

**Adults.** *Initial:* 8 mg daily. Dosage increased to 16 mg daily in 4 wk if tolerated, with further increase to 24 mg daily after another 4 wk, if tolerated. *Maximum:* 24 mg daily.

***DOSAGE ADJUSTMENT*** For patients with moderately impaired hepatic function or a creatinine clearance between 9 and 59 ml/min, maximum dosage shouldn't exceed 16 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

## Mechanism of Action

Reduces acetylcholine metabolism by competitively and reversibly inhibiting the brain enzyme acetylcholinesterase. Acetylcholine-producing neurons degenerate in the brains of patients with Alzheimer's disease. Inhibition of acetylcholinesterase increases the amount of acetylcholine, which is needed for nerve impulse transmission.

# Contraindications

Hypersensitivity to galantamine hydrobromide or its components

# Interactions

## DRUGS

*anticholinergics*: Possibly interference with cholinesterase activity

*cholinergic agonists such as bethanechol, cholinesterase inhibitors, neuromuscular blockers*: Possibly exaggerated effects of these drugs and galantamine

# Adverse Reactions

**CNS**: Aggression, asthenia, **CVA**, depression, dizziness, dysgeusia, fatigue, fever, hallucinations, headache, hypersomnia, insomnia, lethargy, malaise, **seizures**, somnolence, **suicidal ideation**, syncope, tremor

**CV**: **AV block (including complete)**, **bradycardia**, chest pain, hypertension, **MI**, myocardial ischemia

**EENT**: Blurred vision, rhinitis, tinnitus

**GI**: Abdominal pain, anorexia, diarrhea, elevated liver enzymes, flatulence, **GI bleeding**, **hepatitis**, indigestion, nausea, vomiting

**GU**: Hematuria, incontinence, **renal failure or insufficiency**, UTI

**HEME**: Anemia

**SKIN**: Acute generalized exanthematous pustulosis, **erythema multiforme**, **Stevens-Johnson syndrome**

**Other:** Dehydration, hypersensitivity reactions, **hypokalemia**, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Give galantamine twice daily with morning and evening meals, and ensure adequate fluid intake to prevent GI symptoms.
- Know that if therapy is interrupted for several days, expect to restart drug at lowest dose because benefits are lost when it is discontinued.
- Monitor patient's cardiovascular status closely because cholinesterase inhibitors like galantamine may have a depressive effect AV and sinoatrial nodes and may lead to AV block and bradycardia.
- Monitor patient for progressive deterioration of mental status because drug is less effective as Alzheimer's disease progresses and intact cholinergic neurons decrease.

### PATIENT TEACHING

- Instruct patient to take or caregiver to give regular-strength drug with morning and evening meals. Extended-release capsules should be given once in the morning, preferably with food.

- Tell patient or caregiver to stop drug immediately at the first sign of a skin rash and to notify the prescriber.
- Tell patient or caregiver to notify prescriber immediately if therapy stops for several days. Prescriber may restart at lowest dose.
- Instruct patient to maintain adequate fluid intake throughout galantamine therapy.
- Advise patient not to drive or perform activities requiring alertness, especially during first weeks of treatment, because drug may cause dizziness and drowsiness.
- Inform patient and family members that drug isn't a cure for Alzheimer's disease.

## galcanezumab-gnlm

### Emgality

## Class and Category

*Pharmacologic class:* Calcitonin gene-related peptide (CGRP) humanized monoclonal antibody

*Therapeutic class:* Antimigraine

## Indications and Dosages

➤ *To prevent migraine headaches*

### SUBCUTANEOUS INJECTION

**Adults.** *Loading:* 240 mg given as 2 consecutive injections of 120 mg each, followed by 120 mg monthly.

➤ *To treat episodic cluster headache*

## SUBCUTANEOUS INJECTION

**Adults.** 300 mg (administered as three consecutive injections of 100 mg each) at the onset of the cluster period, and then monthly until the end of the cluster period.

Route	Onset	Peak	Duration
SQ	Unknown	5 days	Unknown

## Mechanism of Action

Binds to calcitonin gene-related peptide ligand to block its binding to the receptor as a means of pain relief.

## Contraindications

Hypersensitivity to galcanezumab-gnlm or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**RESP:** Dyspnea

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, antibody formation to galcanezumab-gnlm, injection-site reactions (erythema, pain, pruritus)

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that women with migraines may be at increased risk of preeclampsia during pregnancy.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Administer galcanezumab-gnlm as a subcutaneous injection using the single-dose prefilled pen or single-dose prefilled syringe. Protect drug from direct sunlight. Prior to injection, allow drug to sit at room temperature for 30 minutes. Do not warm drug by using a heat source such as hot water or a microwave. Also, do not shake the pen or syringe. Prior to injecting drug, look for discoloration and particulate matter in the solution. Do not use if solution looks cloudy or has visible particles.
- Inject drug into patient's abdomen, back of the upper arm, buttocks, or thigh subcutaneously. Do not inject into areas where the skin is bruised, hard, red or tender.
- Monitor patient for hypersensitivity reactions such as dyspnea, rash, or urticaria. If a serious or severe reaction occurs such as anaphylaxis or angioedema, notify prescriber, expect drug to be discontinued, and initiate supportive therapy, as prescribed. Know that a hypersensitivity reaction may occur days after administration and that reaction may be prolonged.

## **PATIENT TEACHING**

- Instruct patient on how to administer a subcutaneous injection using the single-dose prefilled pen or single-dose prefilled syringe. Tell patient to protect drug from direct sunlight. Have patient allow drug to sit at room

temperature for 30 minutes before injection. Caution patient not to warm drug by using a heat source such as hot water or a microwave. Also caution patient not to shake the pen or syringe. Tell patient to look for discoloration and particulate matter in the solution before injecting drug. Tell patient not to use if solution looks cloudy or has visible particles.

- Tell patient to administer drug into her abdomen, back of the upper arm, buttocks, or thigh subcutaneously. Reinforce that she should not inject into areas where the skin is bruised, hard, red or tender. Tell patient to dispose of pen or syringe and needle in an appropriate container.
- Instruct patient receiving drug to prevent migraines that a loading dose will be given followed by a monthly dose. Instruct patient receiving drug to treat episodic cluster headache that an initial dose will be given requiring three separate injections at the onset of the cluster period and then monthly until the end of the cluster period.
- Advise patient that if a dose is missed, to administer drug as soon as it is remembered and then schedule the next monthly dose from the date delayed dose was given.

**WARNING** Instruct patient to seek medical attention if difficulty breathing, hives, rash, or swelling of face, lips, or throat occurs. Inform patient that an allergic reaction can occur days after administration and not to delay seeking treatment, as reaction may become prolonged and life-threatening.

## **ganciclovir**

### **Cytovene-IV**

## **Class and Category**

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiviral

# Indications and Dosages

- *To treat cytomegalovirus (CMV) retinitis in immunocompromised patients, including patients with acquired immunodeficiency syndrome (AIDS)*

## I.V. INFUSION

**Adults.** *Induction:* 5 mg/kg infused over 1 hr at a constant rate every 12 hr for 14 to 21 days. *Maintenance:* 5 mg/kg infused over 1 hr at a constant rate once daily for 7 days per wk. Alternatively, 6 mg/kg infused over 1 hr at a constant rate once daily for 5 days every wk.

- *To prevent CMV disease in transplant recipients at risk for CMV disease*

## I.V. INFUSION

**Adults.** *Induction:* 5 mg/kg infused over 1 hr at a constant rate every 12 hr for 14 to 21 days. *Maintenance:* 5 mg/kg infused over 1 hr at a constant rate once daily for 7 days per wk for 100 to 120 days post-transplantation. Alternatively, 6 mg/kg infused over 1 hr at a constant rate once daily for 5 days every wk for 100 to 120 days post-transplantation.

***DOSAGE ADJUSTMENT*** For patient with a creatinine clearance between 50 and 69 ml/min, dosage for induction and maintenance reduced by 50%. For patient with a creatinine clearance between 25 and 49 ml/min, dosage for induction reduced by half and dosage interval increased to every 24 hr while maintenance dosage reduced to 1.25 mg/kg every 24 hr. For patient with a creatinine clearance between 10 and 24 ml/min, induction dosage reduced to 1.25 mg/kg and dosage interval increased to every 24 hr while maintenance dosage reduced to 0.65 mg/kg every 24 hr. For patient with a creatinine clearance of less than 10

ml/min, induction dosage reduced to 1.25 mg/kg with dosage interval increased to only 3 times per wk following hemodialysis while maintenance dosage decreased to 0.65 mg/kg with dosage interval increased to only 3 times per wk following hemodialysis.

## Mechanism of Action

Initially, drug is phosphorylated and then slowly metabolized intracellularly into virus-infected cells. There it inhibits the viral DNA polymerase pUL54 to prevent replication of human CMV.

## Incompatibilities

Do not use bacteriostatic water for injection containing parabens, because it may cause precipitation to form.

## Contraindications

Hypersensitivity to ganciclovir, valganciclovir, or their components

## Interactions

### DRUGS

*amphotericin B, cyclosporine*: Increased risk of renal dysfunction

*dapsone, doxorubicin, flucytosine, hydroxyurea, pentamidine, tacrolimus, trimethoprim/sulfamethoxazole, vinblastine, vincristine, zidovudine*: Increased risk of myelosuppression or nephrotoxicity

*didanosine*: Increased risk of didanosine toxicity

*imipenem-cilastatin*: Increased risk of generalized seizures

*mycophenolate mofetil*: Increased risk for hematologic and renal toxicity

*probenecid*: Increased serum ganciclovir concentration with increased risk of ganciclovir toxicity

## Adverse Reactions

**CNS:** Agitation, amnesia, anxiety, aphasia, asthenia, chills, confusion, **CVA**, depression, dizziness, dream abnormality, dysesthesia, **encephalopathy**, extrapyramidal disorder, facial paralysis, fatigue, fever, hallucinations, headache, hypoesthesia, insomnia, **intracranial hypertension**, irritability, malaise, paresthesia, peripheral neuropathy, psychotic disorder, **seizures**, somnolence, thinking abnormality, third cranial nerve paralysis, tremor

**CV:** **Arrhythmias**, **cardiac arrest**, chest pain, **conduction disorder**, edema, elevated triglycerides, hypertension, **hypotension**, peripheral ischemia, phlebitis, **torsades de pointes**, vasculitis, vasodilatation, **ventricular tachycardia**

**EENT:** Cataracts, conjunctivitis, deafness, dry eyes or mouth, ear pain, loss of smell, macular edema, mouth ulceration, retinal detachment, taste disturbance, tinnitus, visual impairment, vitreous disorders

**ENDO:** Inappropriate antidiuretic hormone secretion

**GI:** Abdominal distention or pain, anorexia, cholelithiasis, cholestasis, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes, eructation, flatulence, **gastrointestinal perforation**, **hepatic dysfunction or failure**, **hepatitis**, intestinal ulcer, nausea, **pancreatitis**, vomiting

**GU:** Abnormal kidney function, decreased creatinine clearance, elevated serum creatinine, hematuria, **hemolytic uremic syndrome**, infertility, **kidney failure**,

renal tubular disorder, testicular hypotrophy, urinary frequency

**HEME:** Agranulocytosis, anemia including hemolytic, bone marrow failure, decreased platelet count, granulocytopenia, leukopenia, pancytopenia, thrombocyto-penia

**MS:** Arthralgia, arthritis, back pain, leg cramps, muscle spasms, myalgia, myasthenia, myelopathy, rhabdomyolysis

**RESP:** Bronchospasm, cough, dyspnea, pulmonary fibrosis

**SKIN:** Alopecia, dermatitis, diaphoresis, dry skin, exfoliative dermatitis, pruritus, rash, Stevens-Johnson syndrome, urticaria

**Other:** Acidosis, anaphylaxis, elevated blood alkaline phosphatase, generalized pain, hypercalcemia, hyponatremia, infection including *Candida*, injection-site inflammation, multiple organ failure, sepsis, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as mutagenic and teratogenic effects based on animal studies.
- A negative pregnancy test in women of childbearing age should be obtained before starting drug therapy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Breastfeeding should not be undertaken in patients receiving a transplant who are at risk for CMV.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## **REPRODUCTION**

- Women of childbearing age should use effective contraception during drug therapy and for at least 30 days following the last dose of the drug.
- Men should use condoms during drug therapy and for at least 90 days after the last dose of the drug when engaging in sexual activity.
- Drug may cause permanent or temporary female and male infertility.

## **Nursing Considerations**

- Be aware that ganciclovir is not recommended if the absolute neutrophil count is less than 500 cells/ $\mu$ L, hemoglobin is less than 8 g/dl, or the platelet count is less than 25,000 cells/ $\mu$ L.
- Use cautiously in patients with pre-existing cytopenias and in patients receiving myelosuppressive drugs or irradiation, because ganciclovir can cause hematologic toxicities. Also use cautiously in patients with impaired renal function, because ganciclovir levels will increase in these patients, requiring dosage adjustments.
- Expect female patients of childbearing age to have a pregnancy test done prior to receiving ganciclovir.
- Obtain a serum creatinine or creatinine clearance prior to starting ganciclovir therapy, as ordered, to establish a baseline for renal function, and then frequently throughout therapy to determine need for and degree of dosage adjustment.
- Wear disposable gloves during reconstitution and when wiping the outer surface of vial and table after reconstitution. To reconstitute ganciclovir, inject 10 ml of sterile water for injection, USP, into vial. Gently swirl vial to ensure complete wetting of contents. Continue swirling until a clear reconstituted solution is obtained. Look for particulate matter and discoloration prior to proceeding with infusion. Discard vial if present. Do

not refrigerate or freeze reconstituted solution. It may be kept at room temperature for 12 hours.

- Remove the appropriate volume of reconstituted solution (based on patient's weight) and add to 100 ml of an acceptable infusion fluid such as 0.9% Sodium Chloride, 5% Dextrose, Lactate, Ringer's Injection. Know that infusion concentrations greater than 10 mg/ml are not recommended. Refrigerate diluted infusion solution and use within 24 hours.

**WARNING** Avoid direct contact of the skin or mucous membranes with ganciclovir. If contact occurs, wash thoroughly with soap and water; rinse eyes thoroughly with plain water. Always wear disposable gloves during preparation and handling of solution. Know that guidelines issued for antineoplastic drugs should be considered in the handling and disposal of ganciclovir because it shares some of the properties of antitumor agents.

- Administer ganciclovir as an intravenous infusion over 1 hour, preferably with a plastic cannula, into a vein with adequate blood flow. Do not administer drug by rapid or bolus injection, which may increase toxicity as a result of excessive plasma levels; do not administer drug intramuscularly or subcutaneously because it may cause severe tissue irritation due to its high pH. Do not exceed the recommended dosage and infusion rate.
- Ensure that patient has adequate hydration while receiving ganciclovir to reduce adverse effects on renal function. Monitor patient's serum creatinine levels during therapy and assess patient for signs and symptoms of renal dysfunction, especially elderly and those patients receiving concurrent therapy with nephrotoxic drugs such as amphotericin B or cyclosporine.
- Monitor patient's complete blood counts with differential and platelet counts frequently throughout therapy, especially in patients in whom ganciclovir therapy or other nucleoside analogues have previously caused cytopenias, or in whom absolute neutrophil counts are less than 1,000 cells/ $\mu$ L at the beginning of treatment. Granulocytopenia usually occurs during the first or second week of treatment, but may occur at any time during treatment. Notify prescriber of hematologic abnormalities and expect possibility that drug will be discontinued. Cell counts usually begin to recover within 3 to 7 days after drug is discontinued. Colony-

stimulating factors may be helpful in increasing neutrophil and white blood cell counts.

- Expect patient to have frequent ophthalmologic examinations during treatment to monitor ganciclovir effectiveness.

**WARNING** Be aware that ganciclovir has the potential to cause cancer.

## **PATIENT TEACHING**

- Inform patient that frequent blood tests will have to be done throughout ganciclovir therapy because drug may cause blood toxicities. Stress importance of not missing any appointments. In addition, review signs and symptoms of anemia and infections and instruct patient to notify prescriber if present.
- Instruct patient to notify prescriber of persistent, severe, or unusual adverse effects, because drug can cause many adverse reactions, some of which could be serious.
- Stress importance of maintaining adequate hydration throughout ganciclovir therapy, because of potential adverse effect of drug on the kidneys.
- Inform patient that drug may cause temporary or permanent infertility and to discuss this with prescriber if concerned.
- Instruct women of childbearing age to use effective contraception during treatment and for at least 30 days following treatment, because drug may cause fetal toxicity. Instruct men to practice barrier contraception during and for at least 90 days following treatment.
- Tell patient to inform all prescribers of ganciclovir therapy, because drug can interact with other drugs.
- Advise patient not to perform any hazardous activities, such as driving, if cognitive impairment is present.
- Remind patient that ganciclovir is not a cure for CMV retinitis and that it is important to comply with ophthalmologic follow-up examinations.
- Advise mothers not to breastfeed infant while taking ganciclovir.

# gemfibrozil

**Lopid, Novo-Gemfibrozil (CAN)**

## Class and Category

*Pharmacologic class:* Fibric acid derivative

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *As adjunct (with diet) to treat hyper-lipidemia types IV and V; to reduce risk of coronary artery disease (CAD) in patients with type IIb hyperlipidemia who do not have a history of or symptoms of existing CAD, who have had an inadequate response to lifestyle changes or other pharmacologic agents, and have the following triad of lipid abnormalities: low HDL-cholesterol levels, elevated LDL-cholesterol levels, and elevated triglycerides*

## TABLETS

**Adults.** 600 mg 30 min before morning and evening meals.

Route	Onset	Peak	Duration
P.O.	2–5 days	4 wk	Unknown

## Mechanism of Action

May decrease hepatic triglyceride production by decreasing hepatic extraction of free fatty acids, inhibiting

peripheral lipolysis, and reducing VLDL synthesis. Gemfibrozil also may inhibit synthesis and increase clearance of apolipoprotein B, a carrier molecule for VLDL. In addition, it may accelerate turnover and removal of total cholesterol from the liver while increasing cholesterol excretion in the feces. As a result, total cholesterol, triglyceride, and VLDL levels decrease; the HDL level increases; and the LDL level is unaffected.

## Contraindications

Concurrent therapy with dasabuvir, repaglinide, selexipag, or simvastatin; gallbladder disease; hepatic or severe renal dysfunction, including primary biliary cirrhosis; hypersensitivity to gemfibrozil or its components

## Interactions

### DRUGS

*colchicine*: Increased toxicity of either drug; risk of myopathy, including rhabdomyolysis

*CYP2C8 substrates such as dabrafenib, loperamide, montelukast, paclitaxel, pioglitazone, rosiglitazone,*

*selexipag*: Increased plasma concentration of these drugs

*dasabuvir*: Increased dasabuvir plasma concentration increasing risk of QT prolongation

*enzalutamide*: Increased enzalutamide plasma concentration increasing risk of seizures

*HMG-CoA reductase inhibitors*: Increased risk of acute renal failure and rhabdomyolysis

*OATP1B1 substrates such as atrasentan, atorvastatin, bosentan, ezetimibe, fluvastatin, glyburide, olmesartan, pitavastatin, pravastatin, rifampin, rosuvastatin, SN-38*

*(active metabolite of irinotecan), simvastatin, valsartan:*

Increased plasma concentrations of these drugs

*oral anticoagulants such as warfarin:* Increased anticoagulation

*repaglinide:* Increased serum repaglinide level and risk of severe hypoglycemia

*resin-granule drugs such as colestipol:* Decreased blood gemfibrozil levels

## Adverse Reactions

**CNS:** Chills, fatigue, headache, hypoesthesia, paresthesia, **seizures**, somnolence, syncope, vertigo

**CV:** Vasculitis

**EENT:** Blurred vision, cataracts, hoarseness, retinal edema, taste perversion

**GI:** Abdominal or epigastric pain, cholelithiasis, colitis, diarrhea, flatulence, heartburn, **hepatoma**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Decreased male fertility, dysuria, impotence

**HEME:** Anemia, **bone marrow hypoplasia**, eosinophilia, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, myalgia, myasthenia, myopathy, myositis, **rhabdomyolysis**, synovitis

**RESP:** Cough

**SKIN:** Eczema, pruritus, rash

**Other:** **Anaphylaxis**, **angioedema**, increased risk of bacterial and viral infections, lupus-like symptoms, weight loss

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Monitor serum triglyceride and cholesterol levels, as appropriate.
- Periodically review CBC and liver enzymes, during therapy, as ordered.
- Know that if serum cholesterol and triglyceride levels don't improve within 3 months, expect to switch to a different drug, as prescribed.
- Monitor patient's prothrombin time, as ordered, if patient is also receiving warfarin therapy because gemfibrozil therapy may cause a drug interaction with warfarin. Warfarin dosage may need to be decreased to maintain prothrombin time at a level needed to prevent adverse bleeding effects.

## PATIENT TEACHING

- Instruct patient to take gemfibrozil 30 minutes before breakfast and 30 minutes before dinner.
- Advise patient to take a missed dose as soon as he remembers, unless it's nearly time for the next dose. Caution against doubling the dose.
- Emphasize importance of alcohol avoidance, a low-fat diet, regular exercise, and smoking cessation, as appropriate.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber if he experiences chills; cough; fever; hoarseness; lower back, side, or muscle pain; painful or difficult urination; severe abdominal pain with nausea and vomiting; tiredness; or weakness.
- If patient also takes an oral anticoagulant, urge him to report unusual bleeding or bruising; anticoagulant dosage may need to be reduced.
- Advise patient to keep scheduled appointments with prescriber to check progress.

## gemifloxacin mesylate

### Factive

## Class and Category

*Pharmacologic class:* Fluoroquinolone

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute bacterial exacerbation of chronic bronchitis caused by Haemophilus influenzae, H. parainfluenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

### **TABLETS**

**Adults.** 320 mg daily for 5 days.

- *To treat mild to moderate community-acquired pneumonia caused by Chlamydia pneumoniae, H. influenzae, Klebsiella pneumoniae, M. catarrhalis,*

*Mycoplasma pneumoniae*, or *S. pneumoniae* including multidrug-resistant strains

## **TABLETS**

**Adults.** 320 mg daily for 5 days (when due to *C. pneumoniae*, *H. influenzae*, *M. pneumoniae*, or *S. pneumoniae*) or 7 days (when due to *K. pneumoniae*, *M. catarrhalis*, or multidrug-resistant *S. pneumoniae*).

***DOSAGE ADJUSTMENT*** Dosage should be decreased to 160 mg daily in patients with creatinine clearance of 40 ml/min or less.

Route	Onset	Peak	Duration
P.O.	0.5-2 hr	Unknown	Unknown

## **Mechanism of Action**

Inhibits actions of the enzymes DNA gyrase and topoisomerase IV, which are required for bacterial growth, thereby causing bacterial cells to die.

## **Contraindications**

Hypersensitivity to gemifloxacin, other fluoroquinolones, or their components; myasthenia gravis

## **Interactions**

### **DRUGS**

*aluminum and magnesium antacids, didanosine as buffered or chewable tablets or pediatric powder for oral solution, ferrous sulfate, sucralfate, zinc or other metal cations:*  
Reduced blood gemifloxacin level

*antipsychotics; class IA antiarrhythmics, such as procainamide and quinidine; class III antiarrhythmics, such as amiodarone and sotalol; erythromycin; tricyclic antidepressants: Possibly prolonged QT interval*  
*probenecid: Increased blood gemifloxacin level*  
*warfarin: Possibly enhanced warfarin anticoagulant effects*

## **Adverse Reactions**

**CNS:** Agitation, anxiety, confusion, delirium, depression, disorientation, disturbance in attention, dizziness, fever, hallucinations, headache, **increased intracranial pressure**, insomnia, lightheadedness, memory impairment, nervousness, paranoia, peripheral neuropathy, restlessness, **seizures**, **suicidal ideation**, syncope, toxic psychosis, transient ischemic attack, tremors

**CV:** **Aortic aneurysm and dissection**, peripheral edema, **prolonged QT interval**, **supraventricular tachycardia**, vasculitis

**EENT:** Taste perversion

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, **acute hepatic necrosis or failure**, diarrhea, elevated liver enzymes, **hepatitis**, jaundice, nausea, **pseudomembranous colitis**, vomiting

**GU:** **Acute renal insufficiency or failure**, interstitial nephritis

**HEME:** **Agranulocytosis**, **aplastic or hemolytic anemia**, **elevated international normalized ratio (INR)**, **hemorrhage**, **leukopenia**, **pancytopenia**, **thrombocytopenia**, thrombocytosis

**MS:** Arthralgia, muscle weakness, myalgia, tendinitis, tendon rupture

**RESP:** Hypersensitivity pneumonitis

**SKIN:** Erythema multiforme, exfoliation, photosensitivity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, serum sickness

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Review patient's medical history before giving gemifloxacin, which shouldn't be used in patient with a history of prolonged QT interval, patient with uncorrected electrolyte disorders, or patient receiving class IA or III antiarrhythmics because of increased risk of prolonged QT interval. Monitor elderly patients closely because they may be more susceptible to prolonged QT interval.
- Be aware that an increased rate of aortic aneurysm and dissection may occur within two months of gemifloxacin therapy, especially in the elderly. Patients with known aortic aneurysm or patients who are at greater risk for aortic aneurysms should not receive gemifloxacin unless there are no alternative antibacterial treatments available.

- Use cautiously in patients with CNS disorders, such as epilepsy, or in those prone to seizures because gemifloxacin has caused increased intracranial pressure, seizures, and toxic psychosis. Monitor patient closely; if CNS alterations occur, notify prescriber immediately and expect drug to be discontinued.
- Monitor patient closely for hypersensitivity reaction, which may occur as soon as first dose. If patient has such evidence as angioedema, bronchospasm, dyspnea, itching, rash, shortness of breath, and urticaria, notify prescriber immediately and expect drug to be discontinued.
- Monitor patients prone to tendinitis, such as athletes, the elderly, and those taking corticosteroids, for reports of tendon inflammation, pain, or rupture. If present, notify prescriber. Expect gemifloxacin to be discontinued, patient placed on bed rest with no exercise of affected limb, and diagnostic tests ordered to confirm rupture.
- Notify prescriber about severe or prolonged diarrhea; it may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold gemifloxacin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patients, especially women under age 40 and postmenopausal women receiving hormone replacement therapy, for rash. It may appear days after therapy starts and resolve in 7 days. Notify prescriber immediately if rash occurs because it can be severe in about 10% of patients.
- Assess patient for evidence of peripheral neuropathy. Notify prescriber and expect to stop drug if patient complains of burning, numbness, pain, tingling, or weakness in extremities or if physical examination reveals deficits in light touch, motor strength, pain, position sense, temperature, or vibratory sensation.
- Monitor coagulation status, as ordered, for patient who takes warfarin because adding gemifloxacin may increase risk of bleeding.
- Know that fluoroquinolones like gemifloxacin have caused disabling and potentially irreversible serious adverse reactions from different body systems that can occur together in the same patient. These reactions can occur within hours to weeks after starting the drug and usually cause central nervous system effects, peripheral neuropathy, tendinitis, and tendon rupture. All ages of patients and patients without any preexisting risk factors have experienced these reactions. Notify prescriber and expect to discontinue gemifloxacin immediately at the first sign or symptom of any serious adverse reactions.

- Monitor patient's blood glucose levels, especially in diabetic patients, and for signs and symptoms of changes in blood glucose levels. Both symptomatic hyperglycemia and hypoglycemia may occur as a result of gemifloxacin therapy. If present, alert prescriber and initiate appropriate treatment, as prescribed. Also be aware that severe hypoglycemia has occurred with other fluoroquinolones. If a hypoglycemic reaction occurs, discontinue gemifloxacin administration immediately and initiate appropriate treatment for hypoglycemia.
- Monitor patient closely for changes in behavior or mood that may be caused by gemifloxacin-induced depression or worsening psychotic reactions potentially resulting in self-injurious behavior, such as suicide. Be aware that these reactions may occur even after just one dose. If present, notify prescriber immediately and expect to discontinue gemifloxacin therapy and institute precautions to keep patient safe until adverse effects have resolved.

## **PATIENT TEACHING**

- Tell patient to swallow tablet whole and take with a full glass of liquid.
- Warn patient not to increase dose because doing so may cause life-threatening cardiac arrhythmias.
- Instruct patient to complete entire course of therapy, even if symptoms decrease before prescription is finished.
- Caution patient to avoid sun exposure as much as possible while taking gemifloxacin. Patient who can't avoid sun exposure should apply sunscreen and wear a hat, sunglasses, and long sleeves to cover as much skin as possible.
- Urge caregivers to monitor patient closely for suicidal tendencies; if patient develops depression or worsening of psychotic behavior during therapy, instruct them to notify prescriber.
- Instruct patient to maintain adequate hydration throughout therapy to keep urine from becoming too concentrated. Tell patient to increase fluid intake if urine darkens or amount voided decreases.
- Caution patient to avoid hazardous activities until CNS effects of drug are known.
- Instruct patient to seek medical attention and notify prescriber immediately if he has tendon pain, tenderness, or rupture; evidence of hypersensitivity reaction, such as difficulty breathing, facial swelling, rash, or urticaria; or fainting spells or palpitations. Also advise patient to

stop taking gemifloxacin immediately and notify prescriber if any other persistent, serious, or worsening adverse effects occur.

- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Explain that bloody or watery stools can occur 2 or more months after therapy and can be serious, requiring prompt treatment.
- Tell patient to consult prescriber before starting any new medications, including OTC products, because gemifloxacin may interact adversely.
- Inform patient that aluminum and/or magnesium antacids; didanosine (Videx) buffered or chewable tablets and pediatric powder for oral solution (if prescribed); multivitamins containing zinc or other metal cations; and products containing iron shouldn't be taken within 3 hours before or 2 hours after gemifloxacin and that gemifloxacin should be taken at least 2 hours before sucralfate (if prescribed).
- Warn patient, especially diabetics, that gemifloxacin may alter blood glucose levels. Review signs and symptoms of hyperglycemia and hypoglycemia. Tell patient to immediately report symptomatic changes in blood glucose levels to prescriber and review how to treat hypoglycemia.

## gentamicin sulfate

### Cidomycin (CAN)

## Class and Category

*Pharmacologic class:* Aminoglycoside

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat serious bacterial infections caused by aerobic gram-negative organisms and some gram-positive organisms, including Enterobacter aerogenes, Escherichia coli, Klebsiella pneumoniae, Proteus*

*species (indole negative and indole positive),  
Pseudomonas aeruginosa, Serratia marcescens,  
Staphylococcus species*

## **I.V. INFUSION, I.M. INJECTION (PREFERRED ROUTE)**

**Adults and adolescents.** 3 mg/kg/day divided into 3 equal doses every 8 hr for 7 to 10 days. *For life-threatening infections:* Up to 5 mg/kg/day divided into 3 or 4 equal doses for 7 to 10 days or longer with dosage reduced as soon as possible to 3 mg/kg/day. Give I.V. infusion over 30 min to 2 hr.

**Children.** 2 to 2.5 mg/kg every 8 hr for 7 to 10 days. *For severe infections:* 3 to 6 mg/kg/day divided into 3 equal doses and given every 8 hr for 7 to 10 days or longer with dosage reduced as soon as possible to 3 mg/kg/day. Give I.V. infusion over 30 min to 2 hr.

**Infants.** 2 mg/kg every 8 hr for 7 to 10 days. Give I.V. infusion over 30 min to 2 hr.

**Premature or full-term neonates up to age 1 week.**

*Life-threatening infections:* 3 mg/kg every 12 hr for 7 to 10 days. Give I.V. infusion over 30 min to 2 hr.

**DOSAGE ADJUSTMENT** For adults with impaired renal function, highly individualized and dependent on degree of renal function and drug level. For adult patients receiving 14-hour hemodialysis twice weekly, 1 mg/kg at the end of each dialysis period has been suggested.

## **Mechanism of Action**

Binds to negatively charged sites on the outer cell membrane of bacteria, thereby disrupting the membrane's integrity. Gentamicin also binds to bacterial ribosomal

subunits and inhibits protein synthesis. Both actions lead to cell death.

## Incompatibilities

Don't administer gentamicin through same I.V. line as other drugs, especially beta-lactam antibiotics (cephalosporins and penicillins), because substantial mutual inactivation may occur. Give drugs through separate sites.

## Contraindications

Hypersensitivity to gentamicin, other aminoglycosides, or their components

## Interactions

### DRUGS

*loop diuretics (ethacrynic acid, furosemide), other aminoglycosides (kanamycin, neomycin, streptomycin):*

Increased risk of nephrotoxicity and ototoxicity

*neuromuscular blockers:* Prolonged respiratory depression, increased neuromuscular blockade

*other nephrotoxic drugs:* Increased risk of nephrotoxicity

*penicillins:* Inactivation of gentamicin by certain penicillins, increased risk of nephrotoxicity

## Adverse Reactions

**CNS:** Acute organic mental syndrome, confusion, depression, fever, headache, increased protein in cerebrospinal fluid, lethargy, myasthenia gravis-like

syndrome, **neurotoxicity**, peripheral neuropathy or **encephalopathy**, **pseudotumor cerebri**, **seizures**

**CV:** Hypertension, **hypotension**, palpitations

**EENT:** Blurred vision, increased salivation, **laryngeal edema**, ototoxicity, stomatitis, vision changes

**GI:** Anorexia, nausea, splenomegaly, transient hepatomegaly, vomiting

**GU:** **Nephrotoxicity**

**HEME:** Anemia, eosinophilia, **granulocytopenia**, increased or decreased reticulocyte count, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, leg cramps

**RESP:** **Pulmonary fibrosis**, **respiratory depression**

**SKIN:** Alopecia, generalized burning sensation, pruritus, purpura, rash, urticaria

**Other:** **Anaphylaxis**, injection-site pain, superinfection, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm as it crosses the placental barrier and may cause irreversible deafness and severe muscle weakness in the neonate.
- Drug is not recommended during pregnancy except in life-threatening situations.

### LACTATION

- Drug is present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Expect to obtain a body fluid or tissue specimen for culture and sensitivity testing, as ordered, before gentamicin therapy begins, or check test results, if available.
- Know that drug is best absorbed when given by I.V. route. Blood level is unpredictable after I.M. administration.
- For I.V. use, dilute each dose with 50 to 200 ml normal saline solution or D<sub>5</sub>W to yield no more than 1 mg/ml. Administer slowly over 30 minutes to 2 hours.
- Don't give gentamicin through same I.V. line as other drugs without first consulting pharmacist.
- Expect to adjust dosage based on peak and trough blood drug levels drawn after third maintenance dose, as prescribed.
- Know that drug should not be given to a pregnant patient because it can cause hearing loss in fetus.
- Know that any report of dizziness, hearing loss, or ringing in the ears should be taken very seriously. Hold drug with any report of these problems.

**WARNING** Be aware that when giving pediatric injectable form of drug, be alert for allergic reactions—including anaphylaxis and possibly life-threatening asthmatic episodes—because drug contains sodium bisulfite.

- Assess patient for evidence of other infections because gentamicin may cause overgrowth of nonsusceptible organisms.
- Be aware that premature infants, neonates, and elderly patients have an increased risk of nephrotoxicity.

## PATIENT TEACHING

- Emphasize importance of completing full course of gentamicin therapy.

- Instruct patient to report immediately adverse reactions, such as hearing loss, to avoid permanent effects.

# glimepiride

**Amaryl**

## Class and Category

*Pharmacologic class:* Sulfonylurea

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to control blood glucose level in type 2 diabetes mellitus*

### **TABLETS**

**Adults.** *Initial:* 1 to 2 mg daily with first meal of the day. Dosage increased by 1 to 2 mg every 1 to 2 wk as needed for blood glucose control. *Maximum:* 8 mg daily.

***DOSAGE ADJUSTMENT*** Initial dosage reduced to 1 mg daily and dosage titrated more slowly for the elderly and patients with renal impairment.

Route	Onset	Peak	Duration
P.O.	2–3 hr	Unknown	Over 24 hr

## Mechanism of Action

Stimulates insulin release from beta cells in pancreas. Glimepiride also increases peripheral tissue sensitivity to insulin, either by enhancing insulin binding to cellular receptors or by increasing the number of insulin receptors.

## Contraindications

Hypersensitivity to glimepiride, sulfonamide derivatives, or their components

## Interactions

### DRUGS

*ACE inhibitors, anabolic steroids, androgens, azole antifungals, bromocriptine, chloramphenicol, clarithromycin, clonidine, cyclophosphamide, disopyramide, fibric acid derivatives, fluconazole, fluoxetine, guanethidine, H<sub>2</sub>-receptor antagonists, insulin, magnesium salts, MAO inhibitors, methyldopa, NSAIDs, octreotide, oral anticoagulants, other oral hypoglycemic agents, oxyphenbutazone, pentoxifylline, phenylbutazone, phenylramidol, pramlintide, probenecid, propoxyphene, quinidine, quinolones, reserpine, salicylates, somatostatin analogs, sulfonamides, tetracyclines, theophylline, tricyclic antidepressants, urinary acidifiers: Increased risk of hypoglycemia*

*asparaginase, barbiturates, calcium channel blockers, cholestyramine, clonidine, clozapine, colestesvelam, corticosteroids, danazol, diazoxide, estrogens, glucagon, hydantoins, isoniazid, laxatives, lithium, morphine, nicotinic acid, olanzapine, oral contraceptives, phenothiazines, phenytoin, protease inhibitors, reserpine, rifabutin, rifampin, somatropin, sympathomimetics,*

*thiazide and other diuretics, thyroid hormones, urinary alkalinizers*: Increased risk of hyperglycemia  
*beta blockers, clonidine, reserpine*: Possibly hyperglycemia or masking of hypoglycemia signs  
*miconazole (oral)*: Increased risk of severe hypoglycemia  
*sympatholytic drugs such as beta blockers, clonidine, guanethidine, reserpine*: Reduced or absent hypoglycemic signs and symptoms

## ACTIVITIES

*alcohol use*: Altered blood glucose control (usually hypoglycemia)

## Adverse Reactions

**CNS**: Abnormal gait, anxiety, asthenia, chills, depression, dizziness, fatigue, headache, hypertonia, hypoesthesia, insomnia, malaise, migraine headache, nervousness, paresthesia, somnolence, syncope, tremor, vertigo

**CV**: **Arrhythmias**, edema, hypertension, vasculitis

**EENT**: Blurred vision, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, taste perversion, tinnitus

**ENDO**: **Hypoglycemia**, increased release of antidiuretic hormone secretion (SIADH)

**GI**: Anorexia, cholestasis, constipation, diarrhea, elevated liver enzymes, epigastric discomfort or fullness, flatulence, heartburn, hepatic porphyria, **hepatotoxicity**, hunger, jaundice, **liver failure**, nausea, proctocolitis, trace blood in stool, vomiting

**GU**: Darkened urine, decreased libido, dysuria, polyuria

**HEME**: **Agranulocytosis**, **aplastic anemia**, eosinophilia, **hemolytic anemia**, **leukopenia**, **pancytopenia**,

**thrombocytopenia, thrombocytopenic purpura**

**MS:** Arthralgia, leg cramps, myalgia

**RESP:** Dyspnea

**SKIN:** Allergic skin reactions, alopecia, diaphoresis, eczema, **erythema multiforme, exfoliative dermatitis**, flushing, lichenoid reactions, maculopapular or morbilliform rash, photosensitivity, pruritus, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis, angioedema**, disulfiram-like reaction, **hyponatremia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, it may cause neonatal hypoglycemia.
- Drug is not recommended during pregnancy because abnormal blood glucose levels during pregnancy are associated with a higher incidence of congenital abnormalities making insulin the preferred drug of choice during pregnancy.

### LABOR & DELIVERY

- At birth, neonate may experience birth injury, respiratory distress, and prolonged severe hypoglycemia, lasting 4 to 10 days if mother receives drug at time of delivery.
- If drug is used during pregnancy, expect it to be discontinued at least two weeks before expected delivery.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

- If breastfeeding occurs, infant should be monitored for signs and symptoms of hypoglycemia.

## Nursing Considerations

- Use cautiously in patients with glucose 6-phosphate dehydrogenase (G6PD) deficiency because glimepiride is a sulfonylurea, and sulfonylureas can cause hemolytic anemia in these patients.
- Monitor fasting blood glucose level to determine response to glimepiride. Expect to check glycosylated hemoglobin level every 3 to 6 months to evaluate long-term blood glucose control, or as ordered.
- Expect to switch patient to insulin therapy, as prescribed, during physical stress, such as infection, surgery, and trauma.

**WARNING** Expect a higher risk of hypoglycemia when giving glimepiride to a debilitated or malnourished patient or one with adrenal, hepatic, pituitary, or renal insufficiency. Also be aware that hypoglycemia may be more difficult to recognize in patients with autonomic neuropathy, the elderly, and patients taking beta blockers or other sympatholytic agents. Monitor blood glucose level closely.

- Be aware that patients taking the sulfonylurea, tolbutamide, may have an increased risk of dying from cardiovascular disease. Glimepiride has not been studied for cardiovascular mortality, but because it is also a sulfonylurea, monitor patients closely.
- Monitor patient closely for allergic reactions that could become life-threatening. If allergic reaction occurs, stop drug immediately and notify prescriber. Provide supportive care, as ordered. Give glimepiride at least 4 hours before administering colesevelam, if prescribed, to patient because colesevelam decreases exposure to glimepiride.
- Be aware that pregnant women should discontinue glimepiride at least 2 weeks before expected delivery to prevent prolonged severe hypoglycemia in the neonate and respiratory distress.

## PATIENT TEACHING

- Instruct patient to take glimepiride just before first meal of the day. Caution him not to skip the meal after taking drug.
- Urge patient not to skip doses or increase dosage without consulting prescriber.
- Urge patient to seek immediate emergency care and stop taking glimepiride if an allergic reaction occurs.
- Urge patient to report signs of hypoglycemia, such as anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Encourage patient to carry candy or other simple sugars to treat mild hypoglycemia.
- Advise patient to consult prescriber before taking any OTC drug.
- Urge patient to carry identification indicating that he has diabetes.
- Teach patient how to monitor his blood glucose level.
- Teach patient about diet, exercise, foot care, hygiene, signs of hyperglycemia and hypoglycemia, and ways to avoid infection.
- Instruct patient to notify prescriber about darkened urine, difficulty controlling his blood glucose level, easy bruising, fever, rash, sore throat, or unusual bleeding.
- Instruct patient to avoid direct sunlight and to wear sunscreen.
- Alert patient prescribed both glimepiride and colesevelam of the need to take glimepiride 4 hours before colesevelam.
- Tell women of childbearing age to notify prescriber if pregnancy is suspected or occurs. Inform pregnant women that glimepiride will have to be discontinued at least 2 weeks before expected delivery to prevent prolonged severe hypoglycemia in the newborn.
- Have mothers who are breastfeeding while taking glimepiride monitor their infant for signs of low blood sugar, which could be severe. If present, tell the mother to seek immediate emergency treatment for the infant.

## glipizide

### **Glucotrol, Glucotrol XL**

---

## Class and Category

*Pharmacologic class:* Sulfonylurea

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to control blood glucose level in type 2 diabetes mellitus*

### E.R. TABLETS

**Adults.** *Initial:* 5 mg daily with breakfast. Dosage increased, as needed, based on patient's glucose response. *Maximum:* 20 mg daily.

### TABLETS

**Adults.** *Initial:* 5 mg 30 min before first meal of day. Dosage adjusted by 2.5 to 5 mg every 2 to 3 days and given as a single dose, if dosage is 15 mg or less or given in 2 divided doses, if dosage exceeds 15 mg daily. *Maximum:* 15 mg once daily dose; or 40 mg daily for divided doses.

- *As adjunct to or replacement for insulin therapy in type 2 diabetes mellitus*

### CAPSULES, TABLETS

**Adults who receive 20 units of insulin or less.** Insulin discontinued and 5 mg given 30 min before the first meal of the day. Dosage adjusted, by 2.5 to 5 mg as needed, every 3 to 4 days and given as a single dose if dosage is 15 mg or less or divided and given twice daily if dosage exceeds 15 mg daily.

**Adults who receive more than 20 units insulin daily.**

*Initial:* 5 mg daily given 30 min before the first meal of the day, while insulin dosage decreased by one-half. Dosage adjusted by 2.5 to 5 mg, as needed, every 3 to 4 days and given as a single dose if dosage is 15 mg or less or divided and given twice daily if dosage exceeds 15 mg daily. Further insulin reductions are made based on clinical response.

**DOSAGE ADJUSTMENT** Initial dosage reduced to 2.5 mg daily if needed for patients over age 65 and those with hepatic disease.

Route	Onset	Peak	Duration
P.O.	10–30 min	30 min–2 hr	12–24 hr
P.O. (E.R.)	Unknown	Unknown	18–24 hr

## Mechanism of Action

Stimulates insulin release from beta cells in pancreas. Glipizide also increases peripheral tissue sensitivity to insulin, either by increasing insulin binding to cellular receptors or by increasing number of insulin receptors.

## Contraindications

Hypersensitivity to glipizide, sulfonylureas, or their components; ketoacidosis; sole therapy for type 1 diabetes mellitus

## Interactions

### DRUGS

*ACE inhibitors, anabolic steroids, androgens, angiotensin II receptor blocking agents, azole antifungals (selected), beta*

*blockers, bromocriptine, chloramphenicol, coumarins, disopyramide, fibric acid derivatives, fluconazole, fluoxetine, guanethidine, H<sub>2</sub>-receptor antagonists, insulin and other antidiabetic drugs, magnesium salts, MAO inhibitors, methyldopa, NSAIDs, octreotide, oral anticoagulants, oxyphenbutazone, pentoxifylline, phenylbutazone, pramlintide, probenecid, propoxyphene, quinidine, quinolones, salicylates, sulfonamide antibiotics, tetracycline, theophylline, tricyclic antidepressants, urinary acidifiers, voriconazole: Increased risk of hypoglycemia asparaginase, atypical antipsychotics, calcium channel blockers, cholestyramine, clonidine, colestesvelam, corticosteroids, danazol, diazoxide, estrogen, glucagon, hydantoins, isoniazid, lithium, morphine, niacin, nicotinic acid, oral contraceptives, phenothiazines, phenytoin, protease inhibitors, rifabutin, rifampin, somatropin, sympathomimetics, thiazides and other diuretics, thyroid drugs, urinary alkalinizers: Increased risk of hyperglycemia beta blockers, clonidine, reserpine: Possibly hyperglycemia or hypoglycemia miconazole (oral): Possibly severe hypoglycemia sympatholytic drugs such as beta blockers, clonidine, guanethidine, reserpine: Possible masking of hypoglycemia signs*

## **FOODS**

*all foods:* Possibly delayed absorption of immediate-release tablets if taken within 30 minutes of meal

## **ACTIVITIES**

*alcohol use:* Altered blood glucose control (usually hypoglycemia)

# Adverse Reactions

**CNS:** Abnormal gait, anxiety, asthenia, chills, depression, dizziness, fatigue, headache, hypertonia, hypoesthesia, insomnia, malaise, migraine headache, nervousness, paresthesia, somnolence, syncope, tremor, vertigo

**CV:** **Arrhythmias**, edema, hypertension, vasculitis

**EENT:** Blurred vision, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, taste perversion, tinnitus

**ENDO:** **Hypoglycemia**

**GI:** Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, elevated liver, enzymes, epigastric discomfort or fullness, flatulence, heartburn, hepatic porphyria, **hepatitis**, hunger, jaundice, nausea, proctocolitis, trace blood in stool, vomiting

**GU:** Darkened urine, decreased libido, dysuria, polyuria

**HEME:** **Agranulocytosis**, **aplastic anemia**, eosinophilia, **hemolytic anemia**, **leukopenia**, **pancytopenia**

**MS:** Arthralgia, leg cramps, myalgia

**RESP:** Dyspnea

**SKIN:** Allergic skin reactions, diaphoresis, eczema, **erythema multiforme**, **exfoliative dermatitis**, flushing, lichenoid reactions, maculopapular or morbilliform rash, photosensitivity, urticaria

**Other:** Disulfiram-like reaction

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, it may cause neonatal hypoglycemia.
- Drug is not recommended during pregnancy because abnormal blood glucose levels during pregnancy are associated with a higher incidence of congenital abnormalities making insulin the preferred drug of choice during pregnancy.

## **LABOR & DELIVERY**

- At birth, neonate may experience birth injury, respiratory distress, and prolonged severe hypoglycemia, lasting 4 to 10 days if mother receives drug at time of delivery.
- If drug is used during pregnancy, expect it to be discontinued at least 2 to 4 weeks before expected delivery.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for signs and symptoms of hypoglycemia.

## **Nursing Considerations**

- Use cautiously in patients with glucose 6-phosphate dehydrogenase deficiency because hemolytic anemia may develop. Monitor patient's CBC closely.
- Check blood glucose level at least three times daily for a patient switching from insulin to glipizide. Patients who take more than 40 units of insulin daily may need hospitalization during transition.
- Monitor fasting blood glucose level to determine response to drug. Expect to check glycosylated hemoglobin every 3 to 6 months or as ordered to evaluate long-term blood glucose control.
- Expect to switch patient to insulin therapy, as prescribed, during physical stress, such as infection, surgery, or trauma.

**WARNING** Be aware that the risk of hypoglycemia is higher when giving glipizide to a debilitated or malnourished patient or one with adrenal, hepatic, pituitary, or renal insufficiency.

- Expect to have glipizide discontinued 2 weeks before expected delivery in pregnant women to prevent neonatal hypoglycemia.
- Give glipizide extended release at least 4 hours before administering colesevelam, if prescribed, to patient because colesevelam decreases exposure to glipizide.

## **PATIENT TEACHING**

- Tell patient to take immediate-release form of glipizide 30 minutes before the first meal of the day. Tell patient prescribed the extended-release form of glipizide to take it with breakfast. Caution him not to skip the meal after taking the drug.
- Advise patient not to skip doses or increase the dosage without consulting prescriber.
- Urge patient to report evidence of hypoglycemia, such as anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Encourage patient to carry candy or other simple sugars to treat mild hypoglycemia.
- Caution patient to consult prescriber before taking any OTC drugs.
- Urge patient to carry identification indicating that he has diabetes.
- Teach patient how to monitor his blood glucose level.
- Teach patient about diet, exercise, foot care, hygiene, signs of hyperglycemia and hypoglycemia, and ways to avoid infection.
- Instruct patient to notify prescriber if he experiences darkened urine, easy bruising, fever, hypoglycemia or hyperglycemia, rash, sore throat, and unusual bleeding.
- Instruct patient to avoid direct sunlight and to wear sunscreen.
- Alert patient prescribed both extended-release form of glipizide and colesevelam of the need to take glipizide extended-release 4 hours before colesevelam.

- Advise pregnant women that glipizide will have to be temporarily withheld for about 2 to 4 weeks before expected delivery to prevent infant hypoglycemia, which could be severe. If present, tell mother to seek immediate emergency treatment for the infant.
- Tell mothers who are breastfeeding while taking glipizide to monitor their infant for hypoglycemia.

## glucagon hydrochloride

**Baqsimi, GlucaGen, Glucagon Diagnostic Kit, Glucagon Emergency Kit, Gvoke**

### Class and Category

*Pharmacologic class:* Pancreatic hormone

*Therapeutic class:* Antihypoglycemic, diagnostic aid adjunct

### Indications and Dosages

- *To provide emergency treatment of severe hypoglycemia*

#### **I.V., I.M., OR SUBCUTANEOUS INJECTION (GLUCAGEN, GLUCAGON)**

**Adults and children weighing more than 20 kg (44 lb) or, with GlucaGen, more than 25 kg (55 lb) and for children 6 years and older of unknown weight.** 1 mg, repeated in 15 min as needed. I.V. injection administered over 1 min.

**Children weighing 20 kg (44 lb) or less or, with GlucaGen, 25 kg (55 lb) or less or for children who are less than 6 years of unknown weight.** 0.5 mg repeated in 15 min, as needed. I.V. injection administered over 1 min.

## **SUBCUTANEOUS INJECTION (GVOKE)**

**Adults and children 12 years and older.** 1 mg, repeated in 15 min, if needed.

**Children age 2 to less than 12 years weighing 45 kg (99 lb) or more.** 1 mg, repeated in 15 min, if needed.

**Children age 2 to less than 12 years weighing less than 45 kg (99 lb).** 0.5 mg, repeated in 15 min, if needed.

## **NASAL SPRAY (BAQSIMI)**

**Adults and children age 4 and over.** 3 mg (1 spray) into one nostril. If no response after 15 minutes, dosage repeated.

➤ *To provide diagnostic assistance by inhibiting bowel peristalsis in radiologic examination of GI tract*

## **I.M. INJECTION**

**Adults.** *For relaxing duodenal bulb, duodenum, small bowel, or stomach:* 1 mg before procedure. *For relaxing colon:* 1 to 2 mg before the procedure. 1 to 2 mg before procedure.

## **I.V. INJECTION**

**Adults.** *For relaxing duodenal bulb, duodenum, small bowel, or stomach:* 0.2 to 0.5 mg before procedure. *For relaxing colon:* 0.5 to 0.75 mg before procedure. 0.25 to 2 mg given over 1 min before procedure.

Route	Onset	Peak	Duration
I.V.	5-20 min* <sup>†</sup>	Unknown	90 min* <sup>‡</sup>
I.M.	15-26 min* <sup>§</sup>	Unknown	90 min* <sup>  </sup>
SubQ	30-45 min*	Unknown	90 min*

\* For antihypoglycemic action.

<sup>†</sup> 45 sec to 1 min for smooth-muscle relaxation.

<sup>‡</sup> 9 to 25 min for smooth-muscle relaxation.

<sup>§</sup> 4 to 10 min for smooth-muscle relaxation.

<sup>||</sup> 12 to 32 min for smooth-muscle relaxation.

## Mechanism of Action

Increases production of adenylate cyclase, which catalyzes conversion of adenosine triphosphate to cAMP, a process that in turn activates phosphorylase. Phosphorylase promotes breakdown of glycogen to glucose (glycogenolysis) in the liver. As a result, blood glucose level increases and GI smooth muscles relax.

## Incompatibilities

Don't mix glucagon with sodium chloride or solutions that have a pH of 3.0 to 9.5; use with dextrose solutions instead.

## Contraindications

Glucagonoma (when used as a diagnostic aid), hypersensitivity to glucagon or its components, insulinoma, pheochromocytoma

## Interactions

## DRUGS

*anticholinergic drugs*: Increased gastrointestinal adverse reactions

*beta blockers*: Transient increase in blood pressure and pulse

*indomethacin*: Possibly loss of effectiveness to raise blood glucose; possibly even produce hypoglycemia

*insulin*: Antagonistic towards glucagon

*oral anticoagulants*: Possibly increased anticoagulant effects

## Adverse Reactions

**CNS**: Asthenia, dizziness, headache, somnolence

**CV**: Hypertension, **hypotension**, tachycardia

**EENT**: *Nasal form*: Altered taste, eye itchiness or redness, itchy ears or throat, nasal congestion or itching, running nose, sneezing, watery eyes

**ENDO**: **Hyperglycemia** (presence of diabetes mellitus during diagnostic testing), **hypoglycemia** (presence of glucagonoma or insulinoma)

**GI**: Abdominal pain, diarrhea, nausea, vomiting

**RESP**: **Bronchospasm**, **respiratory distress**, upper respiratory irritation (nasal form)

**SKIN**: **Necrolytic migratory erythema**, pallor, pruritus (nasal form), urticaria

**Other**: Hypersensitivity reactions (**anaphylactic shock**, **breathing difficulties**, generalized rash, **hypotension**), injection site reactions (discomfort, redness, swelling)

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Rouse patient as quickly as possible because prolonged hypoglycemia can cause cerebral damage.
- For I.V. use, reconstitute 1-mg vial of glucagon with 1 ml of diluent or 10-mg vial with 10 ml of diluent. Don't give more than 1 mg/ml. For large doses, dilute with sterile water for injection.
- Place unconscious patient on his side before injecting glucagon, to prevent aspiration of vomitus when he regains consciousness.
- Administer by slow I.V. injection over 1 minute to decrease risk of adverse reactions, such as tachycardia and vomiting.
- Expect to give I.V. dextrose if patient doesn't respond to glucagon.
- For intranasal use (Baqsimi), administer dose by inserting the device tip into one nostril and pressing the device plunger all the way in until the green line is no longer showing. The dose does not have to be inhaled. Each device contains one dose of glucagon and cannot be reused. If a repeat dose is needed, a new device must be used. The plunger should not be pushed or tested prior to use.
- For auto-injector and prefilled syringe (Gvoke) use, do not open foil pouch until ready to administer. Follow instructions printed on foil pouch label, carton, or the instructions for use.
- Monitor patients with diabetes mellitus receiving glucagon for diagnostic purposes for hyperglycemia and treat according to institutional protocol.

**WARNING** Prepare patient for cardiac monitoring when glucagon is used as a diagnostic aid because glucagon may increase blood pressure, myocardial oxygen demand, and pulse rate, which may become life-threatening in patients with cardiac disease.

- Give oral carbohydrates when patient is conscious or diagnostic procedure is completed to restore hepatic glycogen stores and prevent secondary hypoglycemia.
- Keep in mind that glucagon isn't effective in patients with depleted hepatic glycogen stores caused by such conditions as adrenal insufficiency, chronic hypoglycemia, and starvation.
- Expect to administer 5 to 10 mg of phentolamine mesylate intravenously, as ordered if glucagon is administered to a patient with undiagnosed pheochromocytoma to lower patient's blood pressure.
- Monitor patient for necrolytic migratory erythema, a skin rash common with glucagonomas that may present with bullae, erosions, and scaly, pruritic erythematous plaques following continuous glucagon infusion. These lesions may appear on patient's face, groin, legs, or perineum or may become more widespread. Notify prescriber and expect glucagon infusion to be discontinued, if possible. Know that treatment with corticosteroids is not effective in treating necrolytic migratory erythema.

## **PATIENT TEACHING**

- Instruct patient to monitor blood glucose level, especially with signs of hypoglycemia.
- Teach patient and family members how to recognize signs of hypoglycemia and when to notify prescriber.
- Advise patient to carry candy or other simple sugars to treat early hypoglycemia.
- Make sure unstable diabetic patients and family members know how to give glucagon subcutaneously, if prescribed, in case of hypoglycemia. Instruct family members to keep patient on his side and give him a carbohydrate when he awakens. Advise against giving fluids by mouth until patient is fully conscious.
- Teach family/caregivers how to administer nasal spray form of glucagon, if ordered. Tell them to administer dose by inserting the device tip into

one nostril and pressing the device plunger all the way in until the green line is no longer showing. The dose does not have to be inhaled. Each device contains one dose of glucagon and cannot be reused. If a repeat dose is needed, tell them to use a new device. The plunger should not be pushed or tested prior to use.

- Teach family how to use the Gvoke auto-injector/prefilled syringes, if prescribed.
- Instruct patient and family members to call for emergency medical assistance after glucagon treatment, especially if patient can't ingest oral glucose or if he's taking the sulfonylurea chlorpropamide, in case secondary hypoglycemia occurs.
- Urge patient to seek immediate emergency care if allergic reactions occur such as difficulty breathing, feeling light-headed, or a rash develops.

## glyburide

(glibenclamide)

**DiaBeta, Euglucon (CAN), Glynase**

### Class and Category

*Pharmacologic class:* Sulfonylurea

*Therapeutic class:* Antidiabetic

### Indications and Dosages

- *As adjunct to control blood glucose level in type 2 diabetes mellitus*

### MICRONIZED TABLETS

**Adults.** *Initial:* 1.5 to 3 mg daily with first meal of day, increased by up to 1.5 mg at weekly intervals, if needed. *Maintenance:* 0.75 to 12 mg as a single dose or in divided doses with meals. *Maximum:* 12 mg daily.

## NONMICRONIZED TABLETS

**Adults.** *Initial:* 2.5 to 5 mg daily with first meal of the day, increased by up to 2.5 mg at weekly intervals, if needed. *Maintenance:* 1.25 to 20 mg daily as a single dose or in divided doses with meals. *Maximum:* 20 mg daily.

**DOSAGE ADJUSTMENT** For conversion from insulin to glyburide for adults who use more than 40 units of insulin daily, initial dosage adjusted to 5 mg nonmicronized or 3 mg micronized glyburide as a single dose with 50% of usual insulin dose; glyburide dosage increased gradually, as needed. For adults who use less than 40 units but more than 20 units, glyburide started at 5 mg nonmicronized or 3 mg micronized daily as a single dose and insulin stopped. If patient is taking less than 20 units of insulin daily, usual glyburide dosage is used and insulin discontinued. For elderly patients or patients more sensitive to hypoglycemic drugs, initial dosage possibly reduced to 1.25 mg nonmicronized glyburide daily, gradually increased by 2.5 mg/wk, as needed; or 0.75 mg micronized daily, gradually increased by 1.5 mg/wk, as needed.

Route	Onset	Peak	Duration
P.O.*	1 hr	2.3-3.5 hr	12-24 hr
P.O.†	15-60 min	1-3 hr	24 hr

\* Micronized.

† Nonmicronized.

## Mechanism of Action

Stimulates insulin release from beta cells in the pancreas. Glyburide also increases peripheral tissue sensitivity to insulin either by enhancing insulin binding to cellular receptors or by increasing the number of insulin receptors.

## Contraindications

Concurrent therapy with bosentan; diabetic ketoacidosis; hypersensitivity to glyburide, sulfonylureas, or their components; type 1 diabetes mellitus

## Interactions

### DRUGS

*ACE inhibitors, anabolic steroids, azole antifungals, chloramphenicol, clarithromycin, disopyramide, drugs highly protein bound, fluoxetine, guanethidine, MAO inhibitors, NSAIDs, oxyphenbutazone, phenylbutazone, probenecid, quinolones, salicylates, sulfonamides:*

Increased risk of hypoglycemia

*calcium channel blockers, colestyramine, corticosteroids, estrogens, isoniazid, nicotinic acid, oral contraceptives, phenothiazines, phenytoin, sympathomimetics, thiazide diuretics and other diuretics, thyroid drugs:* Increased risk of hyperglycemia

*beta blockers:* Possibly hyperglycemia or masking of hypoglycemia signs

*bosentan:* Increased risk of elevated liver enzymes

*cyclosporine:* Increased cyclosporine plasma level and toxicity

*CYP2C9 and CYP3A4 inducers or inhibitors:* Possibly altered blood glucose levels

*miconazole (oral):* Possibly severe hypo-glycemia

*oral anticoagulants*: Possibly potentiated or weakened anticoagulant effects; increased risk of hypoglycemia  
*rifampin*: Decreased glyburide effectiveness

## **FOODS**

*high-fat foods*: Reduced bioavailability of nonmicronized glyburide

## **ACTIVITIES**

*alcohol use*: Altered blood glucose control (usually hypoglycemia)

## **Adverse Reactions**

**CNS**: Abnormal gait, anxiety, asthenia, chills, depression, dizziness, fatigue, headache, hypertonia, hypoesthesia, insomnia, malaise, migraine headache, nervousness, paresthesia, somnolence, syncope, tremor, vertigo

**CV**: **Arrhythmias**, edema, hypertension, vasculitis

**EENT**: Blurred vision, changes in accommodation, conjunctivitis, eye pain, pharyngitis, retinal hemorrhage, rhinitis, taste perversion, tinnitus

**ENDO**: **Hypoglycemia**

**GI**: Anorexia, constipation, cholestatic jaundice, diarrhea, elevated liver enzymes, epigastric discomfort or fullness, flatulence, heartburn, **hepatic failure** or porphyria, **hepatitis**, hunger, jaundice, nausea, proctocolitis, trace blood in stool, vomiting

**GU**: Decreased libido, dysuria, polyuria

**HEME**: **Agranulocytosis**, **aplastic anemia**, eosinophilia, **hemolytic anemia**, **leukopenia**, **pancytopenia**, purpura,

## thrombocytopenia

**MS:** Arthralgia, leg cramps, myalgia

**RESP:** Dyspnea

**SKIN:** Allergic skin reactions, bullous reactions, diaphoresis, eczema, erythema, **erythema multiforme**, **exfoliative dermatitis**, flushing, lichenoid reactions, maculopapular or morbilliform rash, photosensitivity, porphyria cutanea tarda, pruritus, urticaria

**Other:** **Angioedema**, disulfiram-like reaction, **hyponatremia**, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm. However, it may cause neonatal hypoglycemia.
- Drug is not recommended during pregnancy because abnormal blood glucose levels during pregnancy are associated with a higher incidence of congenital abnormalities making insulin the preferred drug of choice during pregnancy.

### LABOR & DELIVERY

- At birth, neonate may experience birth injury, respiratory distress, and prolonged severe hypoglycemia, lasting 4 to 10 days if mother receives drug at time of delivery.
- If drug is used during pregnancy, expect it to be discontinued at least two weeks before expected delivery.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

- If breastfeeding occurs, infant should be monitored for signs and symptoms of hypoglycemia.

## Nursing Considerations

- Use cautiously in patients with glucose 6-phosphate dehydrogenase deficiency because hemolytic anemia may develop. Monitor patient's CBC closely.
- Give glyburide as single dose before first meal of the day. If patient takes more than 10 mg daily or if severe GI distress occurs, give in 2 divided doses before meals.
- Monitor fasting blood glucose level to determine patient's response to glyburide. Expect to check glycosylated hemoglobin every 3 to 6 months or as ordered to evaluate long-term blood glucose control.
- Know that when patient switches from insulin to glyburide, check blood glucose level three times daily before meals.
- Be aware that micronized tablets aren't equal to nonmicronized tablets; they contain smaller particles, which affects drug bioavailability.

**WARNING** Expect a higher risk of hypoglycemia when giving drug to a debilitated or malnourished patient or one with adrenal, hepatic, pituitary, or renal insufficiency. Also be aware that hypoglycemia may be more difficult to recognize in patients with autonomic neuropathy, the elderly, and patients who are taking beta blockers or other sympatholytic agents. Monitor blood glucose level closely.

- Monitor patient with history of allergies to other sulfonamide derivatives closely because of increased risk of allergy to glyburide. If allergic reactions persist or worsen expect drug to be discontinued.
- Administer insulin as needed and prescribed during periods of increased stress, such as infection, surgery, and trauma.
- Arrange for diabetic teaching and consultation between patient and dietitian, if appropriate.

## PATIENT TEACHING

- Instruct patient to take glyburide just before first meal of the day. Caution him not to skip the meal after taking drug.
- Advise patient not to take nonmicronized glyburide with a high-fat meal because it may reduce glyburide bioavailability.
- Caution patient to avoid skipping doses, discontinuing glyburide, or taking OTC drugs without first consulting prescriber.
- Teach patient how to monitor his blood glucose level and when to notify prescriber about changes.
- Urge patient to report signs of hypoglycemia: anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Suggest that patient carry candy or other simple sugars to treat mild hypoglycemia.
- Urge patient to avoid alcohol because it increases the risk of hypoglycemia.
- Advise patient to carry identification indicating that he has diabetes.
- Teach patient about diet, exercise, foot care, hygiene, signs of hyperglycemia and hypoglycemia, and ways to avoid infection.
- Instruct patient to notify prescriber if he experiences easy bruising, fever, hypoglycemia or hyperglycemia, rash, sore throat, and unusual bleeding.
- If photosensitivity is a problem, instruct patient to avoid direct sunlight and to wear sunscreen.

**glycopyrrolate**

**Cuvposa, Lonhala Magnair, Seebri  
Neohaler**

## Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Antiarrhythmic, anticholinergic, bronchodilator, cholinergic adjunct

## Indications and Dosages

- *As adjunct to treat peptic ulcer disease*

### **TABLETS**

**Adults and adolescents using 1 mg tablet.** *Initial:* 1 mg three times daily (morning, afternoon, bedtime) with some adults requiring a 2 mg dose in evening at bedtime.

**Adults using the 2 mg tablet.** 2 mg twice daily or three times daily.

### **I.M. INJECTION, I.V. INFUSION**

**Adults and adolescents.** 0.1 to 0.2 mg every 4 hr, as needed. *Maximum:* 3 to 4 doses daily. I.V. infusion given over 15 to 20 min.

- *To reduce gastric acid and respiratory secretions before anesthesia*

### **I.M. INJECTION**

**Adults and children over age 2.** 0.004 mg/kg 30 to 60 min before anesthesia or when preanesthesia sedative or opioid is given.

**Infants age 1 month to 2 years.** Up to 0.009 mg/kg 30 to 60 min before anesthesia or when preanesthesia sedative or opioid is given.

- *To counteract intraoperative and anesthesia-induced arrhythmias*

### **I.V. INJECTION**

**Adults and adolescents.** 0.1 mg, repeated every 2 to 3 min, if needed.

**Children over age 2.** 0.004 mg/kg. Dose repeated every 2 to 3 min, if needed. *Maximum:* 0.1 mg as a single dose.

- *To reverse neuromuscular blockade due to nondepolarizing muscle relaxants*

## **I.V. INJECTION**

**Adults and children over age 2.** 0.2 mg glycopyrrolate for each 1 mg neostigmine or 5 mg pyridostigmine.

- *To reduce chronic severe drooling in patients with neurologic conditions associated with problem drooling, such as cerebral palsy*

## **ORAL SOLUTION (CUVPOSA)**

**Children ages 3 to 16.** *Initial:* 0.02 mg/kg three times daily 1 hr before meals or 2 hr after meals, increased in increments of 0.02 mg/kg every 5 to 7 days, as needed and based on response and adverse reactions. *Maximum:* 0.1 mg/kg three times daily not to exceed 1.5 to 3 mg per dose based on weight of child.

- *To provide long-term, maintenance treatment of airflow obstruction in patients with chronic obstructive pulmonary disease, including chronic bronchitis and/or emphysema*

## **ORAL INHALER (SEEBRI NEOHALER)**

**Adults.** 15.6 mcg (1 capsule) inhaled using Neohaler device twice daily, once in the morning and once in the evening.

## **ORAL INHALATION (LONHALA MAGNAIR)**

**Adults.** 25 mcg (1 vial) inhaled using the Magnair device twice daily, once in the morning and once in the evening.

Route	Onset	Peak	Duration
P.O.	60 min	Unknown	8-12 hr
Inhaled	Immediate	5 min	Unknown
I.V.	1 min	Unknown	2-3 hr*
I.M., SubQ	15-30 min	30-45 min	2-3 hr*

\* For vagal blocking effect; up to 7 hr for reduction of saliva.

## Mechanism of Action

Inhibits acetylcholine's action on postganglionic muscarinic receptors throughout the body. Depending on the receptors' location, glycopyrrolate produces various effects, such as:

- reducing the volume and acidity of gastric secretions
- controlling excessive bronchial, pharyngeal, and tracheal secretions and dilating the bronchi
- inhibiting vagal stimulation of the heart
- relaxing smooth muscle in the GI, GU, and respiratory tracts.

## Incompatibilities

Don't mix glycopyrrolate with alkaline drugs or solutions that have a pH over 6.0 because drug stability may be affected. A pH over 6.0 may occur if glycopyrrolate is mixed with dexamethasone sodium phosphate or LR solution. Gas or precipitate may form if glycopyrrolate is mixed in same syringe as chloramphenicol, diazepam, methohexital sodium, pentobarbital sodium, secobarbital sodium, sodium bicarbonate, or thiopental sodium.

# Contraindications

*For all forms:* Hypersensitivity to glycopyrrolate or its components; *For Cuvposa:* Angle-closure glaucoma; concomitant use of solid oral dosage forms of potassium chloride; hemorrhage with unstable cardiovascular status; ileus; intestinal atony; myasthenia gravis; severe ulcerative colitis; toxic megacolon; *For generic glycopyrrolate in treatment of peptic ulcer:* glaucoma, intestinal atony in the debilitated or elderly patient, myasthenia gravis, obstructive GI or uropathy disorders, paralytic ileus, severe ulcerative colitis, toxic megacolon complicating ulcerative colitis, unstable cardiovascular status in acute hemorrhage

# Interactions

## DRUGS

*amantadine, other anticholinergics:* Increased anticholinergic effects of glycopyrrolate  
*anticholinergics, antiparkinsonian drugs, phenothiazines, tricyclic antidepressants:* Possibly increased anticholinergic effects  
*atenolol, metformin:* Increased effects of these drugs. Possibly potentiated atenolol effects  
*digoxin (slow dissolution oral tablets):* Possibly potentiated digoxin effects  
*potassium chloride (Cuvposa):* Possibly arrested or decreased passage of potassium chloride through the GI tract  
*potassium chloride in a wax matrix (generic glycopyrrolate):* Possibly increased severity of potassium chloride-induced GI lesions

# Adverse Reactions

**CNS:** Confusion, difficulty speaking, dizziness, drowsiness, headache, insomnia, nervousness, weakness

**CV:** **Bradycardia** (low doses), **heart block**, palpitations, **prolonged QT interval**, tachycardia (high doses)

**EENT:** Blurred vision, cycloplegia, dilated pupils, dry mouth, increased intraocular pressure, loss of taste, mydriasis, nasal congestion, nasopharyngitis, oropharyngeal pain, photophobia, sinusitis, taste perversion

**GI:** Abdominal distention, constipation, dysphagia, nausea, vomiting

**GU:** Impotence, urinary hesitancy, urine retention, UTI

**RESP:** Dyspnea, **paradoxical bronchospasm**

**SKIN:** Decreased sweating (**heat exhaustion**), dry skin, flushing, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that inhaler and inhalation forms of glycopyrrolate should not be used in patients during acutely deteriorating or potentially life-threatening episodes of COPD nor should it be used for relief of acute symptoms.
- Use glycopyrrolate cautiously in patients with autonomic neuropathy, hepatic disease, hiatal hernia, mild to moderate ulcerative colitis, narrow-angle glaucoma, or prostatic hypertrophy because drug's anticholinergic effect can worsen these conditions; gastric ulcer because drug may delay gastric emptying; and renal disease because drug excretion may be altered.
- Give tablets 30 to 60 minutes before meals.
- Give 2-mg oral dose at bedtime to ensure overnight control of symptoms, as needed and prescribed.
- For I.V. use, administer by direct injection without diluting. Or inject into tubing of flowing I.V. solution unless it contains an alkaline drug or sodium bicarbonate.
- For inhalation purpose using Seebri Neohaler, administer capsules only in the provided neohaler device and at the same time of the day (once in the morning and once in the evening). Keep capsules in the blister container and only remove immediately before use.
- For inhalation purpose using Lonhala, know that drug should only be administered with Magnair at the same time of day. Drug vials should be kept in the foil pouch and only removed immediately before use.

**WARNING** Monitor patient closely after administration for an immediate hypersensitivity reaction such as patient experiencing difficulty breathing or swallowing; rash; swelling of the patient's face, lips, or throat; or urticaria. Notify prescriber at once, expect drug to be discontinued, and be prepared to provide emergency supportive care, as ordered.

- Be aware that closure system contains dry natural rubber that may cause hypersensitivity reaction if handled by or used to inject someone with latex sensitivity.
- Notify prescriber if patient using inhaled form of glycopyrrolate is experiencing lack of control of respiratory symptoms exhibited by increased bronchoconstriction or patient's prescribed short-acting beta<sub>2</sub>-

agonist becomes less effective or patient needs to use it more as these are markers of deterioration of the patient's respiratory status indicating that glycopyrrolate may no longer be effective.

- Use continuous cardiac monitoring, as ordered, to assess patient for arrhythmias during drug administration.

**WARNING** Check all doses carefully because even a slight overdose can lead to toxicity.

- Adjust the room temperature and make sure patient is well hydrated to prevent overheating caused by decreased sweating.

## **PATIENT TEACHING**

- Advise patient to take glycopyrrolate tablets 30 to 60 minutes before meals or inhaler once in the morning and once in the evening.
- Instruct patient on how to load and use prescribed inhaler. Remind patient not to remove capsule from blister until immediately before use and not to push the capsule through the foil covering. Tell patient to place capsule into capsule chamber, not the mouthpiece. After closing chamber, patient should hear a click. Then tell patient to hold the inhaler upright and then press firmly both piercing buttons at the same time. Patient should hear a click signaling need to release buttons. Stress importance of not piercing capsule more than once, not swallowing capsule, using two capsules at one time or more than two capsules daily. Once drug is inhaled, instruct patient to remove the empty capsule shell as it should never be left in the device. Show patient how to clean inhaler device.
- Instruct patient how to administer inhalation form of drug using Magnair. Remind patient that device should not be used to administer any other medication. Tell patient to store the vials in the sealed foil pouch and to open the pouch only to remove a vial immediately before use. Inform patient that unopened vials should be returned to the opened foil pouch and used at his next treatment and discarded if not used within 7 days, as the drug may be ineffective. Also tell patient not to use 2 vials at one time and not to use more than 2 vials in a day. Patient should take care when discarding the plastic vials because they pose a danger of choking to young children, due to their small size.
- Inform patient that the prescribed inhaler or inhalation form of drug is not to be used to treat acute respiratory symptoms. If patient needs to use his rescue inhaler more often or his symptoms worsen, he should notify prescriber. If acute bronchospasms occur, he should stop taking drug

immediately, seek emergency medical treatment, and notify prescriber as drug needs to be discontinued.

- Instruct patient to consult prescriber before taking any OTC drugs.
- Caution patient about possible dizziness and drowsiness and need to avoid hazardous activities until drug's effects are known.
- Suggest patient to use sugarless hard candy, ice, or saliva substitute to relieve dry mouth.
- Instruct patient to avoid exertion and hot environments because he's prone to heat exhaustion while taking glycopyrrolate.
- Urge patient to drink at least eight glasses of water daily, unless contraindicated.
- Tell patient to notify prescriber about abdominal distention, eye pain, irregular heartbeat, sensitivity to light, severe constipation, or trouble breathing or urinating.
- Advise patient to wear sunglasses in bright light.
- Advise patient to void before taking each dose, if urinary hesitancy occurs and to notify prescriber.

## golimumab

### Simponi, Simponi Aria

## Class and Category

*Pharmacologic class:* Tumor necrosis factor (TNF) blocker

*Therapeutic class:* Biologic disease-modifying antirheumatic drug (DMARD)

## Indications and Dosages

- *To treat active psoriatic arthritis or ankylosing spondylitis with or without methotrexate or other nonbiologic Disease Modifying Antirheumatic Drugs (DMARDs)*

## **SUBCUTANEOUS INJECTION (SIMPONI)**

**Adults.** 50 mg monthly.

## **I.V. INFUSION (SIMPONI ARIA)**

**Adults.** 2 mg/kg infused over 30 min at weeks 0 and 4, then every 8 wk thereafter.

- *To treat moderate to severe active rheumatoid arthritis in combination with methotrexate*

## **I.V. INFUSION (SIMPONI ARIA)**

**Adults.** 2 mg/kg infused over 30 minutes at weeks 0 and 4, then every 8 wk thereafter.

## **SUBCUTANEOUS INJECTION (SIMPONI)**

**Adults.** 50 mg monthly.

- *To treat moderate to severe active ulcerative colitis in patients who have demonstrated corticosteroid dependence or who have had an inadequate response to or failed to tolerate 6-mercaptopurine, azathioprine, oral aminosalicylates, or oral corticosteroid*

## **SUBCUTANEOUS INJECTION (SIMPONI)**

**Adults.** *Initial:* 200 mg at week 0, followed by 100 mg at week 2. *Maintenance:* 100 mg every 4 wk.

Route	Onset	Peak	Duration
SubQ	Unknown	2–6 days	Unknown

---

## Mechanism of Action

Binds to a cytokine protein, tumor necrosis factor-alpha (TNF-alpha), to block interaction with its receptors, which prevents biological activity of TNF-alpha. Elevated TNF-alpha levels in the blood, joints, and synovium may play an important role in pathophysiology of such inflammatory diseases as ankylosing spondylitis, psoriatic arthritis, rheumatoid arthritis, and ulcerative colitis. Reduced TNF-alpha activity in these disorders improves signs and symptoms.

## Incompatibilities

Don't mix golimumab solution for intravenous infusion with other drugs, as incompatibilities are unknown.

## Contraindications

Hypersensitivity to golimumab or its components

## Interactions

### DRUGS

*abatacept, anakinra, rituximab*: Possibly increased risk of serious infection

*cytochrome P-450 substrates such as cyclosporine, theophylline, warfarin*: Effects or blood levels of these drugs may change when golimumab therapy starts or stops  
*live vaccines, therapeutic infectious agents such as BCG bladder instillation for treatment of cancer*: Increased risk of adverse vaccine effects

*methotrexate*: Decreased clearance of golimumab

# Adverse Reactions

**CNS:** Demyelinating disorders both central and peripheral, dizziness, fever, paresthesia

**CV:** **Congestive heart failure**, hypertension

**EENT:** Nasopharyngitis, oral herpes, pharyngitis, rhinitis, sinusitis

**GI:** Elevated liver enzymes, nausea

**HEME:** **Agranulocytosis, aplastic anemia, leukemia, leukopenia, neutropenia, thrombocytopenia**

**RESP:** Bronchitis, dyspnea, **interstitial lung disease**, pneumonia, tuberculosis, upper respiratory tract infection

**SKIN:** Bullous skin reactions, cellulitis, lichenoid reactions, **melanoma, Merkel cell carcinoma**, new or worsening psoriasis, pruritus, rash, skin exfoliation, urticaria

**Other:** Abscess; **anaphylaxis**; antibody formation; bacterial (including *Legionella* and *Listeria*), fungal (including invasive), mycobacterial, parasitic, or viral infections (including **reactivation of hepatitis B infection** in chronic carriers); injection-site erythema; lupus-like syndrome; **malignancies such as lymphomas**; sarcoidosis; **sepsis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, it does cross the placenta during the third trimester of pregnancy and may affect immune response of the infant after birth.
- If drug is given during pregnancy, know that infant is at increased risk for infection. Administration of live vaccines to infants exposed to drug in

utero is not recommended for 6 month's following the mother's last injection during pregnancy.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, treatment of latent tuberculosis must start before golimumab therapy starts, as prescribed. Also antituberculosis therapy may be started if patient has a history of active or latent tuberculosis, if adequate therapy can't be confirmed, or if patient has a negative test for latent tuberculosis but also has risk factors for tuberculosis.

**WARNING** Know that if patient has evidence of an active infection when drug is prescribed, golimumab therapy shouldn't start until infection has been treated. Monitor all patients for bacterial (including *Legionella* and *Listeria*), fungal, mycobacterial, parasitic, or viral infections during therapy, especially those receiving immunosuppressants. Know that the infection could become life-threatening and affect multiple organs. If a serious infection, an opportunistic infection, or sepsis develops, expect prescriber to stop drug and start appropriate antimicrobial therapy. Monitor patient closely for tuberculosis throughout golimumab therapy because active tuberculosis has occurred in patients during and after treatment of latent tuberculosis.

- Know that patients with a history of cancer, except those successfully treated for nonmelanoma skin cancer, should be thoroughly evaluated before golimumab therapy starts because treatment may pose more risks than benefits. Patients with rheumatoid arthritis may have a higher risk

than the general population for developing leukemia while taking a TNF blocker such as golimumab.

- Use golimumab cautiously in patients with congestive heart failure, demyelinating disorders such as multiple sclerosis, and hematologic cytopenias because these disorders may develop or become worse with golimumab therapy.
- Use golimumab cautiously in patients with recurrent infection or increased risk of infection, patients who live in regions where histoplasmosis and tuberculosis are endemic, and patients with a history of hepatitis B infection because drug increases risk of infection.
- Be aware that needle cover of syringe used for subcutaneous injection contains dry rubber and should not be handled by anyone with a latex allergy.
- Take golimumab out of the refrigerator 30 minutes before giving subcutaneous injection to allow time for drug to warm up to room temperature. Never warm drug in any other way. Rotate subcutaneous injection sites. If more than one subcutaneous injection is required, administer the injections at different sites on the body.
- Know that each 4-ml vial used for intravenous infusion contains 50 mg of golimumab. Dilute the total volume of the drug solution with normal saline or half normal saline for intravenous infusion for a final volume of 100 ml. Gently mix. Discard any unused solution remaining in the vials. Use within 4 hours, keeping diluted solution at room temperature.
- Inspect diluted solution for intravenous infusion-prior to infusion for particulate matter or discoloration. Do not use if present. Use only an infusion set with an in-line, low protein-binding, nonpyrogenic, sterile filter (pore size 0.22 micrometer or less). Do not infuse concomitantly in the same intravenous line with other drugs. Infuse the diluted solution over 30 minutes.
- Monitor patient, especially young adult males, for signs and symptoms of malignancies. Although lymphomas account for about half of all malignancies associated with golimumab therapy, leukemia and rare malignancies, including melanomas and Merkel cell carcinoma, have also occurred. Report any persistent or unusual signs and symptoms to prescriber.

## **PATIENT TEACHING**

- Explain that first injection of golimumab must be administered with a healthcare professional present.

- Teach patient or caregiver how to give golimumab as a subcutaneous injection at home, if applicable. Tell him to let prefilled syringe or autoinjector sit at room temperature outside carton for 30 minutes before injecting. Tell him not to warm drug in any other way and not to remove needle cover or cap while letting golimumab warm up.
- Teach patient using autoinjector not to pull the device away from his skin until he hears a first “click” and then a second “click” indicating the injection is finished. It may take up to 15 seconds before second click is heard and, if device is pulled away from the skin before the second click, a full dose may not have been given.
- Emphasize need to inject full amount in prefilled syringe to obtain correct dose. Instruct patient to discard any drug left in prefilled syringe or autoinjector.
- Tell patient requiring multiple injections to administer the injections at different sites on the body.
- Alert patient that needle cover contains natural dry rubber and should not be handled by anyone with a latex allergy.
- Instruct patient or caregiver to use a puncture-resistant container to dispose of needles and syringes at home.
- Inform patient that drug must be refrigerated (not frozen).
- Urge patient to check expiration dates and not to use outdated drug.
- Teach patient to rotate injection sites and never to give injection into an area where skin bruised, hard, red or is tender.
- Explain that tuberculosis may occur during golimumab therapy. Instruct him to report low-grade fever, persistent cough, and wasting or weight loss, to prescriber.
- Teach patient how to recognize evidence of bleeding disorders and infection and to tell prescriber if they occur; drug may need to be stopped. Advise patient to avoid people with infections and to have all prescribed laboratory tests performed.
- Inform patient that golimumab therapy increases the risk of certain kinds of cancer, especially leukemias and lymphomas. Emphasize the importance of having follow-up visits and reporting unusual or sudden onset of signs or symptoms. Also, encourage patient to have regular skin examinations, as melanomas and Merkel cell carcinoma have occurred with golimumab therapy.
- Caution against receiving live-virus vaccines while taking golimumab; doing so may adversely affect the immune system.

- Tell patient to report lupus-like signs and symptoms that, although rare, may occur during therapy, such as chest pain that doesn't go away, joint pain, a rash on arms or cheeks that's sensitive to the sun or shortness of breath. Explain that drug may need to be discontinued if these occur.
- Advise patient to tell all healthcare providers about golimumab therapy and to tell prescriber about any OTC drugs, herbal remedies, and mineral and vitamin supplements being taken.
- Tell women of childbearing age to notify prescriber if pregnancy is suspected or known. This is because golimumab does cross the placenta during pregnancy and may increase the risk of infection for the neonate even up to 6 months after birth.
- Inform mothers who received golimumab therapy during pregnancy to monitor their infant for infections and not to have their infant receive live vaccines for 6 months following the mother's last golimumab dose during the pregnancy.
- Inform mothers wishing to breastfeed their infant to discuss this with prescriber before doing so.

## granisetron

**Sancuso, Sustol**

## granisetron hydrochloride

### **Class and Category**

*Pharmacologic class:* Serotonin blocker (5-HT<sub>3</sub> receptor antagonist)

*Therapeutic class:* Antiemetic

### **Indications and Dosages**

- *To prevent nausea and vomiting caused by emetogenic chemotherapy, including high-dose cisplatin*

## **ORAL SOLUTION, TABLETS**

**Adults.** 1 mg up to 1 hr before chemotherapy, repeated 12 hr later. Or, 2 mg up to 1 hr before chemotherapy.

## **I.V. INFUSION, I.V. INJECTION**

**Adults and children ages 2 and over.** 10 mcg/kg diluted and infused over 5 min, starting 30 min before chemotherapy; or 10 mcg/kg undiluted and given over 30 sec, starting 30 min before chemotherapy.

- *To prevent nausea and vomiting associated with moderately and/or highly emetogenic chemotherapy regimens of up to 5 consecutive days duration*

## **TRANSDERMAL (SANCUSO)**

**Adults.** 3.1 mg/24 hr patch applied to upper outer arm 24 to 48 hr before chemotherapy and worn up to 7 days. Patch removed no sooner than 24 hr after chemotherapy is completed.

- *As adjunct with other antiemetics to prevent acute and delayed nausea and vomiting associated with initial and repeat course of moderately emetogenic chemotherapy or anthracycline and cyclophosphamide combination chemotherapy regimens*

## **E. R. SUBCUTANEOUS INJECTION (SUSTOL)**

**Adults.** 10 mg in combination with dexamethasone at least 30 min before chemotherapy on day 1. *Maximum:* 10 mg once every 7 days.

***DOSAGE ADJUSTMENT*** For patients with a creatinine clearance of between 30 to 59 ml/min, Sustol brand dosage interval increased to once every 14 days.

- *To prevent nausea and vomiting caused by radiation therapy, including fractionated abdominal radiation and total body irradiation*

## **ORAL SOLUTION, TABLETS**

**Adults.** 2 mg daily given 1 hr before radiation therapy.

## **Mechanism of Action**

Has a high affinity for serotonin receptors along vagal nerve endings in intestines. Because of this affinity, granisetron prevents nausea and vomiting that usually result when serotonin is released by damaged enterochromaffin cells.

## **Incompatibilities**

Don't mix granisetron in same solution as other drugs.

## **Contraindications**

Hypersensitivity to granisetron, its components, or any other 5-HT<sub>3</sub> receptor antagonists

## **Interactions**

### **DRUGS**

*drugs that prolong the QT interval:* Increased risk of QT-interval prolongation

*serotonin and nonadrenaline reuptake inhibitors (SNRIs), serotonin reuptake inhibitors (SSRIs): Increased risk of serotonin syndrome*

## Adverse Reactions

**CNS:** Asthenia, chills, CNS stimulation, drowsiness, fever, headache, insomnia, **serotonin syndrome**, somnolence

**CV:** **Bradycardia**, chest pain, hypertension, palpitations, **prolonged QT interval**, **sick sinus syndrome**

**EENT:** Taste perversion

**GI:** Abdominal pain, anorexia, constipation, diarrhea, elevated liver enzymes, gastric distention, nausea, progressive ileus, vomiting

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**SKIN:** Alopecia, reactions at patch application site (burn, discoloration, irritation, pruritus, rash, redness, vesicles, urticaria)

**Other:** **Anaphylaxis**; subcutaneous injection-site reactions such as bleeding, bruising, hematomas, infections, nodules, pain, or tenderness

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with arrhythmias or cardiac conduction disorders because granisetron may prolong QT interval. Patients especially at risk include those with cardiac disease or electrolyte abnormalities and those receiving cardiotoxic chemotherapy or therapy with another drug that prolongs QT interval.
- For use with chemotherapy, know that drug prescribed for intravenous administration may be given diluted or undiluted. Dilute I.V. preparation of granisetron with normal saline solution or D<sub>5</sub>W to total volume of 20 to 50 ml. Mixture may be stored up to 24 hours. Use only on days when chemotherapy is given.
- Apply transdermal patch to patient's upper outer arm 24 to 48 hours before chemotherapy, and don't remove it until at least 24 hours after chemotherapy is completed.
- Know that the brand, Sustol, is the only granisetron that can be administered subcutaneously and comes as a refrigerated kit. Do not substitute nonkit components for any of the components from the kit. Remove kit at least 60 minutes prior to administration. Unpack the kit to allow the syringe containing the drug as well as all other contents to warm to room temperature. Activate one of the syringe warming pouches, and wrap the warming pouch around the syringe containing the drug for 5 to 6 minutes. Inspect the syringe containing the drug prior to administration for particulate matter and discoloration. Know that the syringe is amber-colored glass. Do not use if particulate matter or discoloration is seen, the tip cap is missing or has been tampered with, or if the Luer fitting is missing or dislodged.
- To administer granisetron (Sustol brand) subcutaneously, inject into abdomen at least one inch away from the umbilicus or into the back of the upper arm. Avoid injecting drug into areas that are burned, hardened, inflamed, swollen, or otherwise compromised. A topical anesthetic may be applied to the injection site prior to administration. Inject as a slow, sustained injection that may take up to 30 seconds. Know that pressing the plunger harder will not expel the drug faster.
- Be prepared to administer dexamethasone when giving granisetron subcutaneously (Sustol brand). For patients who are receiving moderately emetogenic chemotherapy, expect to administer 8 mg of dexamethasone

intravenously on day 1. For patients receiving anthracycline and cyclophosphamide combination chemotherapy, expect to give 20 mg of dexamethasone intravenously on day 1, followed by 8 mg of dexamethasone twice a day on days 2, 3, and 4.

- Be aware that if Sustol brand is used with an NK<sub>1</sub> receptor antagonist, the dosage for dexamethasone may be different. Check the prescribing information for the NK<sub>1</sub> receptor antagonist for recommended dexamethasone dosage.
- Assess patient receiving subcutaneous granisetron for injection-site reactions following administration. Know that some of the reactions, such as bruising, hematoma, and infection, may develop up to 2 weeks or more after the injection. Monitor patients receiving anticoagulants or antiplatelet agents closely, as bruising or hematoma formation may be more severe. When administering drug again and an injection-site reaction is still present from a previous injection, administer the drug at a site away from the affected area.

**WARNING** Monitor patient for serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking tremor, twitching or uncontrolled excitement behavior.

- Monitor patient for hypersensitivity reactions. Know that because the Sustol brand has extended-release properties, a reaction may not occur until 7 days or longer following administration and may take longer to resolve.
- Monitor patient for persistent or severe gastrointestinal effects such as constipation, gastric distention, or progressive ileus that may become severe and require hospitalization. Monitor patient closely, especially if patient is also receiving opioid medications. Consult with prescriber about using a bowel regimen, if needed. Know that the drug may mask gastric distention and/or a progressive ileus, especially in patients with recent abdominal surgery. Assess patient for decreased bowel sounds regularly.

## PATIENT TEACHING

- Inform patient that granisetron is given I.V., orally, subcutaneously, or by patch before chemotherapy to help prevent nausea.

- Instruct patient to take granisetron tablet without food to avoid reducing drug bioavailability.
- Review signs and symptoms of an allergic reaction. Tell patient to seek immediate emergency care if present. Inform patient receiving drug subcutaneously to watch for allergic reactions for 7 days or longer because drug may be present in his body for up to 7 days following administration.
- Inform patient receiving drug subcutaneously about possible injection-site reactions that can occur and that these reactions may occur up to 2 weeks or more after the injection. Instruct patient to seek immediate medical care if bleeding occurs and is severe or lasts for longer than one day or the site looks infected. Tell him to notify prescriber if he experiences bruising, hematoma, persistent nodule at the injection site, or pain or tenderness severe enough to interfere with activities of daily living or for him to take pain medication.
- Advise patient to report constipation, fever, severe diarrhea, or severe headache. Also caution about possible drowsiness.
- Advise patient wearing granisetron patch to cover it with clothing if there's a risk of exposure to sunlight. Tell patient to continue covering application site with clothing for 10 days after removal of patch. Also, tell patient not to put a heating pad over or in vicinity of the patch.

**WARNING** Instruct patient to seek immediate medical attention if the following symptoms occur: autonomic instability, changes in mental status, or neuromuscular symptoms, with or without gastrointestinal symptoms.

## guselkumab

### Tremfya

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antipsoriatic

## Indications and Dosages

- *To treat moderate to severe plaque psoriasis in patients who are candidates for systemic therapy or phototherapy*

### SUBCUTANEOUS INJECTION

**Adults.** 100 mg at wk 0, wk 4, and every 8 wks thereafter.

## Mechanism of Action

Selectively binds to the p19 subunit of interleukin 23 (IL-23) and inhibits its interaction with the IL-23 receptor, which prevents the release of proinflammatory chemokines and cytokines.

## Contraindications

Hypersensitivity to guselkumab or its components

## Interactions

### DRUGS

*CYP450 substrates:* Possibly decreased effectiveness of these drugs

*live vaccines:* Possible decreased response to vaccine

## Adverse Reactions

**CNS:** Headache, migraine

**EENT:** Nasopharyngitis, oral herpes, pharyngitis

**GI:** Diarrhea, elevated liver enzymes, gastroenteritis

**GU:** Genital herpes

**MS:** Arthralgia

**RESP:** Upper respiratory infections

**SKIN:** Rash, tinea infections, urticaria

**Other:** Antibody formation to guselkumab; candida infections; herpes simplex infections; **hypersensitivity reactions** (**angioedema**, chest or **throat tightness**, **difficulty breathing**, hives, rash), injection-site reactions of bruising, discoloration, edema, erythema, hematoma, hemorrhage, induration, inflammation, pain, pruritus, swelling, urticaria

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, human IgG antibodies are known to cross the placental barrier and therefore may be transmitted to the fetus.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Assess patient for tuberculosis before guselkumab therapy is begun. Expect treatment for latent tuberculosis to be given prior to starting guselkumab therapy.
- Remove prefilled syringe from refrigerator and allow to warm to room temperature before administering drug. Do not inject into any area that is bruised, hard, red, scaly, tender, thick, or affected by psoriasis.
- Know that all age-appropriate immunizations should be done before guselkumab therapy begins.
- Monitor patient for infections, as guselkumab increases risk. Institute infection precautions. Be aware that if infection occurs and is severe or does not respond to appropriate treatment, guselkumab will probably be discontinued.

## **PATIENT TEACHING**

- Instruct patient on how to administer a subcutaneous injection. Tell patient to remove prefilled syringe or single-dose One-Press patient-controlled injector from refrigerator and allow to warm to room temperature, keeping needle cap in place until ready to administer the injection. Tell him to inject the full amount of solution in the prefilled syringe or injector. Warn patient not to inject into an area where the skin is bruised, hard, scaly, tender, thick, or affected by psoriasis.
- Review how to properly dispose of used needles and syringes.
- Tell patient to take a missed dose as soon as he remembers and then take the next dose at the scheduled time.
- Urge patient that if an allergic reaction occurs to stop taking drug and seek immediate emergency care as reactions can become serious enough to warrant hospitalization.
- Review infection prevention practices with patient. Emphasize importance of notifying prescriber if an infection should occur.

**haloperidol**

**haloperidol decanoate**

# Haldol Decanoate, Haldol LA (CAN)

## haloperidol lactate

### Haldol Concentrate

## Class and Category

*Pharmacologic class:* Butyrophenone derivative

*Therapeutic class:* Antipsychotic

## Indications and Dosages

➤ *To treat psychosis and schizophrenia*

### ORAL SOLUTION, TABLETS

**Adults and adolescents.** *Initial:* 0.5 to 2 mg every 8 to 12 hr, increased to 3 to 5 mg every 8 to 12 hr, as needed.

*Maximum:* 30 mg daily.

**Children ages 3 to 12 weighing 15 kg (33 lb) to 40 kg (88 lb).** *Initial:* 0.25 to 0.5 mg daily in divided doses twice daily or three times daily. Increased by 0.5 mg every 5 to 7 days, as needed. *Maintenance:* 0.05 to 0.15 mg/kg/day given in 2 to 3 divided doses.

***DOSAGE ADJUSTMENT*** For debilitated or elderly patients, initial dosage reduced to 0.5 to 2 mg twice daily or three times daily, as needed.

➤ *To treat nonpsychotic behavior disorders*

### ORAL SOLUTION, TABLETS

**Children ages 3 to 12 weighing 15 kg (33 lb) to 40 kg (88 lb).** *Initial:* 0.5 mg daily in divided doses twice daily or three times daily. Increased by 0.5 mg every 5 to 7 days, if needed and then reduced to lowest effective maintenance dose. *Maintenance:* 0.05 to 0.075 mg/kg daily divided into two or three doses.

➤ *To treat Tourette's syndrome*

## **ORAL SOLUTION, TABLETS**

**Adults and adolescents.** *Initial:* 0.5 to 2 mg every 8 to 12 hr. Increased to 3 to 5 mg every 8 to 12 hr, if needed. *Maximum:* 100 mg daily in divided doses.

**Children ages 3 to 12.** *Initial:* 0.5 mg daily, increased by 0.5 mg every 5 to 7 days, as needed. *Maintenance:* 0.05 to 0.075 mg/kg daily divided into 2 or 3 doses.

➤ *To treat acutely agitated schizophrenic patient*

## **PROMPT-ACTING I.M. INJECTION**

**Adults and adolescents.** *Initial:* 2 to 5 mg, with subsequent doses every 60 min. Or, if symptoms are controlled, dose may be repeated every 4 to 8 hr. First oral dose may be given 12 to 24 hr after last parenteral dose. *Maximum:* 20 mg daily.

➤ *To provide long-term antipsychotic therapy for patients with schizophrenia who require parenteral therapy*

## **LONG-ACTING I.M. (DECANOATE) INJECTION**

**Adults.** *Initial:* 10 to 20 times the previous daily oral dose up to 100 mg. Repeated every 4 wk. *Maximum:* Initial dose should not exceed 100 mg. If conversion requires more than 100 mg as an initial dose, dose should be administered

in 2 injections, the first at the maximum of 100 mg, followed by the balance in 3 to 7 days.

**DOSAGE ADJUSTMENT** Patients who are debilitated or elderly or who are stable on low doses of oral haloperidol (up to 10 mg/day), a range of 10 to 15 times the previous daily dose in oral equivalents used for initial conversion.

Route	Onset	Peak	Duration
I.M.*	Unknown	3-4 days <sup>†</sup>	Unknown

\* For haloperidol decanoate and lactate.

† For haloperidol decanoate only; 30 to 45 min for haloperidol lactate.

## Mechanism of Action

May block postsynaptic dopamine receptors in the limbic system and increase brain turnover of dopamine, producing an antipsychotic effect.

## Contraindications

Dementia with Lewy bodies, hypersensitivity to haloperidol or its components, Parkinson's disease, severe toxic CNS comatose states or depression

## Interactions

### DRUGS

*alprazolam, buspirone, chlorpromazine, fluoxetine, fluvoxamine, itraconazole, nefazodone, promethazine, quinidine, sertraline, venlafaxine*: Increased plasma haloperidol concentrations  
*anticholinergics*: Increased anticholinergic effect

*carbamazepine, rifampin*: Decreased plasma haloperidol levels

*CNS depressants such as anesthetics and opiates*:

Increased CNS depression and risk of respiratory depression and hypotension

*drugs known to prolong QT interval such as ketoconazole, paroxetine*: Possibly increased QT interval

*levodopa and other dopamine agonists*: Possibly decreased therapeutic effects of these drugs

*tricyclic antidepressants such as desipramine, imipramine*: Increased plasma concentrations of these drugs with increased risk of adverse reactions

## ACTIVITIES

*alcohol use*: Increased CNS depression and risk of hypotension and respiratory depression

## Adverse Reactions

**CNS**: Agitation, anxiety, confusion, depression, dizziness, drowsiness, dystonia, euphoria, extrapyramidal reactions that may be irreversible, **hypothermia**, insomnia, **neuroleptic malignant syndrome**, opisthotonus, Parkinsonism, restlessness, **seizures**, slurred speech, somnolence, tremor, vertigo

**CV**: **Cardiac arrest**, edema, **extrasystoles**, hypertension, hypersensitivity vasculitis, orthostatic hypotension, **QT-interval prolongation**, **ventricular arrhythmias**, tachycardia, **torsades de pointes**

**EENT**: Blurred vision, dry mouth, increased salivation (all drug forms), **laryngeal edema**, **laryngospasm**, nystagmus, oculogyric crisis, stomatitis (oral solution)

**ENDO:** Breast discomfort and engorgement, galactorrhea, gynecomastia, hyperprolactinemia, inappropriate antidiuretic hormone secretion

**GI:** **Acute hepatic failure**, cholestasis, constipation, elevated liver enzymes, **hepatitis**, jaundice, nausea, vomiting

**GU:** Decreased or loss of libido, difficult ejaculation, impotence, menstrual irregularities, priapism, urinary retention

**HEME:** **Agranulocytosis**, anemia, leukocytosis, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Muscle rigidity or twitching, **rhabdomyolysis**, torticollis, trismus

**RESP:** **Bronchospasm**, dyspnea

**SKIN:** Acneiform skin reactions, diaphoresis, **exfoliative dermatitis**, photosensitivity, pruritis, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **heatstroke**, **hypersensitivity reactions**, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm with a potential increase risk for limb malformations when given during the first trimester of pregnancy.
- Neonates exposed to antipsychotic drugs such as haloperidol during the third trimester of pregnancy are at risk for extrapyramidal and/or withdrawal symptoms at birth.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

## Nursing Considerations

- Be aware that haloperidol shouldn't be used to treat dementia-related psychosis in the elderly because of an increased mortality risk.
- Use haloperidol cautiously in patients with a history of prolonged QT interval, patients with uncorrected electrolyte disturbances, and patients receiving Class IA or III antiarrhythmics because of an increased risk of prolonged QT interval. Monitor elderly patients closely because they may have an increased risk of prolonged QT interval.
- Be aware that haloperidol concentrations may increase in hepatically impaired patients. Monitor closely for adverse reactions.
- Dilute oral solution with a beverage, such as apple, orange, or tomato juice or cola.
- Give haloperidol decanoate (long-acting form) by deep I.M. injection into gluteal muscle using Z-track technique and 21G needle. Don't give more than 3 ml per site. Expect to reach stable plasma level after third or fourth dose.
- Know that if injection solution has a slight yellow discoloration this change doesn't affect potency.
- Assess patient for fall risks, such those who are elderly and those with conditions or diseases, or taking drugs that exacerbate central nervous system adverse effects such as motor instability, orthostatic hypotension, and somnolence. Use fall precautions in patients at risk.
- Watch for tardive dyskinesia (potentially irreversible involuntary movements) in patients receiving long-term therapy, especially elderly women who take large doses.
- Monitor CBC, especially if patient has a low WBC count or history of drug-induced leukopenia or neutropenia, often during the first few months of therapy, as ordered. If WBC count drops, especially if neutrophil count drops below  $1,000/\text{mm}^3$ , expect haloperidol to be discontinued. If neutropenia is significant, also monitor patient for fever or other symptoms of infection and provide appropriate treatment, as prescribed.

- Know that if extrapyramidal reactions occur during the first few days of treatment, dosage should be reduced as prescribed. If symptoms persist, drug may be discontinued. Dystonia also may occur during first few days of treatment, especially in patients receiving higher doses and in males and younger age-groups. Notify prescriber.
- Avoid stopping haloperidol abruptly unless severe adverse reactions occur because withdrawal emergent dyskinesia may occur.
- Monitor for signs of neuroleptic malignant syndrome, a rare but possibly fatal disorder linked to antipsychotic drugs. Signs include altered mental status, arrhythmias, fever, and muscle rigidity.

**WARNING** Know that QT-interval prolongation, sudden death, and torsades de pointes, although uncommon, may occur in patients receiving haloperidol despite the lack of such predisposing factors.

## **PATIENT TEACHING**

- Advise patient to take haloperidol exactly as prescribed and not to stop abruptly because withdrawal symptoms may occur.
- Instruct patient to dilute liquid form with cola or juice before taking it to prevent oral mucosal irritation.
- Caution patient to avoid skin contact with oral solution because it may cause a rash.
- Advise patient to take tablets with food or a full glass of milk or water to reduce GI distress.
- Instruct patient to consume adequate fluids and to take precautions against heatstroke.
- Urge patient not to drink alcohol during therapy.
- Caution patient to avoid driving and other hazardous activities if sedation occurs. Also warn patient to take measures to avoid falls because of adverse effects.
- Instruct patient to report repetitive movements, tremor, and vision changes.

# heparin sodium

**Hepalean (CAN), Heparin Leo (CAN),  
Heparin Lock Flush, Heparin  
Sodium Injection**

## Class and Category

*Pharmacologic class:* Anticoagulant

*Therapeutic class:* Anticoagulant

## Indications and Dosages

- *To prevent and treat peripheral arterial embolism, pulmonary embolism, thromboembolic complications associated with atrial fibrillation, venous thrombosis and its extension; to treat acute and chronic consumption coagulopathies (disseminated intravascular coagulation)*

### **FULL-DOSE I.V. INJECTION, FULL-DOSE I.V. INFUSION**

**Adults receiving continuous intravenous therapy.**

*Loading:* 5,000 units by I.V. injection followed by 20,000 to 40,000 units infused per 24 hr.

**Children age 1 year and older.** *Loading:* 75 to 100 units/kg by I.V. injection over 10 min followed by infusion of 18 to 20 units/kg/hr.

**Infants ages 2 months to one year.** *Loading:* 75 to 100 units/kg by I.V. injection given over 10 min followed by

infusion of 25 to 30 units/kg/hr.

**Infants less than 2 months.** *Loading:* 75 to 100 mg/kg by I.V. injection given over 10 min followed by individualized infusion with average of 28 units/kg/hr.

**Adults receiving intermittent intravenous therapy.**

*Loading:* 10,000 units followed by 5,000 to 10,000 units every 4 to 6 hr.

## **FULL-DOSE SUBCUTANEOUS INJECTION**

**Adults.** *Loading:* 333 units/kg followed by 250 units/kg every 12 hr.

➤ *To prevent postoperative thromboembolism*

## **LOW-DOSE SUBCUTANEOUS INJECTION**

**Adults.** 5,000 units 2 hr before surgery and then 5,000 units every 8 to 12 hr for 7 days or until patient is fully ambulatory.

➤ *To prevent clots in patients undergoing cardiovascular surgery*

## **I.V. INFUSION OR INJECTION**

**Adults.** 300 units/kg for procedures that last less than 60 min; 400 units/kg for procedures that last longer than 60 min. *Minimum:* 150 units/kg for initial dose.

➤ *To provide anticoagulation with blood transfusions*

## **I.V. INFUSION**

**Adults.** 400 to 600 units/100 ml of whole blood.

➤ *To provide anticoagulation with extracorporeal dialysis*

## **I.V. INFUSION, I.V. INJECTION**

**Adults.** *Loading:* 25 to 30 units/kg by I.V. injection followed by infusion of 1,500 to 2,000 units/hr.

➤ *To maintain heparin lock patency*

## I.V. INJECTION

**Adults.** 10 to 100 units/ml heparin flush solution (enough to fill device) after each use of device.

**DOSAGE ADJUSTMENT** Dosage possibly decreased in patients over 60 years of age, especially women, because of an increased risk of bleeding.

Route	Onset	Peak	Duration
I.V.	Immediate	Minutes	Unknown
SubQ	20-60 min	Unknown	Unknown

## Mechanism of Action

Binds with antithrombin III, enhancing antithrombin III's inactivation of the coagulation enzymes thrombin (factor IIa) and factors Xa and XIa. At low doses, heparin inhibits factor Xa and prevents conversion of prothrombin to thrombin. Thrombin is needed for conversion of fibrinogen to fibrin; without fibrin, clots can't form. At high doses, heparin inactivates thrombin, preventing fibrin formation and existing clot extension.

## Incompatibilities

Don't mix heparin with any other drug unless you have an order to do so and have checked with pharmacist. Heparin is incompatible with many drugs and solutions, especially ones that contain a phosphate buffer, sodium bicarbonate, or sodium oxalate.

# Contraindications

Breastfeeding, infants, neonates, or pregnant woman (heparin sodium injection, USP, preserved with benzyl alcohol); history of heparin-induced thrombocytopenia or heparin-induced thrombocytopenia and thrombosis, or thrombocytopenia with pentosan polysulfate; hypersensitivity to heparin, pork, or its components; inability to monitor coagulation parameters when full-dose heparin is used; uncontrolled active bleeding, except in disseminated intravascular coagulation (DIC)

# Interactions

## DRUGS

*antihistamines, digoxin, nicotine, tetracyclines*: Decreased anticoagulant effect of heparin

*antithrombin III (human)*: Increased risk of bleeding

*aspirin, dextran, dipyridamole, glycoprotein IIb/IIIa*

*antagonists, hydroxychloroquine, NSAIDs, phenylbutazone,*

*platelet aggregation inhibitors, thienopyridines*: Increased platelet inhibition and risk of bleeding

*dicumarol, warfarin*: Possibly invalid prothrombin time if blood drawn sooner than 5 hours after last intravenous dose or 24 hours after last subcutaneous dose of heparin

*ethacrynic acid, glucocorticoids, salicylates*

## ACTIVITIES

*smoking*: Decreased anticoagulant effect

# Adverse Reactions

**CNS:** Chills, dizziness, fever, headache, peripheral neuropathy

**CV:** Chest pain, rebound hyperlipemia, **thrombosis**

**EENT:** Epistaxis, gingival bleeding, rhinitis

**ENDO:** **Adrenal hemorrhage causing acute adrenal insufficiency**

**GI:** Abdominal distention and pain, elevated liver enzymes, **hematemesis, melena**, nausea, **retroperitoneal hemorrhage**, vomiting

**GU:** Hematuria, hypermenorrhea, **ovarian hemorrhage**, priapism

**HEME:** **Delayed onset of heparin-induced thrombocytopenia**, easy bruising, **excessive bleeding from wounds, hemorrhage, heparin-induced thrombocytopenia, heparin-induced thrombocytopenia and thrombosis, thrombocytopenia**

**MS:** Back pain, myalgia, osteoporosis (long term use of high doses)

**RESP:** **Asthma**, dyspnea, wheezing

**SKIN:** Alopecia, cutaneous necrosis following subcutaneous injection, cyanosis, petechiae, pruritus, urticaria

**Other:** **Anaphylaxis; heparin resistance**; histamine-like reactions at injection site, including necrosis of the skin; **hypersensitivity reactions**; subcutaneous deep injection-site hematoma, irritation, pain, redness, and ulceration

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk but is unlikely due to its large molecular weight.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that heparin sodium injection, USP (porcine), preserved with benzyl alcohol, should not be given to infants, neonates, pregnant women, or women who are breastfeeding because benzyl alcohol has been associated with serious adverse events and death, especially in pediatric patients. Instead, a preservative-free heparin sodium solution should be used with these patients. Various heparin products contain the preservative benzyl alcohol, which isn't recommended for children under age 1 month because it may cause gasping syndrome, which may be fatal.
- Use heparin cautiously in alcoholics; menstruating women; patients over age 60, especially women; and patients with conditions that increase risk of hemorrhage, such as certain cardiovascular conditions (severe hypertension, subacute bacterial endocarditis), gastrointestinal conditions (continuous tube drainage of small intestine or stomach, ulcerative lesions), hematologic conditions that increase risk of bleeding (hemophilia, thrombocytopenia, some vascular purpuras), liver disease with impaired hemostasis, presence of hereditary antithrombin III deficiency in patients receiving concurrent antithrombin III therapy, or presence of indwelling catheters, severe renal disease, and during or immediately following major surgery (especially involving the brain, eye, or spinal cord) or following spinal anesthesia or spinal tap. Also use cautiously in patients with a history of allergies or asthma.
- Read heparin label carefully. Revision has been made to state the strength of the entire container of heparin, followed by how much heparin is in 1 ml. This was done to eliminate the need to calculate the total amount of heparin in a product containing more than 1 ml, thereby reducing the risk of miscalculations that could result in medication errors.

**WARNING** Give heparin only by subcutaneous or I.V. route; I.M. use causes hematoma, irritation, and pain.

- Avoid injecting any drugs by I.M. route during heparin therapy, to decrease risk of bleeding and hematoma.

**WARNING** Don't use heparin sodium injection as a catheter-lock flush because fatal errors have occurred in children when 1-ml heparin sodium injection vials were confused with 1-ml catheter-lock flush vials. Always examine vial labels closely to ensure correct product is being used.

- Be aware that pediatric dosing is not achievable with the prefilled syringe. Another heparin product should be used when administering heparin to children to ensure an accurate dose.
- Administer subcutaneous heparin into anterior abdominal wall, above the iliac crest, and 5 cm (2 inches) or more away from the umbilicus. To minimize subcutaneous tissue trauma, lift adipose tissue away from deep tissues; don't aspirate for blood before injecting drug; don't move needle while injecting drug; and don't massage injection site before or after injection. Apply gentle pressure to the site after withdrawing needle.
- Alternate injection sites, and watch for signs of bleeding and hematoma.
- To prepare heparin for continuous infusion, invert container at least six times to prevent drug from pooling. Anticipate slight discoloration of prepared solution; this doesn't indicate a change in potency.
- Expect to adjust the heparin dose based on frequent blood coagulation tests, as ordered, when patient is receiving a full dose heparin regimen.
- During continuous I.V. therapy, expect to obtain APTT after 8 hours of therapy. Use the arm opposite the infusion site.
- For intermittent I.V. therapy, expect to adjust dose based on coagulation test results performed 30 minutes earlier. Therapeutic range is typically 1.5 to 2.5 times the control.
- Expect to periodically check patient's hematocrit and platelet count during the entire course of heparin therapy, regardless of route of administration.

**WARNING** Know that bleeding is a major adverse effect of heparin therapy. Take safety precautions to prevent bleeding, such as having patient use a soft-bristled

toothbrush and an electric razor. Bleeding may occur at any site and also may indicate an underlying problem, such as GI or urinary tract bleeding. Other sites of bleeding that could be fatal and require immediate attention include adrenal, ovarian, and retroperitoneal hemorrhage.

- Be aware that heparin-induced thrombocytopenia (HIT) can occur in patients exposed to heparin, including delayed onset, and is due to the development of antibodies to a platelet factor 4-heparin complex. It may progress to the development of arterial and venous thromboses. Monitor blood test results, and observe for signs of bleeding, such as ecchymosis, epistaxis, hematemesis, hematuria, melena, and petechiae. Thrombocytopenia of any degree can occur 2 to 20 days following the onset of heparin therapy, so patient should be monitored closely. If platelet count drops below  $100,000/\text{mm}^3$  or recurrent thrombosis develops, notify prescriber and expect heparin to be discontinued.
- Be aware that heparin resistance may occur, especially in patients with antithrombin III deficiency, cancer, fever, infections with thrombosing tendencies, MI, thrombophlebitis, or thrombosis and postsurgery. Monitor coagulation tests closely in these patients and expect an adjustment in the heparin dose, as needed.
- Make sure all healthcare providers know that patient is receiving heparin.
- Keep protamine sulfate on hand to use as an antidote for heparin. Be aware that each milligram of protamine sulfate neutralizes 100 units of heparin.
- Be aware that prescriber may order oral anticoagulants before discontinuing heparin to avoid increased coagulation caused by heparin withdrawal. Heparin may be discontinued when full therapeutic effect of oral anticoagulant is achieved.
- Know that women over age 60 have highest risk of hemorrhage during therapy.
- Watch closely if patient is receiving heparin therapy and nitroglycerin I.V. because PTT may decrease and then rebound after nitroglycerin is discontinued. Monitor PTT closely, and be prepared to adjust heparin dose, as prescribed.

**WARNING** Know that delayed-onset, heparin-induced thrombocytopenia may occur several weeks after

heparin is discontinued and may progress to heparin-induced thrombocytopenia thrombosis, causing arterial and venous thromboses, including thrombus formation on a prosthetic cardiac valve.

## **PATIENT TEACHING**

- Explain that heparin can't be taken orally.
- Inform patient about increased risk of bleeding; urge her to avoid injuries and to use a soft-bristled toothbrush and an electric razor.
- Urge patient to report any abnormal sign or symptom to prescriber, even weeks after heparin has been discontinued, because of the potential for delayed adverse reactions.
- Advise patient to avoid drugs that interact with heparin, such as aspirin and ibuprofen.
- Instruct patient and family to watch for and report abdominal or lower back pain, black stools, bleeding gums, bloody urine, excessive menstrual bleeding, nosebleeds, and severe headaches. Also tell patient to report any persistent, severe, or unusual signs and symptoms to prescriber immediately. Alert patient receiving heparin subcutaneously that necrosis of the skin has been reported following subcutaneous administration of heparin and to alert prescriber if any abnormalities occur at injection sites.
- Explain that temporary hair loss may occur.
- Advise patient to wear or carry appropriate medical identification.

## **hydralazine hydrochloride**

**Apresoline (CAN)**

## **Class and Category**

*Pharmacologic class:* Vasodilator

*Therapeutic class: Antihypertensive*

## Indications and Dosages

- *To manage essential hypertension, alone or with other antihypertensives*

### **TABLETS**

**Adults.** *Initial:* 10 mg four times daily for first 2 to 4 days and then increased to 25 mg four times daily for remainder of first wk. Further increased to 50 mg four times daily beginning wk 2 and thereafter. *Maintenance:* 50 to 200 mg daily in divided doses. *Maximum:* 200 mg daily.

**Children.** *Initial:* 0.75 to 1 mg/kg daily in divided doses twice daily to four times daily. Increased gradually over 3 to 4 wk. *Maximum:* 7.5 mg/kg daily not to exceed 200 mg/day for children older than 1 and 5 mg/kg/day for infants less than 1 year of age, not to exceed 20 mg/dose or 200 mg daily.

- *To manage severe essential hypertension when drug can't be taken orally or when need to reduce blood pressure is urgent*

### **I.V. OR I.M. INJECTION**

**Adults.** 20 to 40 mg, repeated as needed. I.V. injection given rapidly over 1 min.

**Children older than 1 year.** *Initial:* 0.1 to 0.2 mg/kg every 4 to 6 hr, as needed, increased to 1.7 to 3.5 mg/kg/day in divided doses. I.V. given slowly at a rate of no more than 5 mg/min. *Maximum:* 20 mg/dose or 2 mg/kg/every 3 to 6 hr with cumulative dose not to exceed 9 mg/kg.

**Children 3 months to 1 year.** *Initial:* 0.1 to 0.5 mg/kg/dose given only I.V. every 6 to 8 hr. I.V. given slowly at a rate of no more than 5 mg/min. *Maximum:* 2 mg/kg every 6 hr.

***DOSAGE ADJUSTMENT*** For adults with marked renal impairment, dosage may need to be reduced.

Route	Onset	Peak	Duration
P.O.	20-30 min	1-2 hr	2-4 hr
I.V.	5-20 min	10-80 min	2-6 hr
I.M.	10-30 min	1 hr	2-6 hr

## Mechanism of Action

May act in a manner that resembles organic nitrates and sodium nitroprusside, except that hydralazine is selective for arteries. It:

- exerts a direct vasodilating effect on vascular smooth muscle
- interferes with calcium movement in vascular smooth muscle by altering cellular calcium metabolism
- dilates arteries, not veins, which minimizes orthostatic hypotension and increases cardiac output and cerebral blood flow
- causes reflex autonomic response that increases, cardiac output, heart rate, and left ventricular ejection fraction
- has a positive inotropic effect on the heart.

## Incompatibilities

Don't mix hydralazine in I.V. infusion solutions.

## Contraindications

Coronary artery disease, hypersensitivity to hydralazine or its components, mitral valvular rheumatic heart disease

## Interactions

### DRUGS

*diazoxide, MAO inhibitors, other antihypertensives:* Risk of severe hypotension

*NSAIDs:* Decreased hydralazine effects

### FOODS

*all foods:* Possibly increased bioavailability of hydralazine

## Adverse Reactions

**CNS:** Chills, fever, headache, peripheral neuritis

**CV:** Angina, edema, orthostatic hypotension, palpitations, tachycardia

**EENT:** Lacrimation, nasal congestion

**GI:** Anorexia, constipation, diarrhea, nausea, vomiting

**RESP:** Dyspnea

**SKIN:** Blisters, flushing, pruritus, rash, urticaria

**Other:** Lupus-like symptoms, especially with high doses; lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Monitor ANA titer, CBC, and lupus erythematosus cell preparation before therapy and periodically as ordered during long-term treatment.
- Anticipate that drug may change color in solution. Consult pharmacist if color changes.
- Be aware that hydralazine may change color when exposed to a metal filter.
- Give tablets with food to increase bioavailability.
- Monitor blood pressure and pulse rate regularly and weigh patient daily during therapy.
- Check blood pressure with patient in lying, sitting, and standing positions, and watch for signs of orthostatic hypotension. Expect orthostatic hypotension to be most common in the morning, during hot weather, and with exercise.

**WARNING** Expect to discontinue drug immediately if patient has lupus-like symptoms, such as arthralgia, fever, myalgia, pharyngitis, and splenomegaly.

- Expect prescriber to withdraw hydralazine gradually to avoid a rapid increase in blood pressure.
- Expect to treat peripheral neuritis with pyridoxine.

## PATIENT TEACHING

- Instruct patient to take hydralazine tablets with food.

- Advise patient to change position slowly, especially in the morning. Caution that hot showers may increase hypotension.
- Instruct patient to immediately notify prescriber about fever, joint and muscle aches, and sore throat.
- Urge patient to report numbness and tingling in limbs, which may require treatment with another drug.
- Caution patient against stopping drug abruptly because doing so may cause severe hypertension.

## hydrochlorothiazide

**Microzide, Oretic, Urozide (CAN)**

### Class and Category

*Pharmacologic class:* Thiazide diuretic

*Therapeutic class:* Diuretic

### Indications and Dosages

➤ *To manage hypertension*

#### CAPSULES

**Adults. Initial:** 12.5 to 25 mg daily increased, as needed, to 50 mg daily given as a single dose or 2 divided doses.

**Maximum:** 50 mg daily.

#### TABLETS

**Adults. Initial:** 25 mg daily, increased to 50 mg daily, as needed, and given as a single dose or in divided doses

twice daily.

**Children age 6 months and over.** 1 to 2 mg/kg daily as a single dose or in divided doses twice daily. *Maximum:* 37.5 mg daily for children 6 months to 2 years; 100 mg daily for children age 2 to 12.

**Infants under age 6 months.** Up to 3 mg/kg daily in 2 divided doses.

- *As adjunct to treat edema caused by cirrhosis, corticosteroids, estrogen, heart failure, or renal disorders*

## TABLETS

**Adults.** 25 to 100 mg once or twice daily.

**Children age 6 months and over.** 1 to 2 mg/kg daily as a single dose or in divided doses twice daily. *Maximum:* 37.5 mg daily for children 6 months to 2 years; 100 mg daily for children age 2 to 12.

**Infants under age 6 months.** Up to 3 mg/kg daily in 2 divided doses.

Route	Onset	Peak	Duration
P.O.	2 hr	4 hr	6-12 hr

## Contraindications

Anuria; hypersensitivity to hydrochlorothiazide, other thiazides, sulfonamide derivatives, or their components

## Mechanism of Action

A thiazide diuretic, hydrochlorothiazide promotes movement of sodium ( $\text{Na}^+$ ), chloride ( $\text{Cl}^-$ ), and water ( $\text{H}_2\text{O}$ ) from blood in peritubular capillaries into

nephron's distal convoluted tubule, as shown. Initially, it may decrease cardiac output, extracellular fluid volume, or plasma volume, which helps explain blood pressure reduction. It also may reduce blood pressure by direct arterial dilation. After several weeks, cardiac output, extracellular fluid volume, and plasma volume return to normal, and peripheral vascular resistance remains decreased.

## Interactions

### DRUGS

*ACTH, corticosteroids:* Increased electrolyte depletion, especially potassium  
*antihypertensives:* Increased antihypertensive effects  
*barbiturates, opioids:* Possibly orthostatic hypotension  
*cholestyramine, colestipol:* Reduced GI absorption of hydrochlorothiazide  
*insulin, oral antidiabetic drugs:* Possibly increased blood glucose level  
*lithium:* Decreased lithium clearance, increased risk of lithium toxicity  
*nondepolarizing skeletal muscle relaxants:* Possibly increased response to muscle relaxants  
*NSAIDs:* Decreased diuretic effect of hydrochlorothiazide, increased risk of renal failure

## **ACTIVITIES**

*alcohol use:* Possibly orthostatic hypotension

## **Adverse Reactions**

**CNS:** Asthenia, dizziness, fever, headache, insomnia, paresthesia, restlessness, vertigo, weakness

**CV:** Elevated cholesterol and triglycerides levels, **hypotension**, orthostatic hypotension, vasculitis

**EENT:** Acute myopia, acute angle-closure glaucoma, blurred vision, dry mouth

**ENDO:** Hyperglycemia

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Decreased libido, impotence, interstitial nephritis, nocturia, polyuria, **renal failure**

**HEME:** Agranulocytosis, aplastic anemia, bone marrow failure, hemolytic anemia, leukopenia, neutropenia, thrombocytopenia

**MS:** Muscle spasms and weakness

**RESP:** Pneumonitis, pulmonary edema

**SKIN:** Alopecia, cutaneous vasculitis, erythema multiforme, exfoliative dermatitis, photosensitivity, purpura, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, dehydration, hypercalcemia, hyperuricemia, hyponatremia, hypokalemia, hypomagnesemia, hypovolemia, metabolic alkalosis, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but because it crosses the placental barrier, there is a risk of fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Give hydrochlorothiazide in the morning and early evening to avoid nocturia.
- Monitor blood pressure, daily weight, fluid intake and output, and serum levels of electrolytes, especially potassium.
- Assess for evidence of hypokalemia, such as muscle spasms and weakness.
- Check blood glucose level often, as ordered, in diabetic patients, and expect to increase antidiabetic dosage, as needed and prescribed.
- Know that if patient has gouty arthritis, expect increased risk of gout attacks during therapy.
- Monitor BUN and serum creatinine levels, as ordered, especially in patients with chronic kidney disease, renal artery stenosis, severe congestive heart failure, or volume depletion, because of increased risk of acute renal failure with hydrochlorothiazide therapy. Notify prescriber if serum creatinine levels become elevated, as drug may need to be withheld or discontinued.
- Monitor patient for decreased visual acuity or ocular pain, especially within hours to weeks of beginning drug therapy and in patients with a history of penicillin or sulfonamide allergy, as acute myopia and acute angle-closure glaucoma may develop. If left untreated, permanent blindness may occur. If present, notify prescriber immediately, expect to discontinue hydrochlorothiazide, and assist with prompt medical or surgical intervention, as indicated.

**WARNING** Be aware that even minor alterations in fluid and electrolyte balance may precipitate hepatic coma in patients with impaired hepatic function.

## **PATIENT TEACHING**

- Advise patient to take hydrochlorothiazide in morning and early evening to avoid awakening during the night to urinate.
- Instruct patient to take drug with food or milk if adverse GI reactions occur.
- Tell patient to weigh herself at the same time each day wearing the same amount of clothing and to notify prescriber if she gains more than 0.9 kg (2 lb) per day or 2.3 kg (5 lb) per week.

- Instruct patient to eat a diet high in potassium-rich food, including, bananas, citrus fruits, dates, and tomatoes.
- Advise patient to change position slowly to minimize effects of orthostatic hypotension.
- Urge patient to report decreased urination, muscle cramps and weakness, and unusual bleeding or bruising.

## hydrocodone bitartrate

**Hysingla ER, Vantrela ER, Zohydro ER**

### **Class, Category, and Schedule**

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

Controlled substance schedule: II

### **Indications and Dosages**

- *To manage severe pain in patients requiring continuous, around-the-clock opioid analgesia for an extended period of time and for which alternative treatment options are inadequate*

#### **E.R. CAPSULES (ZOHYDRO ER)**

**Adults who are opioid naïve or opioid nontolerant.**

*Initial:* 10 mg every 12 hr, increased, as needed, in increments of 10 mg every 12 hr every 3 to 7 days to

effective and tolerable dose. *Maximum:* 40 mg/dose or 80 mg total daily dose.

**Adults who are opioid tolerant and converting from another opioid.** Highly individualized.

**DOSAGE ADJUSTMENT** For patients with severe hepatic impairment, a single dose of 10 mg given, followed by close monitoring for respiratory depression and sedation. If single dose tolerated, 10 mg every 12 hr as needed and titrated carefully.

## **E.R. TABLETS (HYSINGLA ER)**

**Adults who are opioid naïve or opioid nontolerant.**

*Initial:* 20 mg every 24 hr, increased, as needed, in increments of 10 to 20 mg daily every 3 to 5 days to effective and tolerable dose. *Maximum:* 80 mg every 24 hr.

**Adults who are opioid tolerant and converting from another opioid.** Highly individualized.

**DOSAGE ADJUSTMENT** For patients with moderate to severe renal impairment, including end stage renal disease, or severe hepatic impairment, initial dosage reduced to 10 mg every 24 hr.

## **E.R. TABLETS (VANTRELA ER)**

**Adults who are opioid naïve or opioid nontolerant.**

*Initial:* 15 mg every 12 hr, increased to next higher dose every 3 to 7 days as needed.

**DOSAGE ADJUSTMENT** For patient with mild or moderate hepatic impairment, or moderate or severe renal impairment, including end-stage renal disease, initial dosage decreased by half.

## **Mechanism of Action**

Binds to and activates opioid receptors at sites in the periaqueductal and periventricular gray matter, the ventromedial medulla, and the spinal cord to produce pain relief.

## Contraindications

Acute or severe bronchial asthma (in an unmonitored setting or in the absence of resuscitative equipment); hypersensitivity to hydrocodone bitartrate or any of its components; known or suspected gastrointestinal obstruction, including paralytic ileus; significant respiratory depression

## Interactions

### DRUGS

*5-HT<sub>3</sub> receptor antagonists, drugs that affect the serotonin neurotransmitter system (mirtazapine, trazodone, tramadol), linezolid, methylene blue (I.V.), selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans, tryptophan:* Increased risk of serotonin syndrome

*anticholinergics:* Increased risk of urinary retention or severe constipation, which may lead to paralytic ileus

*antipsychotics, anxiolytics, benzodiazepines and other CNS depressants, general anesthetics, muscle relaxants, other opioids and sedatives/hypnotics, sedating antihistamines, tranquilizers, tricyclic antidepressants:* Increased risk of coma, hypotension, profound sedation, and severe respiratory depression

*CYP3A4 inducers:* Increased clearance of hydrocodone with decreased effectiveness

*CYP2D6 inhibitors, CYP3A4 inhibitors:* Decreased clearance of hydrocodone resulting in increased or prolonged opioid effects  
*diuretics:* Possible reduction of the effectiveness of diuretics  
*mixed agonist/antagonist analgesics such as buprenorphine, butorphanol, nalbuphine, pentazocine:* Possible reduced hydrocodone effectiveness or precipitation of withdrawal symptoms  
*MAO inhibitors:* Increased risk of serotonin syndrome or opioid toxicity  
*muscle relaxants:* Enhanced neuromuscular blocking action of skeletal muscle relaxants producing increased degree of respiratory depression

## ACTIVITIES

*alcohol use:* Possibly increased hydrocodone plasma levels with potentially fatal overdose

## Adverse Reactions

**CNS:** Anxiety, **CNS depression**, **coma**, depression, dizziness, fatigue, fever, headache, insomnia, lethargy, migraine, paresthesia, **seizures**, somnolence, syncope, tremor

**CV:** Hypercholesterolemia, **hypotension**, peripheral edema

**EENT:** Dry mouth

**ENDO:** **Adrenal insufficiency** (rare), hot flashes

**GI:** Abdominal discomfort or pain, constipation (may be severe), elevated liver enzymes, gastroesophageal reflux disease, nausea, spasm of the Sphincter of Oddi, vomiting

**GU:** Decreased libido, erectile dysfunction, impotence, infertility, lack of menstruation, UTI

**MS:** Arthralgia; back, extremity, musculoskeletal, or neck pain; muscle spasms

**RESP:** Cough, dyspnea, **respiratory depression**

**SKIN:** Pruritis, rash, sweating including night sweats

**Other:** Dehydration, **hypokalemia**, noncardiac chest pain, physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Prolonged use during pregnancy should be avoided. Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the newborn. Monitor newborn closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

# REPRODUCTION

- Chronic use of opioids may reduce fertility in females and males.

## Nursing Considerations

- Be aware that hydrocodone increases the risk of abuse, addiction, and misuse. Know that to ensure that the benefits of hydrocodone therapy outweigh the risks, a Risk Evaluation and Mitigation Strategy (REMS) is required.
- Know that hydrocodone should not be given to a patient with impaired consciousness, nor should the drug be administered on an as-needed basis.
- Be aware that opioids like hydrocodone should not be given to women during pregnancy, while in labor, or when breastfeeding, as the newborn or infant may experience neonatal opioid withdrawal syndrome (NOWS), which could be life-threatening. This syndrome may exhibit as excessive or high-pitched crying, poor feeding, rapid breathing, or trembling. If not recognized and treated appropriately, it can become life-threatening.
- Know that hydrocodone is contraindicated in children under the age of 18 when used in cold or cough preparations.
- Use extreme caution when administering hydrocodone to patients with significant chronic obstructive pulmonary disease or cor pulmonale, and in patients having a substantially decreased respiratory reserve, hypoxia, hypercapnia, or preexisting respiratory depression, especially when initiating or titrating therapy. These patients may develop respiratory depression, even with usual therapeutic doses, because hydrocodone may decrease the patient's respiratory drive to the point of apnea.
- Use hydrocodone cautiously in cachectic, debilitated or elderly patients, especially when initiating and titrating therapy, as they are at increased risk for adverse effects, especially respiratory depression.
- Be aware that opioid therapy like hydrocodone should only be used concomitantly with benzodiazepines and other CNS depressants in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of hydrocodone to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Be aware that patients who are considered opioid tolerant are those who have received for 1 week or longer, at least 8 mg of oral hydromorphone per day, 60 mg of oral morphine daily, 30 mg of oral oxycodone per day, 25 mg of oral oxymorphone per day, 25 micrograms transdermal fentanyl per hour, or an equianalgesic dose of another opioid.
- Do not administer hydrocodone to a patient wearing a transdermal fentanyl patch until the patch has been removed for 18 hours. Also know that close monitoring is especially important for a patient converting from methadone because methadone has a long half-life and tends to accumulate in the blood.

**WARNING** Be aware that hydrocodone available as an extended release formulation increases risk of overdose and death because of larger amount of drug present in this form. Also know that crushing, chewing, snorting, or injecting the contents of the Hysingla ER tablet dissolved in a liquid base will result in the uncontrolled delivery of hydrocodone and can result in overdose and death. Be aware that Zohydro ER capsules are made with a formulation that deters abuse because it forms an immediate inactive viscous gel when crushed or dissolved in liquids or solvents.

**WARNING** Monitor patient for respiratory depression, especially when initiating therapy or when increasing dosage, even when the drug has been used as prescribed and not abused or misused. Be aware that overestimating hydrocodone dose when converting patients from another opioid medication can result in fatal overdose with the first dose. To avoid this, know that it is recommended to underestimate a patient's 24-hour oral hydrocodone requirement and provide rescue medication, as needed, until the right dose is determined. Keep resuscitation equipment nearby.

- Be aware that drug can cause sleep-related breathing disorders including central sleep apnea and sleep-related hypoxemia that may require a dosage decrease, if present.

- Monitor patients closely who may be susceptible to the intracranial effects of carbon dioxide retention from respiratory depression caused by hydrocodone therapy, such as patients with head injuries or those who have a preexisting elevation in intracranial pressure.
- Monitor patients with a seizure history or disorder because hydrocodone may cause or worsen seizures.
- Monitor effectiveness of hydrocodone in relieving pain; consult prescriber as needed.
- Assess patient for constipation and provide a high-fiber diet and adequate fluid intake, if not contraindicated, because constipation can become severe.
- Monitor patient for evidence of physical dependence or abuse. Know that addiction can occur not only in those who obtain the drug illicitly but also in patients who are appropriately prescribed the drug at recommended doses. Be aware that excessive use of hydrocodone may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely.
- Notify prescriber if serious adverse reactions occur with hydrocodone therapy and expect dosage to be reduced.
- Expect to taper hydrocodone dosage gradually every 2 to 4 days when patient no longer requires therapy to prevent withdrawal symptoms in the physically dependent patient. Know that hydrocodone should not be discontinued abruptly.
- Monitor patient's vital signs closely, especially after initiating or titrating dose of hydrocodone. Know that in addition to respiratory depression, hydrocodone may cause severe hypotension, especially in patients whose blood pressure is already compromised by a depleted blood volume or after concurrent administration of drugs that decrease blood pressure.
- Be aware that concomitant use with CYP3A4 inhibitors or discontinuation of CYP3A inducers can result in a fatal overdose of hydrocodone.

**WARNING** Know that many drugs may interact with opioids like hydrocodone to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening.

Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If diagnosis is confirmed, expect to administer corticosteroids and wean patient off of hydrocodone, if possible.
- Monitor patient for decreased bowel motility in postoperative patients receiving hydrocodone, as the drug may obscure the development of acute abdominal conditions.

## **PATIENT TEACHING**

- Warn parents that children under age 18 should not receive hydrocodone when mixed with cold or cough preparations.
- Instruct patient to take drug exactly as ordered and not to adjust dosage without speaking to prescriber first. Warn patient of possibility of addiction even when taken as prescribed. Inform him that excessive or prolonged use can also lead to addiction, misuse, overdose, and possibly death.
- Inform patient that capsules and tablets should be taken whole and never chewed, crushed, or dissolved. In addition, enough water should be taken with the capsule or tablet to ensure complete swallowing immediately after placing drug in mouth.
- Warn patient to keep hydrocodone away from the reach of children, as accidental consumption of even one capsule or tablet can cause significant respiratory depression and death.
- Caution patient to avoid ingesting alcohol, including medications containing alcohol, as the combination increases the risk of overdose, respiratory depression, and death, as does taking other types of depressants, including benzodiazepines, together with hydrocodone therapy. Patient should notify all prescribers of hydrocodone use.
- Advise women of childbearing age to notify prescriber if pregnancy occurs or is suspected because a fetus exposed to hydrocodone during utero may require treatment for neonatal opioid withdrawal syndrome (NOWS) when born. Also advise women not to breastfeed while taking oxycodone.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to rise slowly from a lying or sitting position and to lie or sit down if he experiences light-headedness. If effect is frequent or severe, tell him to notify prescriber.
- Urge patient to consume plenty of fluids and high-fiber foods, if not contraindicated, to prevent constipation.
- Inform patient that long-term use of opioids like hydrocodone may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any such symptoms.
- Instruct patient to notify all prescribers of hydrocodone use.
- Advise patients to flush unused drug down the toilet or take to a proper disposal place when drug is no longer needed.

## hydrocortisone

(cortisol)

**Cortef, Cortenema, Hydrocortone**

**hydrocortisone acetate**

**Cortifoam, Hydrocortone Acetate**

**hydrocortisone cypionate**

**Cortef**

**hydrocortisone sodium  
phosphate**

# Hydrocortone Phosphate

## hydrocortisone sodium succinate

**A-hydroCort, Solu-Cortef**

### Class and Category

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Adrenocorticoid replacement, anti-inflammatory

### Indications and Dosages

- *To treat severe inflammation or acute adrenal insufficiency*

#### **TABLETS (HYDROCORTISONE, HYDROCORTISONE CYPIONATE)**

**Adults.** 20 to 240 mg daily as a single dose or in divided doses.

#### **I.V. INFUSION OR I.V., I.M., OR SUBCUTANEOUS INJECTION (HYDROCORTISONE SODIUM PHOSPHATE); I.M. INJECTION (HYDROCORTISONE)**

**Adults.** 15 (20 mg hydrocortisone) to 240 mg daily as a single dose or in divided doses. For I.V. infusion, give over

20 to 30 min. For I.V. injection, give over 30 sec to 10 min depending on dose.

***DOSAGE ADJUSTMENT*** Dosage increased to more than 240 mg daily if needed to treat acute disease.

## **I.V. INFUSION; I.V. OR I.M. INJECTION (HYDROCORTISONE SODIUM SUCCINATE)**

**Adults.** 100 to 500 mg every 2, 4, or 6 hr. For I.V. infusion, give over 20 to 30 min. For I.V. injection, give over 30 sec to 10 min depending on dose.

➤ *To treat acute exacerbations of multiple sclerosis*

## **TABLETS**

**Adults.** 200 mg daily for 1 wk followed by 80 mg every other day for 1 month.

➤ *To treat joint and tissue inflammation*

## **INTRA-ARTICULAR INJECTION (HYDROCORTISONE ACETATE)**

**Adults.** 25 to 37.5 mg injected into large joints or bursae as a single dose, or 10 to 25 mg into small joints as a single dose.

## **INTRALESIONAL INJECTION (HYDROCORTISONE ACETATE)**

**Adults.** 5 to 12.5 mg injected into tendon sheaths as a single dose, or 12.5 to 25 mg injected into ganglia as a single dose.

## **SOFT-TISSUE INJECTION (HYDROCORTISONE ACETATE)**

**Adults.** 25 to 50 mg as a single dose. Sometimes a dose of up to 75 mg is needed.

- *As adjunct to treat ulcerative proctitis of the distal portion of the rectum in patients who can't retain hydrocortisone or other corticosteroid enemas*

## RECTAL AEROSOL (HYDROCORTISONE ACETATE)

**Adult men.** Initial: 1 applicatorful once or twice daily for 2 to 3 wk; then every other day thereafter. *Maintenance:* Highly individualized.

- *To treat ulcerative colitis*

## ENEMA (HYDROCORTISONE)

**Adults.** 100 mg every night for 21 days or until condition improves.

Route	Onset	Peak	Duration
P.O. <sup>†</sup>	Unknown	1 hr	1.25-1.5 days
P.O. <sup>  </sup>	Unknown	1-2 hr	Unknown
I.V. <sup>‡§</sup>	Rapid	Unknown	Unknown
I.M. <sup>†</sup>	Unknown	4-8 hr	Unknown
I.M. <sup>‡</sup>	Rapid	1 hr	Unknown
I.M. <sup>§</sup>	Rapid	1 hr	Variable
Other*	Unknown	24-48 hr	3 days-4 wk

\* Acetate; intra-articular, intralesional, and soft-tissue injection.

† Hydrocortisone.

‡ Phosphate.

§ Succinate.

|| Cypionate.

## Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting monocyte and neutrophil accumulation at inflammation site and suppressing their bactericidal and phagocytic activity
- stabilizing lysosomal membranes
- suppressing antigen response of helper T cells and macrophages
- inhibiting synthesis of cellular mediators of inflammatory response, such as cytokines, interleukins, and prostaglandins.

## Contraindications

Hypersensitivity to hydrocortisone or its components, idiopathic thrombocytopenic purpura (I.M.), intestinal conditions prohibiting intrarectal steroids (P.R.), systemic fungal infection

## Interactions

### DRUGS

*aspirin, NSAIDs*: Increased risk of GI distress and bleeding; increased risk of salicylate toxicity with chronic high doses of aspirin

*phenobarbital, phenytoin, rifampin*: Decreased blood hydrocortisone level

*insulin, oral antidiabetic drugs*: Possibly increased blood glucose level

*ketoconazole, troleandomycin*: Decreased clearance of hydrocortisone with increased plasma levels and higher risk of adverse reactions

*oral anticoagulants*: May decrease or increase anticoagulant effect

*vaccines (live attenuated)*: Decreased antibody response and increased risk of neurologic complications

## ACTIVITIES

*alcohol use:* Increased risk of GI distress and bleeding

## Adverse Reactions

**CNS:** Ataxia, behavioral changes, depression, dizziness, epidural lipomatosis, euphoria, fatigue, headache, **increased intracranial pressure with papilledema**, insomnia, malaise, mood changes, paresthesia, **seizures**, steroid psychosis, syncope, vertigo

**CV:** **Arrhythmias**, **fat embolism**, **heart failure**, hypertension, **hypotension**, **thromboembolism**, thrombophlebitis

**EENT:** Central serous chorioretinopathy, exophthalmos, glaucoma, increased intraocular pressure, nystagmus, posterior subcapsular cataracts

**ENDO:** **Adrenal insufficiency during stress**, cushingoid symptoms (buffalo hump, central obesity, moon face, supraclavicular fat pad enlargement), diabetes mellitus, growth suppression in children, hyperglycemia, negative nitrogen balance from protein catabolism

**GI:** Abdominal distention; hiccups; increased appetite; nausea; **pancreatitis**; peptic ulcer; rectal abnormalities, such as **bleeding**, blistering, burning, itching, or pain (rectal form); ulcerative esophagitis; vomiting

**GU:** Amenorrhea, glycosuria, menstrual irregularities, perineal burning or tingling

**HEME:** Easy bruising, leukocytosis

**MS:** Arthralgia; aseptic necrosis of femoral and humeral heads; compression fractures; muscle atrophy, twitching,

or weakness; myalgia; osteoporosis; spontaneous fractures; steroid myopathy; tendon rupture

**SKIN:** Acne; altered skin pigmentation; diaphoresis; erythema; hirsutism; necrotizing vasculitis; petechiae; purpura; rash; scarring; sterile abscess; striae; subcutaneous fat atrophy; thin, fragile skin; urticaria

**Other:** **Anaphylaxis**, **hypocalcemia**, **hypokalemia**, **hypokalemic alkalosis**, impaired wound healing, masking of signs of infection, **metabolic alkalosis**, **pheochromocytoma crisis** (in presence of pheochromocytoma), suppressed skin test reaction, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug has the potential to cause fetal harm as it does cross the placental barrier.
- Infants born of mothers who have received substantial doses of corticosteroids during pregnancy must be observed for signs of adrenal insufficiency. Cataracts have also been observed in mothers undergoing long-term treatment with corticosteroids during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk and could suppress growth.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Drug may alter male fertility.

# Nursing Considerations

- Know that systemic hydrocortisone shouldn't be given to immunocompromised patients, such as those with fungal and other infections, including amebiasis, hepatitis B, tuberculosis, vaccinia, and varicella.
- Give daily dose of hydrocortisone in morning to mimic normal peak in adrenocortical secretion of corticosteroids.
- Give oral dose with food or milk to avoid GI distress.
- Don't give acetate injectable suspension by I.V. route.
- Give hydrocortisone sodium succinate as a direct I.V. injection over 30 seconds to several minutes, or as an intermittent or a continuous infusion. For infusion, dilute to 1 mg/ml or less with D<sub>5</sub>W, normal saline solution, or dextrose 5% in normal saline solution.
- Inject I.M. form deep into gluteal muscle, and rotate injection sites to prevent muscle atrophy. Subcutaneous injection may cause atrophy and sterile abscess.
- Shake foam container vigorously for 5 to 10 seconds before each use. Gently withdraw applicator plunger past the fill line on the applicator barrel while container is upright on a level surface. Administer rectal foam only with provided applicator. After each use, wash applicator, container cap, and underlying tip with warm water.
- Be aware that high-dose therapy shouldn't be given for longer than 48 hours. Be alert for depression and psychotic episodes.
- Monitor blood pressure, electrolyte levels, and weight regularly during therapy.
- Expect hydrocortisone to worsen infections or mask signs and symptoms.
- Monitor blood glucose level in diabetic patients, and increase insulin or oral antidiabetic drug dosage, as prescribed.
- Know that elderly patients are at high risk for osteoporosis during long-term therapy.
- Anticipate the possibility of acute adrenal insufficiency with stress, such as emotional upset, fever, surgery, or trauma. Increase hydrocortisone dosage, as prescribed.

**WARNING** Avoid withdrawing drug suddenly after long-term therapy because adrenal crisis can result. Expect to reduce dosage gradually and monitor response.

## **PATIENT TEACHING**

- Advise patient to take daily dose of hydrocortisone at 9 a.m.
- Instruct patient to take tablets with food or milk.
- Teach patient how to use enema form or foam, if prescribed.
- Caution patient not to stop drug abruptly without first consulting prescriber.
- Instruct patient to report early evidence of adrenal insufficiency: anorexia, difficulty breathing, dizziness, fainting, fatigue, joint pain, muscle weakness, and nausea.
- Inform patient that he may bruise easily.
- Advise patient on long-term therapy to have periodic eye examinations.
- If patient receives long-term therapy, urge him to carry or wear medical identification.
- Caution patient to avoid people with infections because drug can suppress immune system, increasing risk of infection. If patient comes into contact with chickenpox or measles, instruct him to call prescriber because he may need prophylactic care.

**hydromorphone  
hydrochloride**

**(dihydromorphinone)**

**Dilaudid, Dilaudid-HP, Exalgo**

# Class, Category, and Schedule

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

## Indications and Dosages

- *To relieve pain severe enough to require opioid treatment and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated*

### ORAL SOLUTION (DILAUDID)

**Adults.** 2.5 to 10 mg every 3 to 6 hr, as needed.

### TABLETS (DILAUDID)

**Adults.** 2 to 4 mg every 4 to 6 hr, as needed.

### I.V. INJECTION (DILAUDID)

**Adults.** 0.2 to 1 mg every 2 to 3 hr, as needed, given slowly over 2 to 3 min.

### I.M. OR SUBCUTANEOUS INJECTION (DILAUDID)

**Adults.** 1 or 2 mg every 2 to 3 hr, as needed.

### SUPPOSITORIES (DILAUDID)

**Adults.** 3 mg every 6 to 8 hr, as needed.

***DOSAGE ADJUSTMENT*** For patients with hepatic or renal impairment, initial dosage is given at 25 to 50% of normal dosage. For debilitated or elderly patients, I.V. dosage kept at 0.2 mg.

- *To treat moderate to severe pain for opioid-tolerant patients who require higher doses of opioids*

## **I.M., I.V. OR SUBCUTANEOUS INJECTION (DILAUDID-HP)**

**Adults who are not opioid-naïve.** Highly individualized and dependent on patient's previous total daily 24-hour opioid use. If I.V. route is used, give slowly over 2 to 3 min. *Usual for I.M or subcutaneous injection:* 1 to 2 mg every 2 to 3 hr, as needed, with dosage adjusted according to clinical response. *Usual for I.V. injection:* 0.2 to 1 mg every 2 to 3 hr, given slowly over at least 2 to 3 min, depending on dose.

***DOSAGE ADJUSTMENT*** For debilitated or elderly patient, I.V. injection initial dosage may be kept at 0.2 mg.

- *To manage moderate to severe pain in opioid-tolerant patients requiring continuous, around-the-clock opioid analgesia for an extended period of time and for which alternative treatment options are inadequate*

## **E.R. TABLETS (EXALGO)**

**Adults.** Highly individualized and dependent on patient's previous total 24-hour opioid use and risk factors for abuse, addiction, and misuse. Once dosage is determined, drug is given once daily. Dosage may be increased by 4 to 8 mg every 3 to 4 days, as needed.

***DOSAGE ADJUSTMENT*** For patients with hepatic or renal impairment, dosage started at 25% (moderate hepatic impairment) to 50% (moderate renal impairment) of normal dosage.

---

Route	Onset	Peak	Duration
P.O.	30 min	1.5–2 hr	4 hr

Route	Onset	Peak	Duration
I.V.	10-15 min	15-30 min	2-3 hr
I.M.	15 min	30-60 min	4-5 hr
SubQ	15 min	30-90 min	4 hr
P.R.	30 min	Unknown	4 hr

## Mechanism of Action

May bind with opioid receptors in the spinal cord and higher levels in the CNS. In this way, hydromorphone is believed to stimulate kappa and mu receptors, thus altering the perception of and emotional response to pain.

## Contraindications

Acute asthma (in an unmonitored setting or in the absence of resuscitative equipment); history of narrowing of the GI tract or presence of blind loops in the GI tract, or GI obstruction, including paralytic ileus; hypersensitivity to hydromorphone, hydromorphone salts, sulfite-containing drugs, or their components; opioid nontolerant patients (Dilaudid HP, Exalgo); paralytic ileus; severe respiratory depression

## Interactions

### DRUGS

*5-HT<sub>3</sub> receptor antagonists, drugs that affect the serotonin neurotransmitter system (mirtazapine, trazodone, tramadol), linezolid, methylene blue (I.V.), selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, tricyclic*

*antidepressants triptans, tryptophan:* Increased risk of serotonin syndrome

*anticholinergics:* Increased risk of ileus, severe constipation, or urine retention

*anxiolytics, antipsychotics, benzodiazepines and other CNS depressants, general anesthetics, muscle relaxants, other opioids and sedative/hypnotics, sedating antihistamines, tranquilizers, tricyclic antidepressants:* Increased risk of coma, hypotension, profound sedation, and severe respiratory depression

*diuretics:* Reduced effects of diuretics

*mixed agonist/antagonist, partial agonist opioid analgesics such as buprenorphine, butorphanol, nalbuphine,*

*pentazocine:* Possibly reduced analgesic effect of hydromorphone; may precipitate withdrawal symptoms

*MAO inhibitors:* Increased risk of serotonin toxicity; increased risk of opioid toxicity

*muscle relaxants:* Possibly enhanced neuromuscular blocking action of skeletal muscle relaxants producing increased degree of respiratory depression

## **ACTIVITIES**

*alcohol use:* Increased CNS and respiratory depression, which may become severe

## **Adverse Reactions**

**CNS:** Anxiety, **CNS depression**, confusion, dizziness, drowsiness, euphoria, hallucinations, headache, nervousness, restlessness, sedation, somnolence, tremor, weakness

**CV:** Hypertension, orthostatic hypotension, palpitations, tachycardia

**EENT:** Blurred vision, diplopia, dry mouth, **laryngeal edema**, **laryngeal spasms**, nystagmus, tinnitus

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal cramps, anorexia, biliary tract spasm, constipation, **hepatotoxicity**, nausea, vomiting

**GU:** Decreased libido, dysuria, erectile dysfunction, impotence, infertility, lack of menstruation, urine retention

**RESP:** Dyspnea, **respiratory depression**, wheezing

**SKIN:** Diaphoresis, flushing

**Other:** Injection-site pain, redness, and swelling; physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the newborn. Monitor newborn closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for excess drowsiness and respiratory depression.

## **REPRODUCTION**

- Chronic use of opioids may reduce fertility.

## **Nursing Considerations**

- Be aware that hydromorphone therapy increases risk of abuse, addiction, and misuse. A Risk Evaluation and Mitigation Strategy (REMS) is required. Monitor patient closely throughout therapy for abuse, addiction, or misuse.
- Know that chronic maternal use of hydromorphone during pregnancy can result in neonatal opioid withdrawal syndrome (NOWS), which may be life-threatening, if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to opioid drugs for a prolonged period while in utero.
- Use extreme caution when administering hydromorphone to patients with cor pulmonale or significant chronic obstructive pulmonary disease, and in patients having a substantially decreased respiratory reserve, hypercapnia, hypoxia, or preexisting respiratory depression, especially when initiating and titrating therapy. These patients may develop respiratory depression, even with usual therapeutic doses, because hydromorphone may decrease the patient's respiratory drive to the point of apnea.
- Use hydromorphone cautiously in, cachectic, debilitated, or elderly patients, especially when initiating and titrating therapy, as they are at increased risk for adverse effects, especially respiratory depression.
- Use hydromorphone cautiously in patients whose ability to maintain a normal blood pressure is already compromised by a reduced blood volume or concurrent administration of certain CNS depressant drugs; the drug may cause severe hypotension in these patients, especially when initiating or titrating the dose of hydromorphone.

- Be aware that hydromorphone should only be used concomitantly with benzodiazepines and other CNS depressants in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of hydromorphone to be limited. Monitor patient closely for signs and symptoms of decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately, expect drug to be discontinued, and provide emergency supportive care, as death may occur.
- Be aware that to improve analgesic action, give hydromorphone before pain becomes intense.
- Give I.V. form by direct injection over at least 2 minutes. For infusion, mix drug with D<sub>5</sub>W, normal saline solution, or Ringer's solution.
- Rotate I.M. and subcutaneous injection sites.

**WARNING** Monitor patient for respiratory depression, especially within the first 72 hours of initiating therapy or when increasing dosage, even when the drug has been used as prescribed and not abused or misused. Patients who are especially vulnerable include the elderly and those who are cachectic or debilitated. Be aware that overestimating hydromorphone dose when converting patients from another opioid medication can result in fatal overdose with the first dose. To avoid this, know that it is recommended to underestimate a patient's 24-hour oral hydromorphone requirement and provide rescue medication, as needed, until the right dose is determined. Keep resuscitation equipment and naloxone nearby.

- Be aware that drug can cause sleep-related breathing disorders including central sleep apnea and sleep-related hypoxemia that may require a dosage decrease, if present.
- Monitor patient for coma, hypotension, profound sedation, or respiratory depression when administering hydromorphone around-the-clock; these reactions can occur if alcohol or illicit drugs are being used without the prescriber's knowledge.

**WARNING** Know that many drugs may interact with opioids like hydromorphone to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect to do diagnostic testing. If diagnosis is confirmed, expect to administer corticosteroids and wean patient off hydromorphone, if possible.
- Monitor patients with seizure disorders because hydromorphone therapy may aggravate or induce convulsions.
- Monitor effectiveness of hydromorphone in relieving pain; consult prescriber as needed.
- Assess patient for constipation.
- Monitor patient for evidence of physical abuse or dependence. Be aware that excessive use of opioids such as hydromorphone may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely.
- Anticipate that drug may mask or worsen gallbladder pain.
- Be aware that all other around-the-clock opioid analgesics should be stopped when E.R. tablets are prescribed. Expect to give immediate-release nonopioid analgesics for exacerbation of pain and for preventing pain during certain activities.
- Know that E.R. tablets may be visible on abdominal X-rays under certain circumstances, especially when digital enhancing techniques are utilized, because the tablet is nondeformable and does not change much in shape in the GI tract.
- Expect to taper dosages of hydromorphone that have been administered for an extended period of time to the opioid-tolerant patient gradually by

25 to 50% every 2 to 3 days, down to a dose of 8 mg before the drug is discontinued. This will help prevent signs and symptoms of withdrawal.

## **PATIENT TEACHING**

- Instruct patient to take drug exactly as prescribed and before pain is severe. Also, tell her not to take more drug than prescribed and not to take it longer than absolutely needed, because excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death.
- Alert patient that drug is a controlled substance. She should take steps to protect drug from theft.
- Advise patient to take drug with food to avoid GI distress.
- Tell patient not to break, chew, crush, or dissolve E.R. tablets, but to swallow them whole.
- Instruct patient to refrigerate suppositories.
- Inform patient about potentially fatal additive effects of combining hydromorphone with a benzodiazepine. In addition, other serious drug reactions can occur. Instruct patient to inform all prescribers of hydromorphone use.
- Caution patient to avoid alcohol and OTC drugs during therapy, unless prescriber approves.
- Instruct patient to report constipation, difficulty breathing, severe nausea, or vomiting.
- Inform patient that drug may cause drowsiness and sedation. Advise her to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to change position slowly to minimize orthostatic hypotension.
- Instruct physically dependent patient not to stop taking hydromorphone abruptly to avoid withdrawal.
- Warn patient to keep drug out of reach of children, as accidental ingestion may cause death.
- Advise women of childbearing age to notify prescriber immediately if they suspect they are pregnant or become pregnant because hydromorphone may cause fetal harm or neonatal withdrawal that could be life-threatening.
- Advise patients when hydromorphone tablets or solution are no longer needed to remit to authorities at a certified drug take-back program.

- Inform patient that long-term use of opioids like hydromorphone may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any such symptoms.
- Advise patients to flush unused drug down the toilet or take to a proper disposal place when drug is no longer needed.

## hydroxychloroquine sulfate

### Plaquenil

## Class and Category

*Pharmacologic class:* Aminoquinoline

*Therapeutic class:* Antimalarial, antirheumatic, lupus erythematosus suppressant

## Indications and Dosages

➤ *To prevent malaria*

### **TABLETS**

**Adults.** 400 mg the same day of each week starting 2 wk before entering endemic area and continued for 4 wk after departure from endemic area.

**Children.** 6.5 mg/kg the same day of each week, starting 2 wk before entering endemic area and continued for 4 wk after departure from endemic area. *Maximum:* 400 mg once weekly.

➤ *To treat uncomplicated malaria caused by Plasmodium falciparum, P. malariae, P. ovale, or P. vivax*

## **TABLETS**

**Adults.** *Initial:* 800 mg, followed by 400 mg in 6 hr, 24 hr, and 48 hr after initial dose.

**Children.** *Initial:* 13 mg/kg (up to 800 mg), then 6.5 mg/kg (up to 400 mg) at 6 hr, 24 hr, and 48 hr after initial dose.

- *To treat chronic discoid and systemic lupus erythematosus*

## **TABLETS**

**Adults.** 200 to 400 mg daily as a single dose or in 2 divided doses. *Maximum:* 400 mg daily.

- *To treat acute or chronic rheumatoid arthritis*

## **TABLETS**

**Adults.** *Initial:* 400 to 600 mg daily as a single dose or in 2 divided doses. Following a good response, dosage reduced by 50%. *Maintenance:* 200 mg to 400 mg daily as a single dose or in 2 divided doses. *Maximum:* 600 mg daily or 6.5 mg/kg daily, whichever is lower.

***DOSAGE ADJUSTMENT*** For patients with hepatic or renal disease or for patients who are taking medications known to affect these organs, dosage may need to be reduced.

## **Mechanism of Action**

May mildly suppress the immune system, inhibiting production of rheumatoid factor and acute phase reactants.

Hydroxychloroquine also accumulates in WBCs, stabilizing lysosomal membranes and inhibiting enzymes such as collagenase and proteases that cause cartilage breakdown. These actions may decrease symptoms of rheumatoid arthritis and lupus erythematosus.

Hydroxychloroquine also binds to and alters DNA of malaria parasite to prevent it from reproducing. It also may increase the pH of acid vesicles, which interferes with vesicle function and may inhibit parasitic phospholipid metabolism in erythrocytes, thereby halting plasmodial activity.

## Contraindications

Hypersensitivity to hydroxychloroquine, other 4-aminoquinoline compounds, or their components

## Interactions

### DRUGS

*ampicillin*: Possibly significant decrease in bioavailability of ampicillin, decreasing its effectiveness

*antacids, kaolin*: Possible reduced absorption of hydroxychloroquine

*antidiabetic drugs, insulin*: Possible increased risk of hypoglycemia

*antiepileptics, mefloquine, other drugs that lower seizure threshold*: Increased risk of seizures

*cimetidine*: Possibly increased plasma hydroxychloroquine levels

*cyclosporin*: Increased plasma cyclosporin levels

*digoxin*: Increased digoxin concentrations

*drugs that prolong QT interval, including other*

*arrhythmogenic drugs*: Increased risk of arrhythmias

*hepatotoxic or nephrotoxic drugs*: Possibly increased risk of kidney or liver toxicity

*methotrexate*: Possible increased risk of adverse reactions

*praziquantel*: Possible reduced bioavailability of praziquantel affecting its effectiveness

# Adverse Reactions

**CNS:** Abnormal nerve conduction, ataxia, dizziness, emotional lability, fatigue, extrapyramidal disorders, headache, irritability, lassitude, nervousness, neuromuscular sensory abnormalities, nightmares, psychosis, **seizures**, **suicidal ideation**, vertigo

**CV:** **Atrioventricular blocks**, bundle branch block, **cardiomyopathy** (prolonged high doses), **prolonged QT interval**, **torsades de pointes**, **ventricular arrhythmias**

**EENT:** Abnormal pigmentation (bullseye appearance) or colored vision, blurred vision, central scotoma with decreased visual acuity, corneal deposits, decreased corneal sensitivity, diplopia, irreversible retinal damage, halo vision, lassitude, macular atrophy or edema, nerve-related hearing loss, nystagmus, paracentral or pericentral scotoma, photophobia, retinal fundus changes, tinnitus, visual abnormalities including visual fields

**ENDO:** **Hypoglycemia**

**GI:** Abdominal cramps, **acute or fulminant hepatic failure**, anorexia, diarrhea, elevated liver enzymes, nausea, vomiting

**HEME:** **Agranulocytosis**, anemia, **aplastic anemia**, **bone marrow failure**, **hemolysis** (in patients with glucose-6 phosphate dehydrogenase [G6PD] deficiency), **leukopenia**, **thrombocytopenia**

**MS:** Atrophy of proximal skeletal muscle groups, depressed tendon reflexes, muscle weakness, myopathy

**RESP:** **Bronchospasm**

**SKIN:** Acute generalized exanthematous pustulosis, alopecia, altered mucosal and skin pigmentation, bleaching

of hair, dermatitis (including bullous and **exfoliative dermatitis**), **erythema multiforme**, non-light-sensitive psoriasis, photosensitivity, pruritus, psoriasis exacerbation, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, porphyria including worsening, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug may cause fetal harm but it crosses the placental barrier and may cause central nervous system damage.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding. Infants are extremely sensitive to the toxic effects of this type of drug.

## Nursing Considerations

- Use hydroxychloroquine cautiously in patients with G6PD deficiency, patients with alcoholism or hepatic or renal disease, and patients taking hepatotoxic drugs. Also use cautiously in patients with blood, gastrointestinal, or neurological disorders and in patients who are sensitive to quinine.
- Monitor children closely for adverse reactions because they're especially sensitive to 4-aminoquinoline compounds.
- Observe patients with psoriasis closely because hydroxychloroquine may lead to severe psoriasis attack. Also monitor patients with porphyria

closely because hydroxychloroquine may worsen it. Expect to use hydroxychloroquine in patients with porphyria or psoriasis only after risks and benefits have been considered.

- Obtain periodic blood cell counts, as ordered, during prolonged therapy to detect adverse hematologic effects. Expect to stop drug if severe adverse effects occur.
- Monitor patient's vision when giving hydroxychloroquine, because irreversible retinal damage may occur in some patients during high-dose or long-term therapy. Ask regularly about vision abnormalities, such as light flashes or streaks that may indicate retinopathy. Expect patient to have an initial ophthalmologic examination, followed by examinations every 3 months. Be aware that in patients of Asian descent, retinal toxicity may first be noticed outside the macula. Report changes to prescriber immediately, and expect drug to be stopped. Retinal changes may progress even after therapy stops.
- Monitor patient on long-term therapy for muscle weakness and abnormal ankle and knee reflexes. If present, notify prescriber and expect drug to be stopped.
- Expect drug to be stopped if patient with rheumatoid arthritis shows no improvement, such as reduced joint swelling or increased mobility, in 6 months.
- Notify prescriber immediately if serious adverse reactions occur. Expect drug to be stopped. Also expect to give ammonium chloride (8 g daily in divided doses for adults) 3 or 4 days weekly for several months because acidification of urine increases renal excretion of drug.

## **PATIENT TEACHING**

- Instruct patient to take drug with meals or milk to minimize stomach upset.
- Tell patient to take hydroxychloroquine exactly as prescribed because taking too much may cause serious adverse reactions and taking too little or skipping doses decreases effectiveness.
- Caution patient to notify prescriber about troublesome adverse reactions. Hydroxychloroquine dosage may need to be adjusted or drug stopped.
- Caution patient about possible visual reactions and the need for periodic eye examinations. Tell patient to notify prescriber about abnormal visual changes, including blurred vision, halos around lights, and light flashes or streaks; explain that drug will need to be stopped.

- Tell patient receiving prolonged therapy about the need for periodic blood tests to detect adverse effects.
- Advise patient to notify prescriber if muscle weakness develops.
- Review early signs and symptoms of toxicity. Tell patient to notify prescriber immediately, if present.
- Inform mothers wishing to breastfeed that drug is excreted in breast milk and that infants are extremely sensitive to the toxic effects of drug. Advise them to discuss breastfeeding with prescriber before doing so.
- Warn patient to keep drug out of reach of children, as fatalities have occurred when drug has been accidentally ingested, even in small amounts.

## hydroxyzine hydrochloride

**Atarax (can)**

## hydroxyzine pamoate

**Vistaril**

### Class and Category

*Pharmacologic class:* Piperazine derivative

*Therapeutic class:* Anxiolytic, Antiemetic, antihistamine, sedative-hypnotic

### Indications and Dosages

- *To relieve anxiety and tension associated with psychoneurosis; adjunct in organic disease states in which anxiety is manifested*

## **CAPSULES, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults and adolescents.** 50 to 100 mg four times daily.

**Children age 6 and over.** 50 to 100 mg daily in 4 divided doses.

**Children under 6 years of age.** 50 mg daily in 4 divided doses.

### **I.M. INJECTION**

**Adults and adolescents.** 50 to 100 mg every 4 to 6 hr, as needed.

➤ *To treat pruritus due to allergic conditions*

## **CAPSULES, ORAL SUSPENSION, SYRUP, TABLETS**

**Adults and adolescents.** 25 mg three times daily or four times daily, as needed.

**Children age 6 and over.** 50 to 100 mg daily in 4 divided doses.

**Children under 6 years of age.** 50 mg daily in 4 divided doses.

➤ *As a sedative when used as premedication and following general anesthesia*

### **I.M. INJECTION**

**Adults and adolescents.** 50 to 100 mg.

**Children.** 0.6 mg/kg.

***DOSAGE ADJUSTMENT*** For elderly patients, treatment is started at lowest possible dosage.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	15-60 min	Unknown	4-6 hr
I.M.	20-30 min	Unknown	4-6 hr

## Mechanism of Action

Competes with histamine for histamine<sub>1</sub> receptor sites on surfaces of effector cells. This suppresses results of histaminic activity, including edema, flare, and pruritus. Sedative actions occur at subcortical level of CNS and are dose related.

## Contraindications

Early pregnancy; hypersensitivity to cetirizine, hydroxyzine, levocetirizine or their components; prolonged QT interval

## Interactions

### DRUGS

*antibiotics such as azithromycin, erythromycin, clarithromycin, gatifloxacin, or moxifloxacin;*  
*antidepressants such as citalopram or fluoxetine;*  
*antipsychotics such as chlorpromazine, clozapine, iloperidone, quetiapine, or ziprasidone; class IA*  
*antiarrhythmics such as procainamide or quinidine; class*  
*III antiarrhythmics such as amiodarone or sotalol;*  
*droperidol; methadone; ondansetron;*  
*pentamidine: Increased risk of QT prolongation*  
*CNS depressants: Increased CNS depression*

### ACTIVITIES

*alcohol use: Increased CNS depression*

## Adverse Reactions

**CNS:** Drowsiness, hallucinations, headache, involuntary motor activity, **seizures**, tremor

**CV:** **Prolonged QT interval**, **torsades de pointes**

**EENT:** Dry mouth

**SKIN:** Fixed drug eruptions, pruritus, rash, urticaria

**Other:** **Hypersensitivity reactions**, injection-site pain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in early pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

## Nursing Considerations

- Use hydroxyzine cautiously in patients with risk factors for QT prolongation such as concomitant arrhythmogenic drug use, electrolyte imbalance, or preexisting heart disease. Also use cautiously in patients with bradyarrhythmias, congenital or family history of long QT syndrome, other conditions that predispose patient to QT prolongation and ventricular arrhythmia, recent MI, or uncompensated heart failure.
- Don't give hydroxyzine by subcutaneous or I.V. route because tissue necrosis may occur.
- Inject I.M. form deep into large muscle, using Z-track method.
- Observe for oversedation if patient takes another CNS depressant.

## PATIENT TEACHING

- Urge patient to avoid alcohol.
- Caution patient about drowsiness; tell her to avoid hazardous activities until drug's CNS effects are known.
- Instruct woman to tell prescriber if she is or could be pregnant because drug is contraindicated in early pregnancy.

**ibalizumab-uiyk**

**Trogarzo**

## Class and Category

*Pharmacologic class:* CD4-directed post-attachment HIV-1 inhibitor

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV) type 1 infection in heavily treatment-experienced patients with multidrug-resistant HIV-1 infection who are failing their current antiretroviral regimen*

## I.V. INFUSION

**Adults.** *Loading:* 2,000 mg infused over at least 30 min.  
*Maintenance:* 800 mg infused 2 wk later and every 2 wk

thereafter. Infused over 15 min providing no infusion reaction occurred with loading dose.

## Mechanism of Action

Blocks HIV-1 from infecting CD4 T cells by binding to domain 2 of CD4 and interfering with post-attachment steps required for entry of HIV-1 virus particles into host cells. Also prevents the viral transmission that occurs via cell-cell infusion.

## Contraindications

Hypersensitivity to ibalizumab-uiyk or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Dizziness

**ENDO:** Hyperglycemia

**GI:** Diarrhea, elevated bilirubin and lipase levels, nausea

**GU:** Elevated creatinine level

**HEME:** Anemia, **decreased platelet count, leukopenia, neutropenia**

**SKIN:** Rash

**Other:** Antibody formation to ibalizumab-uiyk, elevated uric acid level, immune reconstitution inflammatory syndrome

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm although it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

# Nursing Considerations

- Use 10 vials to prepare the loading dose of 2,000 mg and 4 vials to prepare each maintenance dose of 800 mg. To prepare, insert sterile syringe needle into each vial through center of stopper, withdraw 1.33 ml of drug, and transfer into a 240-ml intravenous bag of 0.9% sodium chloride injection, USP. Do not use any other diluent solutions. Once diluted, administer immediately or store at room temperature for up to 4 hours or refrigerated for up to 24 hours. If refrigerated, allow diluted drug solution to stand at room temperature for at least 30 minutes but no more than 4 hours prior to administration.
- Administer infusion in the cephalic vein of patient's left or right arm. If this vein is not accessible, know that an appropriate vein located elsewhere can be used. Never administer drug as an IV bolus or IV push.
- Infuse loading dose over at least 30 minutes or more. If no infusion-associated adverse reactions occur, maintenance infusion time can be decreased to no less than 15 minutes. After infusion is complete, flush intravenous line with 30 ml of 0.9% sodium chloride injection, USP.

- Observe patient for 1 hour after loading-dose infusion is complete. If no infusion-associated adverse reactions occur, time of observation can be decreased to 15 minutes for subsequent maintenance infusions.
- Know that if a maintenance dose is missed by 3 days or longer beyond the scheduled dosing day, a loading dose of 2,000 mg should be administered as early as possible and the maintenance dosing of 800 mg resumed 2 weeks later.
- Monitor patient for signs and symptoms of infection, which could be caused by immune reconstitution inflammatory syndrome. Although rare, this syndrome may occur in combination with other antiretroviral therapy in patients whose immune systems respond during the initial phase causing an inflammatory reaction to indolent or residual opportunistic infections. If present, further evaluation and treatment will be needed.

## **PATIENT TEACHING**

- Stress importance of compliance with dosage schedule of every 2 weeks. Remind patient that if dose is missed for 3 days or longer, a loading dosage will have to be repeated before maintenance dosing can be reestablished.
- Instruct patient to immediately report any signs and symptoms of an infection to prescriber.
- Inform women of childbearing age to notify prescriber if pregnancy occurs, and encourage patient to enroll in the pregnancy exposure registry.
- Advise mothers not to breastfeed their infant while receiving ibalizumab-uiyk.

**ibandronate sodium**

**Boniva**

## **Class and Category**

*Pharmacologic class:* Bisphosphonate  
*Therapeutic class:* Antiosteoporotic

## Indications and Dosages

- *To prevent osteoporosis in postmenopausal women*

### **TABLETS**

**Adult women.** 150 mg once monthly taken same day of each month.

- *To treat osteoporosis in postmenopausal women*

### **TABLETS**

**Adult women.** 150 mg once monthly taken same day of each month.

### **I.V. INJECTION**

**Adults.** 3 mg injected over 15 to 30 sec every 3 mo.

## Mechanism of Action

Based on its affinity for hydroxyapatite, which is part of the mineral matrix of bone, osteoclast activity is inhibited and bone resorption and turnover is reduced. In postmenopausal women, the elevated rate of bone turnover is reduced leading to, on average, a net gain in bone mass.

## Incompatibilities

Do not mix with calcium-containing solutions or other intravenously administered drugs.

# Contraindications

Esophageal abnormalities that delay esophageal emptying, such as achalasia or stricture (oral form); hypersensitivity to ibandronate or its components; inability to stand or sit upright for at least 60 minutes (oral form); uncorrected hypocalcemia

# Interactions

## DRUGS

*aspirin, NSAIDs*: Increased risk of GI irritation  
*products containing calcium and other multivalent cations such as aluminum, magnesium, iron*: Impaired absorption of ibandronate

## FOODS

*all foods*: Decreased ibandronate bioavailability

# Adverse Reactions

**CNS**: Asthenia, depression, dizziness, fatigue, headache, insomnia, nerve root lesion, vertigo

**CV**: Hypercholesterolemia, hypertension

**EENT**: Nasopharyngitis, pharyngitis, tooth disorder

**GI**: Abdominal pain, constipation, diarrhea, dyspepsia, gastritis, gastroenteritis, nausea, vomiting

**GU**: Cystitis, UTI

**MS**: Arthralgia; arthritis; atypical subtrochanteric and diaphyseal femoral fractures; back, bone, extremity, joint,

or muscle pain; joint disorder; localized osteoarthritis; myalgia; osteonecrosis of jaw and other orofacial sites

**RESP:** **Asthma exacerbations**, bronchitis, **bronchospasm**, pneumonia, upper respiratory infection

**SKIN:** Dermatitis bullous, **erythema multiforme**, rash, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, **angioedema**, **hypersensitivity reactions**, infection, flu-like symptoms, **hypocalcemia**, injection-site reactions such as redness or swelling

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Drug is not indicated for use in women of reproductive potential.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug is not indicated for use in women of reproductive potential.

## Nursing Considerations

- Be aware that hypocalcemia, hypovitaminosis D, and other disturbances of bone and mineral metabolism must be effectively treated before starting ibandronate therapy.
- Know that ibandronate should not be administered to patients with severe renal impairment or to women who are not postmenopausal.
- Use cautiously in patients with active upper gastrointestinal problems (such as known Barrett's esophagus, dysphagia, other esophageal diseases, duodenitis, gastritis, ulcers because drug may cause local irritation of the upper gastrointestinal mucosa).

- Make sure patient has had a dental checkup before having invasive dental procedures during ibandronate therapy, especially if patient has cancer; is receiving chemotherapy, head or neck radiation, or a corticosteroid; or has poor oral hygiene, because the risk of jaw osteonecrosis has increased in these patients taking other bisphosphonates, a class of drugs of which ibandronate is a member.
- Obtain serum creatinine level in patients receiving injection form of ibandronate prior to administering each dose because other bisphosphonates have been associated with serious renal toxicity. If renal deterioration occurs, expect drug to be withheld.
- Administer parenteral ibandronate intravenously over 15 to 30 seconds using the needle provided. Prefilled syringes are for single use only. Be careful not to inject drug intra-arterially or paravenously, as this could lead to tissue damage.
- Administer drug as soon as possible after a missed appointment for parenteral ibandronate therapy. Schedule next injection from the date of the last injection, as drug must not be administered more frequently than once every 3 months.

## **PATIENT TEACHING**

- Instruct patient prescribed oral ibandronate to take the tablet at least 1 hour before first food or drink of day (except water) while in an upright position and with 6 to 8 oz of water. Caution against lying down for at least 60 minutes after taking drug to keep it from lodging in esophagus and causing irritation. Also instruct patient not to chew or suck on tablet because doing so may irritate mouth or throat.
- Inform patient of need and importance of taking supplemental calcium and vitamin D on daily basis.
- Instruct patient to take calcium supplements at least 2 hours before or after oral ibandronate.
- Advise patient to stop taking drug and to notify prescriber if GI symptoms appear or become worse.
- Alert patient that drugs in the same class as ibandronate have caused severe bone, joint, or muscle pain. If such symptoms appear while taking ibandronate, advise patient to contact prescriber. Also, tell him to report new or worsening groin or thigh pain.
- Tell patient to stop taking drug and notify prescriber if he develops dysphagia, pain while swallowing, retrosternal pain, or new or worsening heartburn.

- Inform women of childbearing age that drug is not used in their age group because of risk to fetal skeleton if pregnancy were to occur.
- Instruct patient on proper oral hygiene and on the need to notify prescriber about invasive dental procedures because risk of developing osteonecrosis of the jaw decreases in the absence of bisphosphonate therapy.

## ibuprofen

**Actiprofen Caplets (CAN), Advil, Advil Migraine, Apo-Ibuprofen (CAN), Caldolor, Children's Advil, Children's Motrin, Excedrin IB, Midol IB, Motrin, Motrin-IB, ibuprofen lysine, NeoProfen**

### Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic, anti-inflammatory, antipyretic

### Indications and Dosages

- *To relieve pain in rheumatoid arthritis and osteoarthritis*

**CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 300 mg four times daily; or 400, 600, or 800 mg three times daily; or four times daily. *Usual:* 1.2 to 3.2 g daily.

➤ *To relieve pain in juvenile arthritis*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Children ages 6 months and over.** 20 to 40 mg/kg daily in 3 or 4 divided doses.

*Maximum:* 40 mg/kg daily.

➤ *To relieve mild to moderate pain*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults.** 400 mg every 4 to 6 hr, as needed.

**Children age 12 and older.** 200 to 400 mg every 4 to 6 hr, as needed. *Maximum:* 1.2 g.

**Children age 11 weighing 33 kg (72 lb) to 43 kg (95 lb).** 300 mg every 6 to 8 hr, as needed.

**Children ages 9 and 10 weighing 27 kg (59 lb) to 32 kg (70 lb).** 250 mg every 6 to 8 hr, as needed.

**Children ages 6 to 8 weighing 22 kg (48 lb) to 27 kg (59 lb).** 200 mg every 6 to 8 hr, as needed.

**Children ages 4 and 5 weighing 16 kg (35 lb) to 21 kg (46 lb).** 150 mg every 6 to 8 hrs, as needed.

**Children ages 2 and 3 weighing 11 kg (24 lb) to 16 kg (35 lb).** 100 mg every 6 to 8 hrs, as needed.

## **I.V. INFUSION (COLDOLOR)**

**Adults.** 400 to 800 mg infused over at least 30 min, every 6 hr, as needed. *Maximum:* 3,200 mg daily.

**Adolescents.** 400 mg infused over at least 10 min, every 4 to 6 hr, as needed. *Maximum:* 2,400 mg daily.

**Children ages 6 months to 12 years.** 10 mg/kg up to 400 mg maximum for single dose infused over at least 10 min, every 4 to 6 hr, as needed. *Maximum:* 40 mg/kg or 2,400 mg daily, whichever is less.

➤ *To relieve moderate to severe pain as an adjunct to opioid analgesics*

## **I.V. INFUSION (CALDOLOR)**

**Adults.** 400 to 800 mg infused over at least 30 min, every 6 hr, as needed.

➤ *To reduce fever*

## **CAPSULES, CHEWABLE TABLETS, ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** 200 to 400 mg every 4 to 6 hr, as needed.

**Children age 11 weighing 33 kg (72 lb) to 43 kg (95 lb).** 300 mg every 6 to 8 hr, as needed.

**Children ages 9 and 10 weighing 27 kg (59 lb) to 32 kg (70 lb).** 250 mg every 6 to 8 hr, as needed.

**Children ages 6 to 8 weighing 22 kg (48 lb) to 27 kg (59 lb).** 200 mg every 6 to 8 hr, as needed.

**Children ages 4 and 5 weighing 16 kg (35 lb) to 21 kg (46 lb).** 150 mg every 6 to 8 hr, as needed.

**Children ages 2 and 3 weighing 11 kg (24 lb) to 16 kg (35 lb).** 100 mg every 6 to 8 hr, as needed.

## **I.V. INFUSION (CALDOLOR)**

**Adults.** 400 mg infused over at least 30 min, followed by 400 mg infused over at least 30 min, every 4 to 6 hr. Or,

100 to 200 mg infused over at least 30 min, every 4 hr, as needed. *Maximum:* 3,200 mg daily.

**Adolescents.** 400 mg infused over at least 10 min, every 4 to 6 hr, as needed. *Maximum:* 2,400 mg daily.

**Children ages 6 months to 12 years.** 10 mg/kg up to 400 mg maximum for single dose infused over at least 10 min, every 4 to 6 hr, as needed. *Maximum:* 40 mg/kg or 2,400 mg daily, whichever is less.

➤ *To treat patent ductus arteriosus*

## I.V. INFUSION (NEOPROFEN)

**Gestational age 32 weeks or less and weighing between 500 and 1,500 g**

*Initial:* 10 mg/kg (based on birth weight) infused over at least 15 min, followed by 5 mg/kg 24 hr later and 5 mg/kg 24 hr after second dose.

➤ *To relieve migraine pain and related symptoms, like nausea and sensitivity to light and sound.*

## CAPSULES (ADVIL MIGRAINE)

**Adults.** 400 mg as a single dose. *Maximum:* 400 mg/24 hr.

Route	Onset	Peak	Duration
P.O.*	30 min	Unknown	4–6 hr
P.O.†	Up to 7 days	1–2 wk	Unknown
P.O.†	In 1 hr	2–4 hr	6–8 hr
I.V.	10–30 min	Unknown	Unknown

\* For analgesic effects.

† For anti-inflammatory effects.

‡ For antipyretic effects.

## Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate inflammatory response and cause local pain, swelling, and vasodilation. By inhibiting prostaglandins, this NSAID reduces inflammatory symptoms and relieves pain. Ibuprofen's antipyretic action probably stems from its effect on the hypothalamus, which increases peripheral blood flow, causing vasodilation and encouraging heat dissipation.

## Contraindications

*For all forms except ibuprofen lysine:* Angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria caused by hypersensitivity to aspirin or other NSAIDs; hypersensitivity to ibuprofen or its components; pain with coronary artery bypass graft (CABG) surgery; *For ibuprofen lysine:* bleeding (especially active intracranial hemorrhage or gastrointestinal bleeding), coagulation defects, congenital heart disease in whom patency of the patent ductus arteriosus is necessary for satisfactory pulmonary or systemic blood flow (pulmonary atresia, severe coarctation of the aorta, severe tetralogy of Fallot), hypersensitivity to ibuprofen or its components, known or suspected infection or necrotizing enterocolitis, significant renal impairment, thrombocytopenia

## Interactions

### DRUGS

*angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), beta-blockers (including propranolol):* Possibly diminished antihypertensive effect of these drugs

*aspirin*: Possibly decreased cardioprotective and stroke-preventive effects of aspirin; increased risk of bleeding and adverse GI effects

*cyclosporine*: Increased risk of nephrotoxicity

*digoxin*: Increased blood digoxin level and risk of digitalis toxicity

*diuretics (loop, potassium-sparing, and thiazide)*:

Decreased diuretic and antihypertensive effects

*heparin, oral anticoagulants, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors,*

*thrombolytics*: Increased anticoagulant effects, increased risk of hemorrhage

*lithium*: Increased blood lithium level

*methotrexate*: Decreased methotrexate clearance and increased risk of toxicity

*other NSAIDs, salicylates*: Increased risk of GI toxicity

*pemetrexed*: Increased risk of GI and renal toxicity; myelosuppression

## ACTIVITIES

*alcohol use*: Increased risk of adverse GI effects

## Adverse Reactions

**CNS**: Aseptic meningitis, CVA, dizziness, headache, nervousness, seizures

**CV**: Fluid retention, heart failure, hypertension, MI, peripheral edema, tachycardia

**EENT**: Amblyopia, epistaxis, stomatitis, tinnitus

**GI**: Abdominal cramps, distention, or pain; anorexia; constipation; diarrhea; diverticulitis; dyspepsia; dysphagia; elevated liver enzymes; epigastric discomfort; esophagitis; flatulence; gastritis; gastroenteritis; gastroesophageal

reflux disease; **GI bleeding, hemorrhage, perforation**, or ulceration; heartburn; hemorrhoids; **hepatic failure; hepatitis**; hiatal hernia; indigestion; **melena**; nausea; stomatitis; vomiting

**GU:** Cystitis, hematuria, **renal failure (acute)**

**HEME:** **Agranulocytosis**, anemia, **aplastic anemia**, eosinophilia, **hemolytic anemia, leukopenia, neutropenia, pancytopenia, prolonged bleeding time, thrombocytopenia**

**RESP:** **Bronchospasm**, dyspnea, wheezing

**SKIN:** Blisters, **erythema multiforme**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis, angioedema**, flu-like symptoms, **hypokalemia**, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

### REPRODUCTION

- Drug may delay or prevent rupture of ovarian follicles, which may cause reversible infertility in some women.

## Nursing Considerations

- Be aware that ibuprofen should not be used in pregnant women starting at 30 weeks gestation because premature closure of the ductus arteriosus may occur in the fetus.
- Be aware that NSAIDs like ibuprofen should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Know that the risk of heart failure increases with use of NSAIDs such as ibuprofen. Ibuprofen should not be used in patients with severe heart failure but, if unavoidable, monitor patient for worsening of heart failure.
- Use ibuprofen with extreme caution in patients with a history of GI bleeding or ulcer disease because NSAIDs, such as ibuprofen, increase risk of GI bleeding and ulceration. Expect to use ibuprofen for shortest time possible in these patients.

**WARNING** Be aware that the risk of serious cardiovascular thrombotic events such as a MI or stroke increases the longer ibuprofen is used. Expect to give drug for shortest time possible. These events may occur early in treatment and happen even in patients who do not have a history or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, slurring of speech, shortness of breath, or weakness. If any signs and symptoms develop, withhold ibuprofen, alert prescriber immediately, and provide supportive care as prescribed.

- For I.V. use, dilute Caldolor brand of ibuprofen to final concentration of 4 mg/ml or less using 0.9% sodium chloride injection, 5% dextrose injection, or lactated Ringer's solution. For an 800-mg dose, dilute 8 ml Caldolor in at least 200 ml diluent; for a 400-mg dose, dilute 4 ml Caldolor in at least 100 ml diluent. Diluted solutions may be kept at room temperature up to

24 hours. When infusing ibuprofen intravenously, infusion time must be at least 30 minutes for adults and 10 minutes for children.

- Keep in mind that serious GI tract bleeding, perforation, and ulceration may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give oral drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use ibuprofen cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if he’s elderly or receiving long-term oral ibuprofen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes, as ordered, because, in rare cases, elevations may progress to severe hepatic reactions, including fatal hepatitis, hepatic failure, or liver necrosis.
- Monitor BUN and serum creatinine levels in elderly patients, patients taking ACE inhibitors or diuretics, and patients with heart failure, hepatic dysfunction or impaired renal function; drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit. Drug may worsen anemia.

**WARNING** Be aware that if patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection. Ibuprofen’s anti-inflammatory and antipyretic actions may mask signs and symptoms, such as fever and pain.

- Assess patient’s skin regularly for signs of rash or other hypersensitivity reaction because ibuprofen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.

- Expect higher doses for rheumatoid arthritis than for osteoarthritis.
- Be aware that ibuprofen oral suspension may contain sucrose, which may affect blood glucose level in diabetic patients.

## **PATIENT TEACHING**

- Instruct patient to take tablets with a full glass of water, and caution him not to lie down for 15 to 30 minutes to prevent esophageal irritation.
- Advise patient to take drug with food or after meals to reduce GI distress.
- Urge patient not to take higher doses of drug or for a longer time than prescribed because stomach bleeding may occur and risk of MI or stroke may increase.
- Instruct patient to consult prescriber if he needs to take drug for more than 3 days for fever or 10 days for pain; if stomach problems (heartburn, pain, or upset) recur; if he has a history of bleeding problems, heart or renal disease, hypertension, or ulcers; if he takes a diuretic; or if he's over age 65.
- Inform patient with phenylketonuria that Motrin chewable tablets contain aspartame.
- Inform patient that full therapeutic effect for arthritis may take 2 weeks or longer.
- Urge patient to avoid taking two different NSAIDs at the same time, unless directed, and to alert prescriber before taking ibuprofen if he has ever had an allergic reaction to any other analgesic or fever-reducing drug or has a history of asthma.
- Urge patient to avoid alcohol, aspirin, and corticosteroids while taking ibuprofen, unless prescribed. If patient takes aspirin as prevention of MI or stroke, explain that ibuprofen may interfere with this effect.
- Suggest that patient wear sunscreen and protective clothing when outdoors.
- Advise patient to report flu-like symptoms, rash, signs of GI bleeding, swelling, vision changes, and weight gain.
- Urge parents to tell prescriber promptly if child receiving drug develops headache, high fever, nausea, persistent diarrhea, severe persistent sore throat, or vomiting or hasn't been drinking fluids.
- Advise parents to consult prescriber before giving OTC ibuprofen to a child if the child has asthma, bleeding problems, heart or kidney disease,

high blood pressure, or ulcers; a need for diuretic therapy; serious adverse effects from previous use of fever reducers or pain relievers; or persistent stomach problems, such as heartburn, stomach pain or upset stomach.

- Caution pregnant patient not to take NSAIDs such as ibuprofen during last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that ibuprofen may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, edema, shortness of breath, slurring of speech, swelling in legs, unexplained weight gain, or weakness.
- Explain that ibuprofen may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention for such signs and symptoms as abdominal or epigastric pain, black or tarry stools, indigestion, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.

## ibutilide fumarate

### Corvert

## Class and Category

*Pharmacologic class:* Methanesulfonanilide derivative

*Therapeutic class:* Class III antiarrhythmic

## Indications and Dosages

- *To rapidly convert recent-onset atrial flutter or fibrillation to sinus rhythm*

### I.V. INFUSION

**Adults weighing 60 kg (132 lb) or more.** 1 mg infused over 10 min. Dose repeated 10 min after first dose is finished if arrhythmia persists.

**Adults weighing less than 60 kg (132 lb).** 0.01 mg/kg infused over 10 min. Dose is repeated 10 min after first dose is completed if arrhythmia persists.

***DOSAGE ADJUSTMENT*** Infusion stopped if arrhythmia is terminated or if nonsustained or sustained ventricular tachycardia or prolonged QT or QTc interval develops.

## Mechanism of Action

May promote sodium movement through slow inward sodium channels in myocardial cell membranes. Ibutilide also may inhibit potassium channels in myocardial cell membranes involved in cardiac repolarization. These actions prolong cardiac action potential by delaying repolarization and increasing atrial and ventricular refractoriness. As a result, sinus rate slows and AV conduction is delayed.

## Contraindications

Hypersensitivity to ibutilide or components

## Interactions

### DRUGS

*antihistamine drugs (selective) such as H1 receptor antagonists, class Ia antiarrhythmics (disopyramide, procainamide, quinidine), class III antiarrhythmics (amiodarone, sotalol), phenothiazines, tetracyclic or tricyclic antidepressants:* Possibly increased risk of

prolonged QT interval, leading to increased risk of proarrhythmias

*digoxin*: Possibly masking cardiotoxicity associated with excessive digoxin levels

## Adverse Reactions

**CNS:** Headache, syncope

**CV:** **AV block**, **bradycardia**, bundle-branch block, **heart failure**, hypertension, **hypotension**, **idioventricular rhythm**, orthostatic hypotension, palpitations, **prolonged QT interval**, sinus tachycardia, **supraventricular arrhythmias**, **ventricular arrhythmias**

**GI:** Nausea

**GU:** **Renal failure**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm according to animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken while receiving drug.

## Nursing Considerations

- Know that before giving ibutilide, check serum electrolyte levels and expect to correct abnormalities, as prescribed. Be especially alert for hypokalemia and hypomagnesemia, which can lead to arrhythmias.
- Give drug undiluted or dilute in 50 ml normal saline solution or D<sub>5</sub>W. Add contents of 10-ml vial (0.1 mg/ml) to 50 ml solution to obtain 0.017 mg/ml. Use polyvinyl chloride plastic bags or polyolefin bags for admixtures. Give drug within 24 hours (48 hours if refrigerated).
- Infuse drug slowly over 10 minutes.
- As ordered, monitor patient's cardiac rhythm continuously during infusion and for at least 4 hours afterward—longer if arrhythmias appear or if patient has abnormal hepatic function. Observe patient for ventricular ectopy.
- Make sure defibrillator and drugs to treat sustained ventricular tachycardia are available during therapy and when monitoring patient after therapy.

## PATIENT TEACHING

- Inform patient that ibutilide will be given by I.V. infusion and that his heart rhythm will be monitored continuously.
- Ask patient to report chest pain, faintness, numbness, palpitations, shortness of breath, and tingling.
- Advise patient to keep follow-up appointments to monitor heart rhythm.

**icosapent ethyl**

**Vascepa**

## Class and Category

*Pharmacologic class:* Lipid-regulating agent

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *Adjunct to diet to reduce triglyceride levels in patients with severe (equal to or greater than 500 mg/dl) hypertriglyceridemia; adjunct to maximally tolerated statin therapy to reduce the risk of coronary revascularization, myocardial infarction, stroke, and unstable angina requiring hospitalization in patients with elevated triglyceride levels of 150 mg/dl or greater and diabetes mellitus and two or more additional risk factors for cardiovascular disease or established cardiovascular disease*

### **CAPSULES**

**Adults.** 2 g twice daily with food.

## Mechanism of Action

Reduces very low-density lipoprotein triglycerides (VLDL-TG) synthesis and/or secretion in the liver and enhances triglyceride clearance from circulating VLDL particles.

Mechanisms used to accomplish this may include decreased lipogenesis in the liver, increased beta oxidation, increased lipoprotein lipase activity, and inhibition of acyl-CoA:1,2-diacylglycerol acyltransferase. These mechanisms work together to lower triglyceride levels.

## Contraindications

Hypersensitivity to icosapent ethyl or its components

## Interactions

### **DRUGS**

*anticoagulants, antiplatelet drugs:* Possibly increased bleeding time

## Adverse Reactions

**CV:** **Atrial fibrillation** or **flutter**, elevated blood triglycerides, peripheral edema

**EENT:** Oropharyngeal pain

**GI:** Abdominal discomfort, constipation, diarrhea

**HEME:** **Increased risk of bleeding**

**MS:** Arthralgia, extremity or musculoskeletal pain

**Other:** Gout

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use icosapent ethyl cautiously in patients with a known hypersensitivity to fish and/or shellfish because the drug contains ethyl esters of the omega-3 fatty acid obtained from the oil of fish.

- Be aware that patient should have been placed on a lipid-lowering diet and exercise regimen before starting icosapent ethyl therapy.
- Know that efforts should be made to control conditions that may increase lipid abnormalities, such as alcohol intake, diabetes mellitus, and hypothyroidism.
- Expect medications known to exacerbate hypertriglyceridemia, such as beta blockers, estrogen therapy, and immunosuppressants to be changed or discontinued prior to icosapent ethyl therapy.
- Obtain lipid levels prior to initiating icosapent ethyl therapy, as ordered, to determine a baseline. Monitor lipid levels periodically throughout icosapent ethyl therapy to determine effectiveness.
- Monitor alanine aminotransferase and aspartate aminotransferase levels periodically, as ordered, in patients with hepatic impairment.
- Monitor patient for an irregular or fast heart rate because icosapent ethyl therapy increases the risk of atrial fibrillation or flutter that may be severe enough to require hospitalization. Incidence is greater in patients with a previous history of these arrhythmias.
- Institute bleeding precautions because icosapent ethyl increases risk of bleeding, especially if patient is taking antithrombotic drugs, such as aspirin, clopidogrel, or warfarin.

## **PATIENT TEACHING**

- Tell patient that icosapent ethyl therapy is not a substitution for diet and exercise but that these lifestyle changes need to continue during icosapent ethyl therapy.
- Instruct patient to take capsules whole and not to break, chew, crush, or dissolve open the capsules.
- Advise patient with known hypersensitivity to fish and/or shellfish about the potential for allergic reactions to icosapent ethyl. Tell patient to discontinue drug and seek medical attention if any reactions occur.
- Inform patient that periodic blood tests will be needed to monitor effectiveness of icosapent ethyl therapy.
- Teach patient how to take a pulse and to report an irregular or fast pulse immediately to prescriber.
- Review bleeding precautions with patient.

# idarucizumab

## Praxbind

### Class and Category

*Pharmacologic class:* Humanized monoclonal antibody fragment

*Therapeutic class:* Antidote

### Indications and Dosages

➤ *To reverse anticoagulant effects of dabigatran*

#### I.V. INFUSION, I.V. INJECTION

**Adults.** 5 g given in 2.5 g doses consecutively, and repeated one time, as needed. I.V. infused over 5 to 10 minutes with second 2.5 g dose given within 15 minutes of first 2.5 g dose. I.V. injection given as a bolus with second 2.5 g dose given consecutively after the first 2.5 g dose.

### Mechanism of Action

Binds to dabigatran and its acyl-glucuronide metabolites with higher affinity than the binding of dabigatran to thrombin, thereby neutralizing their anticoagulant effect and reversing the effects of dabigatran.

### Contraindications

Hypersensitivity to idarucizumab or its components

# Interactions

## DRUGS

None reported

# Adverse Reactions

**CNS:** Delirium, fever

**CV:** **Thrombotic events**

**GI:** Constipation

**RESP:** **Bronchospasm**, hyperventilation, pneumonia

**SKIN:** Pruritus, rash

**Other:** **Anaphylaxis**, formation of idarucizumab antibodies, **hypokalemia**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use extreme caution when administering idarucizumab to a patient with hereditary fructose intolerance because idarucizumab contains 4 g of sorbitol. The amount of sorbitol that may cause serious or even fatal adverse reactions is not known.
- Administer idarucizumab solution within 1 hour after it is removed from the vial. Expect to use two 2.5 g/50 ml vials and administer drug as 2.5 g doses back to back either as an intravenous infusion or injection. Flush intravenous line with 0.9% sodium chloride solution prior to administering drug. Do not coadminister any other drug in the same intravenous line.
- Provide standard supportive measures to control dabigatran induced bleeding, as needed, in conjunction with idarucizumab treatment.
- Monitor the patient's coagulation parameters such as activated partial thromboplastin time (aPTT) or ecarin clotting time (ECT), as ordered.
- Be prepared to administer an additional 5 g of idarucizumab, as ordered, if patient redevelops significant bleeding together with elevated coagulation parameters or if patient requires a second emergency surgery or urgent procedure and has elevated coagulation parameters.

**WARNING** Monitor patient closely for thrombotic events because reversing dabigatran with idarucizumab increases the risk of such events. Know that resumption of anticoagulant therapy should be done as soon as possible. For example, dabigatran may be resumed 24 hours after the administration of idarucizumab.

- Monitor patient for an allergic reaction to idarucizumab. If present, stop administration immediately, notify prescriber, and provide emergency supportive care, as indicated.

## **PATIENT TEACHING**

- Instruct patient to alert medical personnel immediately if she experiences difficulty breathing or develops skin reactions such as itchiness or a rash during or after idarucizumab has been administered.
- Alert patient that she will continue to need anticoagulant therapy once the bleeding episode has been resolved to prevent future blood clots. She may be able to resume dabigatran therapy 24 hours after idarucizumab therapy is given, if ordered.

- Tell her she will need blood tests to monitor effectiveness of idarucizumab therapy and that a second dose of idarucizumab may be required if bleeding reoccurs or an emergency procedure or surgery is required.

# iloperidone

## Fanapt

### Class and Category

*Pharmacologic class:* Atypical antipsychotic

*Therapeutic class:* Second-generation antipsychotic

### Indications and Dosages

➤ *To treat schizophrenia*

#### **TABLETS**

**Adults.** *Initial:* 1 mg twice daily, adjusted to target dosage range as follows: 2 mg twice daily on day 2, 4 mg twice daily on day 3, and 6 mg twice daily on day 4. Dosage may be further increased, as needed, as follows: 8 mg twice daily on day 5, 10 mg twice daily on day 6, and 12 mg twice daily on day 7. *Maximum:* 12 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients taking strong CYP2D6 inhibitors, such as fluoxetine and paroxetine, CYP3A4 inhibitors, such as clarithromycin and ketoconazole, or are poor metabolizers of CYP2D6, dosage reduced by half.

Route	Onset	Peak	Duration
P.O.	1-2 wk	2-4 hr	Unknown

## Mechanism of Action

Selectively blocks dopamine type 2 (D<sub>2</sub>) and serotonin type 2 (5-HT<sub>2</sub>) receptors in CNS, thereby suppressing psychotic symptoms.

## Contraindications

Hypersensitivity to iloperidone or its components

## Interactions

### DRUGS

*antibiotics such as fluoroquinolones or macrolides, class IA antiarrhythmics such as procainamide or quinidine, class III antiarrhythmics such as amiodarone or sotalol, other antipsychotic drugs such as chlorpromazine or thioridazine, or any other drug that affects the QT interval, such as methadone or pentamidine:* Possibly prolonged QT interval

*antihypertensive drugs:* Increased antihypertensive effects

*CNS depressants:* Possibly additive CNS effects

*CYP2D6 inhibitors such as fluoxetine or paroxetine,*

*CYP3A4 inhibitors such as ketoconazole:* Increased plasma iloperidone level

*dextromethorphan:* Increased blood dextromethorphan level

## Activities

*alcohol:* Possibly increased CNS effects

## Adverse Reactions

**CNS:** Aggression, delusion, dizziness, extrapyramidal effects, fatigue, lethargy, **neuroleptic malignant syndrome**, restlessness, **seizures**, somnolence, **suicidal ideation**, tremor

**CV:** **Congestive heart failure**, dyslipidemia, orthostatic hypotension, palpitations, **QT-interval prolongation**, tachycardia

**EENT:** Blurred vision, conjunctivitis, dry mouth, nasal congestion, nasopharyngitis, **oropharyngeal swelling**, **throat tightness**, upper respiratory tract infection

**ENDO:** **Diabetic ketoacidosis**, elevated prolactin levels, hyperglycemia, **hyperosmolar coma**

**GI:** Abdominal discomfort, diarrhea, nausea

**GU:** Ejaculation failure, erectile dysfunction, priapism, urinary incontinence

**HEME:** **Leukopenia**

**MS:** Arthralgia, musculoskeletal stiffness, spasms, myalgia

**RESP:** Dyspnea

**SKIN:** Pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- Drug may cause fetal harm.
- Exposure during third trimester increases risk of fetus developing extrapyramidal and/or withdrawal symptoms following delivery.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Know that iloperidone shouldn't be used in patients with a history of cardiovascular disease such as cardiac arrhythmias, QT-interval prolongation, recent MI, or uncompensated heart failure. It also shouldn't be used in patients taking other drugs known to prolong the QT interval and in patients with hepatic impairment.

**WARNING** Be aware that iloperidone shouldn't be used to treat patients with dementia-related psychosis, especially elderly patients, because of an increased risk of death.

- Use cautiously in patients who have a history of seizures or who have conditions that lower the seizure threshold, such as Alzheimer's dementia. Also use cautiously in patients who are at risk for aspiration pneumonia or who have moderate hepatic impairment (not recommended for use in patients with severe hepatic impairment).
- Expect to restart dosage adjustment schedule in patients who have been off iloperidone therapy for more than 3 days.
- Obtain baseline serum magnesium and potassium levels in patients at risk for electrolyte imbalances, and then monitor periodically throughout therapy, as ordered, because electrolyte imbalances increase risk of prolonged QT interval or arrhythmia. If patient reports dizziness, palpitations, or syncope, notify prescriber and expect further evaluation to be done.

**WARNING** Know that neuroleptic malignant syndrome has occurred in patients taking other antipsychotic drugs. Monitor patient for altered mental status, autonomic instability, hyperpyrexia, and muscle rigidity. If present, notify prescriber immediately, expect drug to

be discontinued, and start intensive treatment, as prescribed. Watch for recurrence if patient resumes antipsychotic therapy.

- Monitor patient for tardive dyskinesia, which has occurred with other antipsychotic drugs. If patient develops involuntary, dyskinetic movements, notify prescriber and expect to discontinue drug.
- Monitor blood glucose level, especially in patients with diabetes mellitus, because iloperidone may alter blood glucose enough to induce life-threatening hyperosmolar coma or ketoacidosis.
- Monitor patient's CBC periodically, as ordered, especially during first few months of therapy, because iloperidone may cause neutropenia. Also, be aware that other antipsychotic drugs have caused sometimes fatal agranulocytosis and leukopenia. If patient's WBC count decreases, expect drug to be discontinued.
- Monitor patient closely for abnormal tendencies that may suggest suicidal thinking, especially when iloperidone therapy starts or dosage is changed.

## **PATIENT TEACHING**

- Inform patient that when iloperidone therapy starts, dosage must be adjusted for up to a week to reach target level. Also explain that adjustment process will need to be repeated if she skips drug for more than 3 days.
- Advise patient or caregiver to notify prescriber about persistent severe, or unusual adverse reactions because drug may need to be discontinued.
- Urge patient or caregiver to report evidence of abnormal thinking, especially when therapy starts or dosage changes.
- Tell diabetic patient to monitor blood glucose levels closely and to report persistent elevations immediately to prescriber.
- Caution patient to avoid hazardous activities until CNS effects of drug are known. Patient should also avoid alcohol.
- Instruct patient to avoid activities that might raise body temperature, such as being exposed to extreme heat, being subjected to dehydration, doing strenuous exercise or taking other drugs with anticholinergic activity.
- Emphasize the need to comply with follow-up appointments and laboratory tests.

- Tell patient to rise slowly from lying to sitting position and from sitting position to standing to avoid dizziness or light-headedness during therapy.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy.

**imipramine hydrochloride**

**Tofranil**

**imipramine pamoate**

**Tofranil-PM**

## **Class and Category**

*Pharmacologic class:* Tricyclic antidepressant (TCA)

*Therapeutic class:* Antidepressant

## **Indications and Dosages**

➤ *To treat depression*

### **CAPSULES, TABLETS**

**Adults.** *Initial:* 75 mg (outpatient) or 100 to 150 mg (hospitalized) daily at bedtime or in divided doses, gradually increased as needed and tolerated. Dosage increased after 2 wk for dosages above 200 mg/day. *Maximum:* 300 mg daily (hospitalized patients), 200 mg/day (outpatients).

**Adolescents and elderly.** *Initial for capsules:* 25 to 50 mg daily at bedtime or in divided doses, adjusted as needed and tolerated. *Initial for tablets:* 30 to 40 mg daily at bedtime or in divided doses, adjusted as needed and tolerated. *Maximum:* 100 mg daily.

## I.M. INJECTION

**Adults unable or unwilling to use oral forms.** *Initial:* Up to 100 mg/day in divided doses, adjusted as needed and tolerated.

**Adolescents and elderly.** *Initial:* Lower than 100 mg/day, adjusted as needed and tolerated.

➤ *As adjunct to treat childhood enuresis*

## TABLETS

**Children age 6 and over.** *Initial:* 25 mg 1 hr before bedtime. Increased to 50 mg if no response occurs within 1 wk and child is under age 12; increased to 75 mg if child is age 12 or over. *Maximum:* 2.5 mg/kg daily.

***DOSAGE ADJUSTMENT*** For early night bedwetters, drug given earlier and in divided amounts such as 25 mg in afternoon and repeated at bedtime.

Route	Onset	Peak	Duration
P.O.	2-3 wk*	Unknown	Unknown

\* For antidepressant effect.

## Mechanism of Action

May interfere with reuptake of serotonin (and possibly other neurotransmitters) at presynaptic neurons, thus enhancing serotonin's effects at postsynaptic receptors. Mood elevation may result from restoration of normal

levels of neurotransmitters at nerve synapses. This tricyclic antidepressant also blocks acetylcholine receptors, which may explain how it relieves enuresis.

## Contraindications

Acute recovery period after MI; hypersensitivity to imipramine, other tricyclic antidepressants, or their components; use within 14 days of MAO inhibitor therapy, including intravenous methylene blue and linezolid

## Interactions

### DRUGS

*anticholinergics, antiparkinsonism drugs:* Risk of increased anticholinergic effects, including confusion, hallucinations, and nightmares

*barbiturates, phenytoin:* Possibly decreased imipramine level and effects

*CNS depressants:* Increased CNS depression, hypotension, and respiratory depression

*P450 2D6 inhibitors such as cimetidine, class IC*

*antiarrhythmics (flecainide, propafenone), other*

*antidepressants, phenothiazines, quinidine, selective*

*serotonin reuptake inhibitors (fluoxetine, paroxetine,*

*sertraline):* Increased concentrations of both drugs

*MAO inhibitors:* Increased risk of hypertensive crisis, severe seizures, and death

*oral anticoagulants:* Possibly increased anticoagulant activity

*sympathomimetics containing epinephrine or*

*norepinephrine such as decongestants, local anesthetics:*

Potentiated effects of catecholamines

## ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Anxiety, ataxia, chills, confusion, **CVA**, delirium, dizziness, drowsiness, excitation, extrapyramidal reactions, fever, hallucinations, headache, insomnia, nervousness, nightmares, Parkinsonism, **seizures**, **serotonin syndrome**, **suicidal ideation**, tremor

**CV:** **Arrhythmias**, orthostatic hypotension, palpitations

**EENT:** Blurred vision, dry mouth, increased intraocular pressure, pharyngitis, taste perversion, tinnitus, tongue swelling

**ENDO:** Gynecomastia, syndrome of inappropriate ADH secretion

**GI:** Constipation, diarrhea, heartburn, ileus, increased appetite, jaundice, nausea, vomiting

**GU:** Impotence, libido changes, testicular swelling, urine retention

**HEME:** **Agranulocytosis**, **bone marrow depression**

**RESP:** Wheezing

**SKIN:** Alopecia, diaphoresis, photosensitivity, pruritus, rash, urticaria

**Other:** **Angioedema**, **hypersensitivity reactions**, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm possibly increasing risk of congenital malformations.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug maybe present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Use imipramine cautiously in patients with a history of angle-closure glaucoma or urine retention because drug's anticholinergic effects may cause increased intraocular pressure and urine retention.

**WARNING** Know that MAO inhibitors should not be given within 2 weeks of imipramine, including intravenous methylene blue and linezolid. Patient may experience hypertensive crisis, seizures, and death.

**WARNING** Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. Notify prescriber immediately if serotonin syndrome is suspected because it can become life-threatening. Expect to discontinue imipramine therapy if serotonin syndrome is confirmed.

- Frequently assess for adverse reactions during first 2 hours of therapy.
- Check standing and supine blood pressure for orthostatic hypotension before and during imipramine therapy and before dosage increases.
- Anticipate increased risk of arrhythmias in patients with a history of cardiac disease.
- Know that when drug is used for depression, expect mood elevation to take 2 to 3 weeks. Watch patient closely for suicidal tendencies, especially children and adolescents and especially when therapy starts or dosage changes, because depression may worsen temporarily at these times.
- Avoid abrupt withdrawal of drug in patients on long-term therapy. Such withdrawal may cause headache, malaise, nausea, sleep disturbance, and vomiting.
- Taper drug gradually, as ordered, a few days before surgery to avoid risk of hypertension during surgery.
- Obtain CBC, as ordered, if patient experiences signs and symptoms of infection, such as fever or pharyngitis.
- Limit amount of drug given to potentially suicidal patient.

## PATIENT TEACHING

- Advise patient to take imipramine exactly as prescribed. Warn that stopping drug abruptly may cause headache, malaise, nausea, trouble sleeping, and vomiting.
- Caution parents to monitor child or adolescent closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Urge patient to report chills, dizziness, excess sedation, fever, palpitations, signs of allergic reaction, sore throat, and trouble urinating.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol during imipramine therapy because it increases alcohol effects and CNS depression.
- Suggest that patient eat frequent, small meals to help relieve nausea.
- Instruct patient to avoid prolonged exposure to sunlight because of the risk of photosensitivity.
- Inform male patient about possible impotence and decreased or increased libido.
- If patient reports dry mouth, suggest sugarless candy or gum to relieve it. Tell him to check with prescriber if dry mouth persists after 2 weeks.

## immune globulin intramuscular (human)

## Indications and Dosages

➤ *To treat primary immunodeficiency*

### **I.M. INJECTION (BAYGAM)**

**Adults.** 0.66 ml/kg (at least 100 mg/kg) every 3 to 4 wk; initial dose may be doubled.

### **I.V. INFUSION (GAMIMUNE N 5% S/D OR 10% S/D)**

**Adults.** 300 to 600 mg/kg every 3 to 4 wk.

### **I.V. INFUSION (GAMMAGARD S/D)**

**Adults.** 300 to 600 mg/kg every 3 to 4 wk. If response is inadequate, dose or frequency may be adjusted.

### **I.V. INFUSION (GAMMAR-P IV)**

**Adults.** 200 to 400 mg/kg every 3 to 4 wk.

**Adolescents and children.** 200 mg/kg every 3 to 4 wk.

### **I.V. INFUSION (GAMUNEX-C 10%)**

**Adults and children ages 2 and over.** 300 to 600 mg/kg every 3 or 4 wk.

### **I.V. INFUSION (IVEEGAM EN)**

**Adults.** 200 mg/kg every mo.

### **I.V. INFUSION (OCTAGAM 5%)**

**Adults.** *Initial:* 30 mg/kg/hr for first 30 min; increased, if tolerated, to 60 mg/kg/hr for second 30 min and, if tolerated, to 120 mg/kg/hr for another 30 min; followed by maintenance infusion of up to 200 mg/kg/hr.

### **I.V. INFUSION (CARIMUNE NF, NANOFILTERED)**

**Adults and children.** 0.4 to 0.8 g/kg once every 3 to 4 wk initially infused at 0.5 mg/kg/min. If tolerated, after 30 min, infusion rate increased to 1 mg/kg/min for 30 min. If tolerated, infusion rate gradually increased to maximum rate of 3 mg/kg/min. For patients at risk for renal dysfunction or thrombosis development, rate of infusion should be less than 2 mg/kg/min.

### **I.V. INFUSION (GAMMAPLEX 5% LIQUID)**

**Adults.** 300 to 800 mg/kg once every 3 to 4 wk, initially infused at 0.5 mg/kg/min and then gradually rate increased every 15 min, if tolerated, to final infusion rate of 4 mg/kg/min.

### **SUBCUTANEOUS INJECTION (GAMUNEX-C 10%, VIVAGLOBIN)**

**Adults.** Highly individualized and begun 1 wk after patient's last immune globulin intravenous (IGIV) infusion with initial weekly dosage obtained by multiplying the previous IGIV dose by 1.37; this number is then divided by the number of weeks between doses during the patient's previous IGIV treatment. Average weekly dose falls in the range of 100 to 200 mg/kg.

## **SUBCUTANEOUS INJECTION (GAMUNEX-C 10%)**

**Adults and children ages 2 and over.** Highly individualized and begun 1 wk after patient's last immune globulin intravenous (IGIV) infusion, with initial weekly dosage obtained by multiplying the previous IGIV dose in grams by 1.37; this number is then divided by the number of weeks between dosages during the patient's previous IGIV treatment.

## **SUBCUTANEOUS INJECTION (CUVITRU 20%)**

**Adults and children ages 2 and over.** Highly individualized and begun 1 wk after patient's last immune globulin intravenous (IGIV) infusion or adult's last immune globulin infusion 10% (human) with recombinant human hyaluronidase (HYQVIA), with initial weekly dosage obtained by dividing the previous IGIV or HYQVIA dose in grams by the number of weeks between intravenous doses, then multiplying this dose by 1.30.

- *To treat primary immunodeficiency disorders associated with defects in humoral immunity*

## **I.V. INFUSION (FLEBOGAMMA 5% DIF, FLEBOGAMMA 10% DIF, GAMMAGARD LIQUID)**

**Adults and children ages 2 and over.** 300 to 600 mg/kg every 3 to 4 wk.

## **I.V. INFUSION (PRIVIGEN)**

**Adults and children ages 3 and over.** 200 to 800 mg/kg every 3 to 4 wk.

## **I.V. INFUSION (BIVIGAM 10% LIQUID)**

**Adults.** 300 to 800 mg/kg every 3 to 4 wk. Infuse 0.5 mg/kg/min for the first 10 min, then increase infusion rate every 20 min, if tolerated, by 0.8 up to 6 mg/kg/min.

### **I.V. INFUSION (ASCENIV 10%)**

**Adults.** 300 to 800 mg/kg every 3 to 4 wk. 0.5 mg/kg infused for the first 15 min, then increased gradually every 15 min up to 8 mg/kg/min, if tolerated.

### **SUBCUTANEOUS INFUSION (HIZENTRA 20%, XEMBIFY 20%)**

**Adults and children age 2 and over.** Highly individualized and begun 1 wk after patient's last IGIV infusion with initial weekly dosage, obtained by multiplying the previous IGIV dose in grams by the dose adjustment factor of 1.37; this number is then divided by the number of weeks between doses during the patient's previous IGIV treatment, followed by multiplying the calculated dose by 5 to convert the dose calculated in grams to milliliters.

### **SUBCUTANEOUS INFUSION (GAMMAGARD LIQUID)**

**Adults and children age 2 and over.** Highly individualized and begun 1 wk after patient's last immune globulin intravenous (IGIV) infusion with initial weekly dosage obtained by multiplying the previous IGIV dose in grams by the dose adjustment factor of 1.37; this number is then divided by the number of weeks between doses during the patient's previous IGIV treatment, followed by multiplying the calculated dose by 10 to convert the dose calculated in grams to milliliters.

➤ *To treat idiopathic thrombocytopenic purpura (ITP)*

### **I.V. INFUSION (GAMIMUNE N 5% S/D)**

**Adults and children.** 400 mg/kg daily for 5 days. Or, 1,000 mg/kg for 1 or 2 days for patients not at risk for increased fluid volume.

### **I.V. INFUSION (PRIVIGEN)**

**Adults and adolescents age 15 and over.** 1 g/kg daily for 2 consecutive days for patients not at risk for increased fluid volume.

### **I.V. INFUSION (FLEBOGAMMA 10% DIF)**

**Adults and children ages 2 and over.** 1 g/kg daily for 2 consecutive days.

### **I.V. INFUSION (GAMIMUNE N 10% S/D)**

**Adults and children.** 1,000 mg/kg for 1 or 2 days for patients not at risk for increased fluid volume.

### **I.V. INFUSION (OCTAGAM 10%)**

**Adults.** 1 g/kg (10 ml/kg) daily for 2 consecutive days. Initially infuse at 0.01 ml/kg/min for 30 min. If tolerated, increase infusion rate to 0.02 ml/kg/min for next 30 min. If tolerated, further increase infusion rate to 0.04 ml/kg/min for 30 min. If tolerated, further increase infusion rate to 0.08 ml/kg/min for 30 min. If tolerated, infusion rate may be increased up to 0.12 mg/kg/min for remainder of infusion.

### **I.V. INFUSION (GAMUNEX-C 10%)**

**Adults.** 2 g/kg/dose.

### **I.V. INFUSION (CARIMUNE NF, NANOFILTERED)**

**Adults and children.** 0.4 g/kg on 2 to 5 consecutive days, initially infused at 0.5 mg/kg/min. If tolerated, after 30 min, infusion rate increased to 1 mg/kg/min for 30 min. If tolerated, infusion rate gradually increased to maximum rate of 3 mg/kg/min.

## **I.V. INFUSION (GAMMAPLEX 5% LIQUID)**

**Adults.** 1 g/kg on 2 consecutive days, initially infused at 0.5 mg/kg/min and then gradually rate increased every 15 min, if tolerated, to final infusion rate of 4 mg/kg/min.

**DOSAGE ADJUSTMENT** In acute ITP of childhood, I.V. Carimune NF therapy may be discontinued after second day of 5-day course if initial platelet count response is adequate (30,000 to 50,000/mm<sup>3</sup>). In chronic ITP, an additional I.V. infusion of 400 mg/kg (Carimune NF, or Gamimune) may be prescribed if platelet count falls below 30,000/mm<sup>3</sup> or if patient develops significant bleeding. If response remains inadequate, an additional I.V. infusion of 800 to 1,000 mg/kg may be given. In chronic ITP, dosage of Gammaplex 5% liquid may need to be reduced in patients at risk for thrombosis, hemolysis, acute kidney injury, or volume overload.

## **I.V. INFUSION (GAMMAGARD S/D)**

**Adults.** 1 g/kg. If response is inadequate, up to 3 separate doses may be administered on alternate days.

## **I.V. INFUSION (RHOPHYLAC)**

**Adults.** 50 mcg/kg at 2 ml/15 to 60 sec.

- *To treat acute or chronic pediatric ITP; to treat chronic adult-onset ITP; to treat pediatric- and adult-onset ITP secondary to HIV infection*

## **I.V. INJECTION (WINRHO SDF)**

**Adults and children.** *Initial:* 250 international units/kg given as a single injection over 3 to 5 min. Or, 125 international units/kg given as a single injection over 3 to 5 min and repeated once on a separate day. *Maintenance:* Frequency and dosage highly individualized based on patient's hemoglobin and platelet levels.

***DOSAGE ADJUSTMENT*** For patients with hemoglobin level less than 10 g/dl, dose reduced to 125 to 200 international units.

➤ *As adjunct to treat Kawasaki disease*

## **I.V. INFUSION (GAMMAGARD S/D)**

**Adults and adolescents.** 1 g/kg as a single dose; or, 400 mg/kg daily for 4 consecutive days.

➤ *To treat chronic inflammatory demyelinating polyneuropathy (CIDP)*

## **INTRAVENOUS INFUSION (GAMUNEX-C 10%)**

**Adults.** *Loading dose:* 2 g/kg. *Maintenance dose:* 1 g/kg.

## **INTRAVENOUS INFUSION (PRIVIGEN 10%)**

**Adults.** *Initial:* 2 g/kg given in divided doses over 2 to 5 consecutive days with each dose infused at a rate of 0.5mg/kg/min and, if tolerated, infusion rate gradually increased up to a maximum of 8 mg/kg/min. *Maintenance:* 1 g/kg as a single infusion or divided into 2 doses given on 2 consecutive days, every 3 wk for up to 6 months. Minimum infusion rate is 0.5 mg/kg/min and maximum infusion rate is 8 mg/kg/min.

## **SUBCUTANEOUS INFUSION (HIZENTRA 20%)**

**Adults.** 0.2 g/kg/wk administered in 1 or 2 sessions over 1 or 2 consecutive days.

**DOSAGE ADJUSTMENT** For patient receiving Hizentra in whom CIDP symptoms worsen, an IGIV-approved drug initiated while Hizentra is being discontinued. If patient improves and stabilizes during IGIV treatment, Hizentra may be reinitiated at a dose of 0.4 g/kg/wk administered in 2 sessions per wk over 1 or 2 days while IGIV therapy is being discontinued. If symptoms worsen on the 0.4 g/kg/wk dosage, drug discontinued.

- *To decrease the risk of graft-versus-host disease, interstitial pneumonia, septicemia, and other infections during first 100 days after bone marrow transplantation*

## **I.V. INFUSION (GAMIMUNE N 5% S/D OR 10% S/D)**

**Adults over age 20.** 500 mg/kg on 7th and 2nd days before transplant (or at time when conditioning therapy for transplantation begins), and then weekly through 90th day after transplant.

- *As adjunct to treat bacterial infections secondary to B-cell chronic lymphocytic leukemia*

## **I.V. INFUSION (GAMMAGARD S/D)**

**Adults and adolescents.** 400 mg/kg every 3 to 4 wk.

- *To prevent bacterial infection in children with HIV who are immunosuppressed*

## **I.V. INFUSION (GAMIMUNE N 5% S/D OR 10% S/D)**

**Children.** 400 mg/kg daily every 28 days.

- *To prevent hepatitis A*

### **I.M. INJECTION (BAYGAM)**

**Adults with household or institutional contacts.** 0.02 ml/kg (0.01 ml/lb).

**Adults traveling to areas where hepatitis A is common.** 0.02 ml/kg if staying less than 3 mo, 0.06 ml/kg (repeated every 4 to 6 mo) if staying 3 mo or longer.

### **I.M. INJECTION (GAMASTAN S/D)**

**Adults and children with household or institutional contacts.** 0.02 ml/kg.

**Adults traveling for less than 3 months to areas where hepatitis A is common.** 0.02 ml/kg.

**Adults traveling for 3 months or longer to areas where hepatitis A is common.** 0.06 ml/kg, repeated every 4 to 6 mo, as needed.

- *To prevent or lessen severity of measles (rubeola) in susceptible persons*

### **I.M. INJECTION (BAYGAM)**

**Adults exposed fewer than 6 days previously.** 0.25 ml/kg (0.11 ml/lb).

### **I.M. INJECTION (GAMASTAN S/D)**

**Adults and children exposed fewer than 6 days previously.** 0.25 ml/kg (0.11 ml/lb).

**Children exposed to rubeola and are immunocompromised.** 0.5 ml/kg immediately. *Maximum:* 15 ml dose.

- *To provide passive immunization against varicella in immunosuppressed patients*

## **I.M. INJECTION (BAYGAM, GAMASTAN S/D)**

**Adults.** 0.6 to 1.2 ml/kg if varicella-zoster immune globulin (human) is unavailable.

- *To improve muscle strength and disability as maintenance therapy in patients with multifocal motor neuropathy*

## **I.V. INFUSION (GAMMAGARD LIQUID)**

**Adults.** *Maintenance:* 0.5 to 2.4 g/kg/mo. Initially infused at 0.5 ml/kg/hr (0.8 mg/kg/min) with rate increased, as needed, up to 5.4 ml/kg/hr (9 mg/kg/min).

- *To reduce the risk of infection and fetal damage in women who have been exposed to rubella in early pregnancy*

## **I.M. INJECTION (BAYGAM, GAMASTAN S/D)**

**Adults.** 0.55 ml/kg.

- *To suppress Rh isoimmunization*

## **I.M. INJECTION, I.V. INFUSION (RHOPHYLAC)**

**Adult pregnant women.** 1,500 international units as a single dose at 28- to 30-wk gestation, followed by 1,500 international units within 72 hr after delivery of an Rh-positive newborn.

## **I.M. INJECTION (WINRHO SDF)**

**Adult pregnant women.** 1,500 international units as a single dose at 28-wk gestation, followed by 600 international units within 72 hr after delivery of an Rh-positive newborn.

## **I.V. INJECTION (WINRHO SDF)**

**Adult pregnant women.** 1,500 international units as a single dose infused at a rate of 2 ml/5 to 15 sec at 28-wk gestation, followed by 600 international units infused at a rate of 2 ml/5 to 15 sec within 72 hr after delivery of an Rh-positive newborn.

**DOSAGE ADJUSTMENT** For patients with more than 34-wk gestation and having an abortion, amniocentesis, or other manipulative procedure, 600 international units given within 72 hr but preferably immediately after procedure. For patients with 34-wk gestation or less and having amniocentesis or chorionic villus sampling, 1,500 international units given immediately after procedure and repeated every 12 wk for duration of pregnancy. For patients with threatened abortion at any stage of pregnancy, 1,500 international units given immediately.

➤ *To treat incompatible blood transfusions*

## **I.M. INJECTION, I.V. INFUSION (RHOPHYLAC)**

**Adults exposed to Rh-positive RBCs.** 100 international units/2 ml transfused blood or per 1 ml erythrocyte concentrate within 72 hr of exposure.

## **I.M. INJECTION (WINRHO SDF)**

**Adults exposed to Rh-positive whole blood.** 6,000 international units every 12 hr until total dose (60 international units/ml of blood) is given.

**Adults exposed to Rh-positive RBCs.** 6,000 international units every 12 hr until total dose (120 international units/ml of cells) is given.

## **I.V. INJECTION (WINRHO SDF)**

**Adults exposed to Rh-positive whole blood.** 3,000 international units infused at a rate of 2 ml/5 to 15 sec

every 8 hr until total dose (45 international units/ml of blood) is given.

**Adults exposed to Rh-positive RBCs.** 3,000 international units infused at a rate of 2 ml/5 to 15 sec every 8 hr until total dose (90 international units/ml of cells) is given.

➤ *To treat massive fetomaternal hemorrhage*

## **I.M. INJECTION, I.V. INFUSION (RHOPHYLAC)**

**Adults exposed to Rh-positive RBCs.** 1,500 international units plus 100 international units for every 1 ml of fetal RBCs exceeding 15 ml if transplacental bleeding is quantified, or an additional 1,500 international units if transplacental bleeding can't be quantified within 72 hr of hemorrhage.

## **I.M. INJECTION (WINRHO SDF)**

**Adults exposed to Rh-positive whole blood.** 6,000 international units every 12 hr until total dose (60 international units/ml of blood) is given.

**Adults exposed to Rh-positive RBCs.** 6,000 international units every 12 hr until total dose (120 international units/ml of cells) is given.

## **I.V. INJECTION (WINRHO SDF)**

**Adults exposed to Rh-positive whole blood.** 3,000 international units infused at a rate of 2 ml/5 to 15 sec every 8 hr until total dose (45 international units/ml of blood) is given.

**Adults exposed to Rh-positive RBCs.** 3,000 international units infused at a rate of 2 ml/5 to 15 sec every 8 hr until total dose (90 international units/ml of cells) is given.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
I.M.	Unknown	Unknown	Unknown
I.V.	Unknown	Unknown	21-28 days
SubQ	Unknown	Unknown	Unknown

## Mechanism of Action

Releases antibody-specific globulins to produce an antibody-antigen reaction that results in bacterial lysis and facilitates bacterial phagocytosis. In treatment of ITP, immune globulin blocks iron receptors on macrophages to increase immunoglobulin action. Immune globulin also increases cytokine production and improves B-cell immune function by regulating macrophage and T-cell activity. Newly formed antigen-antibody complexes produce split complement components that cause bacterial lysis.

In Kawasaki disease and bacterial infections with B-cell chronic lymphocytic leukemia, immune globulin neutralizes bacterial and viral toxins that harm immune and inflammatory responses.

## Incompatibilities

Don't mix immune globulin with any other drugs, including other immune globulins, or with any I.V. solutions other than D<sub>5</sub>W or manufacturer's supplied diluent because effects of doing so are unknown.

## Contraindications

Hypersensitivity to immune globulin (human) or its components; IgA deficiency in patients with known antibody to IgA

# Interactions

## DRUGS

*live-virus vaccines*: Possibly decreased response to vaccine

## Adverse Reactions

**CNS:** **Aseptic meningitis** (rare), headache, malaise

**CV:** Chest discomfort, hypertension, tachycardia, **thrombotic events**, **volume overload**

**EENT:** Blurred vision, oropharyngeal pain

**GI:** Nausea, vomiting

**GU:** **Acute renal dysfunction or failure**, osmotic nephrosis

**HEME:** **Acute hemolysis**, **delayed hemolytic anemia**, **disseminated intravascular coagulation (DIC)**, positive Coombs' test

**MS:** Arthralgia, back or extremity pain, muscle spasms or weakness, myalgia

**RESP:** Dyspnea, **pulmonary edema or embolism**

**Other:** Hyperproteinemia, **hyponatremia**, increased serum viscosity

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm although immune globulins increasingly cross the placental barrier after 30 weeks gestation.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that before giving immune globulin, monitor patient's fluid volume and BUN and serum creatinine levels, as ordered, to determine risk for acute renal failure. Those at increased risk include patients with diabetes mellitus, paraproteinemia, renal insufficiency, sepsis, or volume depletion; those taking nephrotoxic drugs; and those over age 65. Expect drug to be discontinued if renal function deteriorates.
- Use caution when administering immune globulin, regardless of the route of administration, because of risk for thrombosis. Monitor closely patients with increased risk of thrombosis such as advanced age, coagulation disorders, a history of atherosclerosis, impaired cardiac output, multiple cardiovascular risk factors, or prolonged periods of immobilization, and/or hyperviscosity. In such patients, obtain a baseline assessment of blood viscosity, as ordered. Ensure patient is adequately hydrated prior to administration. When administering drug intravenously, expect to infuse at the lowest rate possible. Report any signs and symptoms suggestive of a thrombotic event immediately to prescriber and be prepared to administer treatment, as ordered.
- Keep in mind when preparing immune globulin, verify that appropriate form is being used—either immune globulin intramuscular for I.M. injection, immune globulin intravenous for I.V. infusion or immune globulin subcutaneous for subcutaneous infusion.
- To reconstitute drug if required, follow manufacturer's guidelines and use only diluent recommended by manufacturer. Don't shake solution; excessive shaking causes foaming. If drug or diluent is cold, drug may take up to 20 minutes to dissolve.
- Know that if drug reconstituted outside of sterile laminar airflow conditions, administer it immediately and discard unused portions.
- Be aware that an in-line filter may be required for intravenous infusion of drug. Check manufacturer's guidelines for specific product being used.
- Consult manufacturer's guidelines to determine appropriate flow rate for starting infusion. Expect to increase flow rate after 15 to 30 minutes, as specified, except for Hizentra 20%, which has a flow adjustment rate done after the first infusion is completed and Privigen, which may adjust flow rate, as needed.
- Be aware that when giving drug by I.M. injection, inject it only into deltoid muscle of upper arm or anterolateral aspect of upper thigh. If giving a dose larger than 5 ml, divide it and administer at separate sites.
- Know that when giving Hizentra by subcutaneous infusion, infuse in the abdomen, lateral hip, thigh, or upper arm with no more than 4 sites used simultaneously. Infusion sites should be at least 2 inches apart and sites changed with each weekly administration. For first infusion, do not infuse

more than 15 ml/hr/site. The volume may be increased to 20 ml/hr/site after the fourth infusion and to a maximum of 25 ml/hr/site as tolerated. However, do not exceed a maximum flow rate of more than a total of 50 ml/hr for all sites combined at any time. Use an infusion pump to administer the drug.

- Keep in mind when giving Gamunex-C by subcutaneous infusion, infuse in the abdomen, lateral hip, thigh, or upper arm with no more than 8 sites used simultaneously. Infusion sites should be at least 2 inches apart and sites changed with each weekly administration. Be aware that the average infusion rate for Gamunex-C as a subcutaneous infusion is 20 ml/hr/site. Know that if dilution is required, Gamunex-C is not compatible with saline. It may be diluted with 5% dextrose in water. Content of Gamunex-C vials may be pooled under aseptic conditions into sterile infusion bags and infused within 8 hours after pooling. Use an infusion pump to administer the drug.
- Administer Vivaglobin by subcutaneous injection into patient's abdomen, lateral hip, thighs, or upper arms. Rotate injection sites weekly. Never inject intravenously.
- Watch for an acute inflammatory reaction in patients who have never received immune globulin therapy before, in those whose last treatment was more than 8 weeks before, and in those whose initial infusion rate exceeded 1 ml/min. Within 30 minutes to 1 hour after beginning infusion, assess for chills, diaphoresis, dizziness, facial flushing, feeling of tightness in chest, fever, hypotension, nausea, and vomiting. Notify prescriber immediately if such symptoms occur, and be prepared to stop infusion until symptoms have subsided.
- Monitor patient closely for signs and symptoms of hemolysis, especially patients with risk factors. For patients at increased risk, expect to obtain a baseline measurement of hematocrit or hemoglobin prior to infusion and within 36 to 96 hours post infusion. Notify prescriber of any abnormalities.

**WARNING** Be aware that after immune globulin administration, monitor patient closely for aseptic meningitis. Notify prescriber if patient develops drowsiness, fever, nausea, nuchal rigidity, painful eye movements, photophobia, severe headache, or vomiting.

- Be aware that immune globulin intravenous is made from human plasma and therefore may contain infectious agents, such as viruses. Risk of transmitting a virus by infusion has been reduced by inactivating or

removing certain viruses from the product, screening blood donors, or testing donated blood.

- Monitor patient with preexisting renal insufficiency who is receiving Bivigam to be sure the patient is not volume-depleted. If renal function deteriorates, notify prescriber and expect drug to be discontinued. For the patient at risk for renal dysfunction or thrombotic events, administer Bivigam at the minimum infusion rate practicable.
- Be aware that for patient receiving WinRho SDF to treat ITP, assess clinical response by monitoring patient's hemoglobin level, platelet count, RBC count, and reticulocyte level.
- Be aware that for patient receiving WinRho SDF for exposure to incompatible blood transfusions or massive fetal hemorrhage, give drug within 72 hours of incident, as ordered.

## PATIENT TEACHING

- Instruct patient to report immediately any symptoms he experiences after receiving immune globulin.
- Inform patient to postpone live-virus vaccinations for up to 11 months after receiving immune globulin because drug may delay or inhibit response to vaccine.

## indacaterol maleate

### Arcapta Neohaler

## Class and Category

*Pharmacologic class:* Long-acting beta<sub>2</sub>-adrenergic agonist

*Therapeutic class:* Bronchodilator

## Indications and Dosages

- *To alleviate airflow obstruction in patients with chronic obstructive pulmonary disease (COPD), including chronic bronchitis and/or emphysema*

## **INHALATION AEROSOL**

**Adults.** 75 mcg once daily.

## **Mechanism of Action**

Selectively attaches to beta<sub>2</sub> receptors on bronchial membranes, stimulating the intracellular enzyme adenyl cyclase to convert adenosine triphosphate to cAMP. The resulting increase in the intracellular cAMP level relaxes bronchial smooth-muscle cells, which allows greater airflow through the airways.

## **Contraindications**

Hypersensitivity to indacaterol or its components; presence of asthma without use of an inhaled corticosteroid

## **Interactions**

### **DRUGS**

*adrenergic drugs:* Potentiated sympathetic effects

*beta blockers:* Possible interference with the effect of beta blockers and indacaterol

*diuretics, steroids, xanthine derivatives:* Possible increased risk of hypokalemic effect

*MAO inhibitors, tricyclic antidepressants:* Potentiated adrenergic action on the cardiovascular system

*non-potassium sparing diuretics:* Increased risk of ECG changes or hypokalemia

*QT prolonging drugs:* Increased risk of ventricular arrhythmias

## Adverse Reactions

**CNS:** Dizziness, headache, nervousness, tremor

**CV:** Angina, **atrial fibrillation**, peripheral edema, palpitations, tachycardia

**EENT:** Nasopharyngitis, oropharyngeal pain, sinusitis

**ENDO:** Hyperglycemia

**GI:** Nausea

**MS:** Muscle spasm, musculoskeletal pain

**RESP:** COPD exacerbation, cough, dyspnea, **paradoxical bronchospasm**, pneumonia, upper respiratory tract infection

**SKIN:** Pruritus, rash, urticaria

**Other:** **Angioedema**, **hypokalemia**, **immediate hypersensitivity reactions**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- There is the potential that drug may interfere with uterine contractions because it is a beta-agonist.
- Use of drug during labor and delivery should be restricted to those patients in whom the benefits clearly outweigh the risks.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that indacaterol should not be given to patients with acutely deteriorating COPD nor should it be used for relief of acute symptoms. Instead acute symptoms should be treated with an inhaled short-acting beta<sub>2</sub>-agonist.

**WARNING** Know that indacaterol is not used to treat asthma but may be used in patients with asthma who also have COPD as long as the patient is also receiving inhaled corticosteroid therapy. This is because the use of long-acting beta<sub>2</sub>-adrenergic agonists such as indacaterol without inhaled corticosteroid therapy in patients with asthma, increases the risk of serious asthma-related events requiring hospitalization and intubation and possibly ending in death.

- Use cautiously in patients with cardiovascular disorders, especially cardiac arrhythmias, coronary insufficiency, and hypertension because drug can increase blood pressure, pulse rate, and cause ECG changes, such as flattening of the T wave, prolongation of the QT interval, and ST segment depression.
- Use cautiously in patients with convulsive disorders or thyrotoxicosis, or in patients who are unusually responsive to sympathomimetic amines as drug may aggravate these conditions.
- Monitor the patient's vital signs for an increase in blood pressure or pulse rate. If such effects occur, notify prescriber as indacaterol may need to be discontinued.

**WARNING** Monitor patient for immediate hypersensitivity reactions after administering indacaterol that may include difficulties in breathing or swallowing; rash; swelling of face, lips, and tongue; or urticaria. If present, discontinue drug immediately, notify prescriber, and provide supportive care, as indicated.

## PATIENT TEACHING

- Instruct patient who has been taking inhaled, short-acting beta<sub>2</sub>-agonists on a regular basis to discontinue the regular use of these drugs, as directed by prescriber, and use them only for symptomatic relief of acute respiratory symptoms, as ordered.
- Tell patient indacaterol capsules are only for use in inhaler device and should never be swallowed.
- Instruct patient to store capsules in their original packaging and to open immediately before use.
- Teach patient how to use delivery system. Tell them to place capsule in well of inhaler device and then to press and release buttons on side of device only once to pierce capsule. A click-type of sound will occur. Have patient place the inhaler into his mouth with the buttons to the left and right (not up and down). Then have him inhale rapidly and deeply through mouthpiece; drug is dispersed into airways as patient inhales. A whirring noise should be heard when inhaling. If not, the capsule may be stuck in the capsule cavity. If this occurs, have the patient open the inhaler and carefully loosen the capsule by tapping the base of the device. Tell him not to press the piercing buttons to loosen the capsule. Have him repeat these steps, if needed.
- Remind patient that indacaterol is not to be used to relieve acute symptoms. Instead, he should use his short-acting beta<sub>2</sub>-agonist.
- Inform patient to notify prescriber if any of the following situations occur: if indacaterol no longer seems to control his symptoms, if he needs to use his short-acting beta<sub>2</sub>-agonist more often than usual; or if the short-acting beta<sub>2</sub>-agonist becomes less effective.

## indapamide

### **Gen-Indapamide (CAN), Lozide (CAN)**

## **Class and Category**

*Pharmacologic class:* Thiazide-like diuretic

*Therapeutic class:* Diuretic

## Indications and Dosages

➤ *To treat edema caused by heart failure*

### **TABLETS**

**Adults.** 2.5 mg daily in the morning, increased to 5 mg daily after 1 wk, if indicated.

➤ *To manage hypertension*

### **TABLETS**

**Adults. Initial:** 1.25 mg daily, increased to 2.5 mg daily after 4 wk, if needed. Increased to 5 mg daily after additional 4 wk, if needed.

Route	Onset	Peak	Duration
P.O.*	1-2 hr	Unknown	36 hr
P.O.†	1-2 wk	8-12 wk	Up to 8 wk

\* For edema.

† For hypertension (with multiple doses).

## Mechanism of Action

Acts mainly on distal convoluted tubules, where it enhances excretion of chloride, sodium, and water by inhibiting sodium ion movement across renal tubules. The resulting decrease in extracellular fluid volume and plasma decreases peripheral vascular resistance and reduces blood pressure. This thiazide diuretic also may cause arterial vasodilation by blocking calcium channels in smooth-muscle cells.

# Contraindications

Anuria; hypersensitivity to indapamide, sulfonamide-derived drugs, or their components

# Interactions

## DRUGS

*lithium*: Increased risk of lithium toxicity

*norepinephrine*: Decreased arterial responsiveness to norepinephrine

*other antihypertensives*: Increased risk of hypotension

# Adverse Reactions

**CNS**: Anxiety, dizziness, drowsiness, fatigue, fever, headache, mood changes, nervousness, sleep disturbance, vertigo, weakness

**CV**: **Arrhythmias**, hypercholesterolemia, orthostatic hypotension, palpitations

**EENT**: Dry mouth

**ENDO**: Hyperglycemia, **hypoglycemia**

**GI**: Anorexia, constipation, diarrhea, **hepatitis**, jaundice, nausea, **pancreatitis**, thirst, vomiting

**GU**: Impotence, nocturia

**MS**: Gout, muscle spasms

**SKIN**: Necrotizing vasculitis, photosensitivity, pruritus, rash, urticaria

**Other**: Dilutional hyponatremia and hyponatremia, **hypokalemia**, **metabolic alkalosis**, weight loss

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm. However, diuretics are known to cross the placental barrier and may cause fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

## **Nursing Considerations**

- Administer indapamide with food or milk to reduce adverse GI reactions.
- Give drug early in the day to avoid nocturia.
- Weigh patient daily, and monitor blood pressure, fluid intake and output, and serum electrolyte levels, especially in elderly women, because severe hypokalemia and hyponatremia may occur. Report electrolyte abnormalities, and expect to provide corrective measures, as prescribed.
- Monitor BUN and serum creatinine levels regularly, as ordered.
- Know that if muscle cramps and weakness develop from hypokalemia, expect prescriber to order potassium-sparing diuretic or potassium supplement.
- Be aware that when managing hypertension, expect therapeutic response to indapamide to take several weeks.

## **PATIENT TEACHING**

- Advise patient to take indapamide early in the day to avoid nighttime urination and to take it with food or milk to minimize GI distress.
- Encourage patient to eat high-potassium foods, such as bananas and oranges.
- Caution patient to change position slowly to minimize effects of orthostatic hypotension.

- Instruct patient to weigh himself daily at the same time and wearing similar clothing. Direct him to report a weight gain of more than 0.9 kg (2 lb) per day or 2.3 kg (5 lb) per week.
- Inform patient about possible photosensitivity.
- Suggest sugarless gum or hard candy if patient has a dry mouth.

# indinavir

## Crixivan

### Class and Category

*Pharmacologic class:* Protease inhibitor

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV) infection*

#### CAPSULES

**Adults.** 800 mg every 8 hr given 1 hr before or 2 hr after a meal.

***DOSAGE ADJUSTMENT*** For patient who has mild to moderate hepatic insufficiency due to cirrhosis and for patients who are taking delavirdine at a dosage of 400 mg three times daily, itraconazole at a dosage of 200 mg twice daily, or ketoconazole, dosage reduced to 600 mg every 8 hr. For patients taking rifabutin concomitantly, dosage increased to 1000 mg every 8 hr with rifabutin dosage reduced by half.

## Mechanism of Action

Binds to the protease active site to inhibit the activity of the HIV-1 protease enzyme. This inhibition prevents cleavage of the viral polyproteins, resulting in the formation of immature noninfectious viral particles.

## Contraindications

Concurrent therapy with alfuzosin, alprazolam, amiodarone, cisapride, dihydroergotamine, ergonovine, ergotamine, lovastatin, methylergonovine, midazolam (oral), pimozone, sildenafil (when used to treat pulmonary arterial hypertension), simvastatin, or triazolam; hypersensitivity to indinavir or its components

## Interactions

### DRUGS

*alfuzosin*: Possibly increased alfuzosin concentrations leading to hypotension

*alprazolam, midazolam (oral), triazolam*: Possible risk of increased or prolonged respiratory depression or sedation

*amiodarone, cisapride*: Increased risk for serious or life-threatening adverse reactions such as cardiac arrhythmias

*atazanavir*: Increased risk of unconjugated hyperbilirubinemia

*atorvastatin, bepridil, bosentan, calcium channel blockers, colchicine, fluticasone, lidocaine (systemic), midazolam (parenteral), quetiapine, quinidine, rosuvastatin, trazodone*: Increased concentration of these drugs

*carbamazepine, efavirenz, nevirapine, phenobarbital, phenytoin, venlafaxine*: Decreased indinavir concentration, lowering effectiveness

*clarithromycin*: Increased concentrations of both clarithromycin and indinavir  
*cyclosporine, sirolimus, tacrolimus*: Increased immunosuppressant effects  
*delavirdine, itraconazole, ketoconazole, nelfinavir, ritonavir, saquinavir*: Increased indinavir concentration, increasing risk of adverse reactions  
*didanosine*: Possibly interference with absorption of indinavir  
*dihydroergotamine, ergonovine, ergotamine, methylergonovine*: Possible acute ergot toxicity  
*lovastatin, simvastatin*: Increased risk of myopathy and rhabdomyolysis  
*lurasidone, pimozide*: Possibly increased risk of serious or life-threatening adverse reactions  
*rifabutin*: Decreased indinavir concentration and effectiveness; increased rifabutin concentration and possibly adverse reactions  
*rifampin, St. John's wort*: Possible loss of virologic response and resistance to indinavir  
*salmeterol*: Possibly increased risk of cardiovascular adverse effects such as palpitations, prolonged QT, and sinus tachycardia  
*sildenafil (used to treat of pulmonary arterial hypertension), tadalafil, vardenafil*: Possible increased risk of PDE5-inhibitor-induced adverse reactions such as hypotension, prolonged erection, syncope, and visual disturbances

## **Adverse Reactions**

**CNS**: Asthenia, **cerebrovascular disorders**, depression, dizziness, fatigue, fever, headache, malaise, somnolence

**CV**: Angina pectoris, elevated cholesterol and triglyceride levels, **MI**, vasculitis

**EENT:** Oral paresthesia, pharyngitis, taste perversion

**ENDO:** Cushingoid appearance, exacerbation of preexisting diabetes mellitus, fat redistribution, hyperglycemia, new-onset diabetes mellitus

**GI:** Abdominal distention or pain, acid regurgitation, anorexia, diarrhea, dyspepsia, elevated amylase or liver enzymes, **hepatic dysfunction or failure, hepatitis, hyperbilirubinemia, increased appetite, jaundice, nausea, pancreatitis**, vomiting

**GU:** **Acute renal failure**, dysuria, elevated creatinine level, flank pain, hematuria, interstitial nephritis, leukocyturia, nephrolithiasis, pyelonephritis, **renal insufficiency**, urolithiasis

**HEME:** **Acute hemolytic anemia**, anemia, decreased hemoglobin, **neutropenia, spontaneous bleeding in patients with hemophilia, thrombocytopenia**

**MS:** Arthralgia, back pain, periarthritides

**RESP:** Cough, dyspnea, shortness of breath, upper respiratory infection

**SKIN:** Alopecia, dry skin, **erythema multiforme**, hyperpigmentation, paronychia, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Anaphylaxis**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Review patient's drug history before starting indinavir therapy, because drug interacts with many other drugs, some of which are contraindicated during indinavir use.
- Administer indinavir 1 hour before or 2 hours after a meal. Know that drug can be administered with other liquids such as coffee, juice, skim milk, or tea or with a light meal (such as dry toast with jelly or corn flakes with skim milk and sugar). Know that a meal high in calories, fat, and protein reduces the absorption of indinavir.
- Monitor patient for signs and symptoms of nephrolithiasis or urolithiasis, such as flank pain with or without hematuria. Notify prescriber if patient complains of flank pain or exhibits hematuria. Expect drug to be temporarily stopped for up to 3 days or discontinued. Ensure that patient receives adequate hydration throughout therapy.
- Monitor patient's complete blood count, because acute hemolytic anemia has occurred with indinavir therapy, ending in death for some patients. Report any change in complete blood count and signs and symptoms of anemia to prescriber. Be prepared to provide supportive care as ordered. Expect indinavir to be discontinued.
- Monitor patient's liver enzymes and assess patient for signs and symptoms of liver dysfunction, because hepatitis including hepatic failure has occurred with indinavir therapy.
- Check patient's blood glucose levels routinely, because indinavir therapy may cause hyperglycemia and exacerbate glucose control in patients with diabetes or even induce diabetes mellitus in patients not diagnosed with diabetes mellitus before therapy was begun.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including indinavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders

such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

- Perform a urinalysis periodically, as ordered. Notify prescriber if leukocyturia occurs, as further evaluation and possible discontinuation of indinavir may be needed.

## **PATIENT TEACHING**

- Instruct patient to take indinavir 1 hour before or 2 hours after a meal. Tell patient that alternatively, she may take the drug with other liquids such as coffee, juice, skim milk, or tea, or with a light meal such as dry toast with jelly or corn flakes with skim milk and sugar.
- Tell patient to store drug in original container and that the desiccant should remain in the bottle because the capsules are sensitive to moisture.
- Inform patient that she must maintain adequate hydration throughout therapy. She should drink at least 48 ounces of liquids daily.
- Instruct patient who is also taking didanosine to take the two drugs 1 hour apart on an empty stomach.
- Advise patient to notify all prescribers of indinavir therapy, because of potential drug interactions, and advise patient not to take over-the-counter preparations (including herbal drugs and preparations) without consulting prescriber first.
- Warn male patient of the danger of taking drugs used to treat erectile dysfunction, because very serious adverse reactions can occur if taken with indinavir.
- Inform patient that indinavir therapy may cause changes in her body appearance because of fat redistribution. Prepare her for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Encourage women of childbearing age to report known or suspected pregnancy.
- Alert mothers that breastfeeding is not recommended during indinavir therapy.
- Inform patients with hemophilia that indinavir may cause spontaneous bleeding and to seek immediate medical attention if bleeding occurs.

# indomethacin

**Indocid (CAN), Indocin, Indocin SR,  
Indo-Lemmon, Nu-Indo (CAN),  
Tivorbex**

# indomethacin sodium trihydrate

**Indocin I.V.**

## Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic

## Indications and Dosages

- *To relieve moderate to severe symptoms of ankylosing spondylitis, osteoarthritis, and rheumatoid arthritis*

## CAPSULES, ORAL SUSPENSION

**Adults and adolescents over age 14.** 25 mg twice daily or three times daily, increased by 25 or 50 mg daily every wk, as needed. *Maximum:* 200 mg daily. After adequate response, dosage reduced as low as possible.

## E.R. CAPSULES

**Adults and adolescents over age 14.** 75 mg daily, increased to 75 mg twice daily, if needed.

## **SUPPOSITORIES**

**Adults and adolescents over age 14.** 50 mg up to four times daily.

- *To relieve symptoms of acute gouty arthritis*

## **CAPSULES, ORAL SUSPENSION, SUPPOSITORIES**

**Adults.** 50 mg three times daily until gout attack relieved and then drug rapidly reduced to complete cessation.

- *To treat inflammation and relieve acute shoulder pain from bursitis or tendinitis*

## **CAPSULES, ORAL SUSPENSION**

**Adults and adolescents over age 14.** 75 to 150 mg daily in divided doses three times daily or four times daily for 7 to 14 days.

## **E.R. CAPSULES**

**Adults and adolescents over age 14.** 75 mg once or twice daily for 7 to 14 days.

## **SUPPOSITORIES**

**Adults and adolescents over age 14.** 50 mg up to four times daily for 7 to 14 days. *Maximum:* 200 mg daily.

- *To treat mild to moderate acute pain*

## **CAPSULES (TIVORBEX)**

**Adults.** 20 mg three times daily or 40 mg two or three times daily.

**DOSAGE ADJUSTMENT** Dosage reduced for elderly patients.

- *To treat hemodynamically significant patent ductus arteriosus in premature infants weighing 500 to 1,750 g (1 to 3.9 lb)*

## I.V. INFUSION

**Infants over age 7 days.** *Initial:* 200 mcg/kg (0.2 mg/kg) over 20 to 30 min; 2 additional doses of 250 mcg/kg (0.25 mg/kg) given at 12- to 24-hr intervals. A second course may be repeated if ductus arteriosus reopens.

**Neonates ages 2 to 7 days.** *Initial:* 200 mcg/kg (0.2 mg/kg) over 20 to 30 min; 2 additional doses of 200 mcg/kg (0.2 mg/kg) given at 12- to 24-hr intervals. A second course may be repeated if ductus arteriosus reopens.

**Neonates under age 48 hours.** *Initial:* 200 mcg/kg (0.2 mg/kg) over 20 to 30 min; 2 additional doses of 100 mcg/kg (0.1 mg/kg) given at 12- to 24-hr intervals. A second course may be repeated if ductus arteriosus reopens.

Route	Onset	Peak	Duration
P.O.*	2-4 hr	2-5 days	Unknown
P.O.†	30 min	Unknown	4-6 hr
P.O.‡	In 7 days	1-2 wk	Unknown

\* For antigout effects.

† For anti-inflammatory effects.

‡ For antirheumatic effects.

## Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate inflammatory response and cause local vasodilation, pain, and swelling. By blocking cyclooxygenase and inhibiting prostaglandins,

this NSAID reduces inflammatory symptoms and helps relieve pain.

## Incompatibilities

Don't give indomethacin suspension with alkaline antacids or liquids. Don't mix reconstituted indomethacin sodium with other I.V. infusion solutions.

## Contraindications

History of asthma, urticaria, or other allergic-type reactions after taking aspirin or other NSAIDs; hypersensitivity to indomethacin, other NSAIDs, or their components; history of proctitis or recent rectal bleeding (suppositories); postoperative pain with coronary artery bypass graft (CABG) surgery

## Interactions

### DRUGS

*Note:* All effects listed are for oral forms and suppositories unless indicated.

*angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs), or beta-blockers (including propranolol):* Decreased antihypertensive effects of these drugs; in the elderly or patients with renal impairment or who are volume-depleted, increased risk of acute renal failure

*anticoagulants such as warfarin, antiplatelets such as aspirin, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors:* Increased risk of serious bleeding

*aspirin, other NSAIDs, other salicylates*: Increased risk of adverse GI effects and non-GI bleeding

*cyclosporine*: Increased risk of nephrotoxicity

*digoxin*: Increased blood digoxin level and risk of digitalis toxicity (all forms)

*diuretics (loop, potassium-sparing, and thiazide)*:

Decreased antihypertensive and diuretic effects; increased risk of hyperkalemia with potassium-sparing diuretics

*lithium*: Increased blood lithium level and risk of toxicity

*methotrexate*: Increased risk of methotrexate toxicity

*pemetrexed*: Increased risk of myelosuppression; increased risk of GI and renal toxicity

*probenecid*: Increased blood level and effectiveness of indomethacin, increased risk of indomethacin toxicity

## ACTIVITIES

*alcohol use*: Increased risk of adverse GI effects

## Adverse Reactions

*Note*: All reactions are for oral forms and suppositories unless indicated.

**CNS**: Confusion, **CVA**, depression, dizziness, drowsiness, fatigue, hallucinations, headache, **intraventricular hemorrhage (I.V.)**, peripheral neuropathy, **seizures**, syncope, vertigo

**CV**: **Arrhythmias**, chest pain, edema, fluid retention (all forms), **heart failure**, hypertension, **MI**, **pulmonary hypertension (I.V.)**, tachycardia

**EENT**: Blurred vision, corneal and retinal damage, epistaxis, hearing loss, stomatitis, tinnitus

**ENDO**: **Hypoglycemia (I.V.)**

**GI**: Abdominal cramps or pain, abdominal distention (I.V.), anorexia, constipation, diarrhea, diverticulitis, dyspepsia,

dysphagia, elevated liver enzymes, epigastric discomfort, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, **GI bleeding** and ulceration (all forms), hemorrhoids, **hepatic dysfunction (I.V.)**, **hepatic failure**, hiatal hernia, ileus (I.V.), indigestion, **melena**, nausea, **necrotizing enterocolitis (I.V.)**, **pancreatitis**, peptic ulcer, **perforation of intestine or stomach**, vomiting (all forms)

**GU:** **Acute renal failure**, hematuria, interstitial nephritis, **nephrotic syndrome**, oliguria (I.V.), proteinuria, renal dysfunction (I.V.), vaginal bleeding

**HEME:** **Agranulocytosis**, anemia, **aplastic anemia**, **bone marrow depression**, **decreased platelet aggregation (I.V.)**, **disseminated intravascular coagulation (DIC)**, **hemolytic anemia**, iron deficiency anemia, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**, **unusual bleeding** or bruising (all forms)

**RESP:** **Asthma**, **respiratory depression**

**SKIN:** Ecchymosis, **erythema multiforme**, erythema nodosum, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia (I.V.)**, **hyponatremia (I.V.)**, injection-site irritation

## Childbearing Considerations

### PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

## **LACTATION**

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **REPRODUCTION**

- Drug may delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in some women.

## **Nursing Considerations**

- Be aware that NSAIDs like indomethacin should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Know that the risk of heart failure increases with indomethacin use because it is a NSAID. This class of drugs should not be used in patients with severe heart failure but, if unavoidable, monitor patient for worsening of heart failure.
- Use indomethacin with extreme caution in patients with history of GI bleeding or ulcer disease because NSAIDs, such as indomethacin, increase risk of GI bleeding and ulceration. Expect to use drug for shortest time possible in these patients.
- Be aware that serious GI tract, bleeding, perforation, and ulceration may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give oral indomethacin with an antacid, food, or a full glass of water (not suspension), to reduce GI distress.
- Know that if GI distress occurs, withhold drug and notify prescriber immediately.
- Use indomethacin cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.
- Shake suspension well before giving it.
- Make sure suppository stays in rectum at least 1 hour to improve absorption.

- To reconstitute I.V. form, add 1 to 2 ml of preservative-free sodium chloride for injection or preservative-free sterile water to vial. Solution made with 1 ml diluent contains 100 mcg (0.1 mg) indomethacin/0.1 ml. Solution made with 2 ml diluent contains 50 mcg (0.05 mg) indomethacin/0.1 ml. Use solution immediately because it contains no preservatives. Discard unused portion.
- Be aware that scheduled I.V. doses may be withheld if infant or neonate has anuria or a significant decrease in urine output (less than 0.6 ml/kg/hr).
- Be aware that when using I.V. form, avoid extravasation to protect surrounding tissue.
- Anticipate a second course (3 more doses) of I.V. indomethacin if patent ductus arteriosus fails to close or reopens. After 2 courses, surgery may be performed.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk. These events may occur early in treatment and risk increases with duration of use. Be aware that these events have occurred even in patients who do not have a history or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, slurring of speech, shortness of breath, or weakness. If any signs and symptoms develop, withhold indomethacin, alert prescriber immediately, and provide supportive care as prescribed.

- Monitor patient—especially if he's elderly or receiving long-term indomethacin therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, hepatic failure, and liver necrosis.
- Monitor BUN and serum creatinine levels in elderly patients, those taking ACE inhibitors or diuretics, and those with heart failure, hepatic dysfunction, or impaired renal function; drug may cause renal failure.

- Monitor CBC for decreased hemoglobin and hematocrit. Drug may worsen anemia.

**WARNING** Know that if patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of indomethacin may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because indomethacin is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Monitor weight and blood pressure, especially if patient has hypertension, because indomethacin causes sodium retention.
- Keep in mind when drug is used to treat gouty arthritis, expect its action to peak in 24 to 36 hours and significant swelling to gradually disappear over 3 to 5 days.
- Be aware that E.R. form shouldn't be used to treat gouty arthritis.
- Expect to use suppositories for patients who can't swallow oral form.
- Assess for improved joint mobility and reduced pain and inflammation to evaluate drug effectiveness.
- Expect patient to have intermittent checkups during long-term therapy and an ophthalmologic examination if vision changes.

## **PATIENT TEACHING**

- Urge patient to take indomethacin capsules with full glass of water and to avoid lying down for 15 to 30 minutes afterward. This helps prevent drug from lodging in esophagus and causing irritation. Caution patient not to crush or open capsules.
- Instruct patient to take drug with food or an antacid to reduce GI distress.
- Instruct patient to make sure suppository stays in rectum at least 1 hour.
- Urge patient to avoid alcohol during indomethacin therapy.

- Remind patient that improvement may not occur for 2 to 4 weeks after starting indomethacin to treat arthritis or ankylosing spondylitis and that he should continue taking drug, as prescribed.
- Caution against prolonged sun exposure during therapy.
- Urge patient to notify prescriber immediately about changes in hearing or vision, fever, itching, rash, sore throat, or swelling in arms or legs.
- Emphasize importance of having ordered laboratory tests and eye examinations during long-term therapy.
- Caution pregnant patient not to take NSAIDs such as indomethacin during last trimester because they may cause premature closure of the ductus arteriosus.
- Explain that indomethacin may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, edema, shortness of breath, slurring of speech, unexplained weight gain, or weakness.
- Explain that indomethacin may increase risk of serious adverse GI reactions; emphasize need to seek immediate medical attention for such signs and symptoms as abdominal or epigastric pain, indigestion, black or tarry stools, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.

**infiximab**

**Remicade**

**infiximab abda**

**infiximab axxq**

**Avsola**

**Renflexis**

**infliximab dyyb**

**Inflectra, infliximab-qbtx, Ixifi**

## **Class and Category**

*Pharmacologic class:* Monoclonal antibody (tumor necrosis factor [TNF] blocker)

*Therapeutic class:* Anti-inflammatory

## **Indications and Dosages**

- *To control moderate to severe Crohn's disease long-term; to treat active ankylosing spondylitis; to treat psoriatic arthritis with or without methotrexate; to treat moderate to severe active ulcerative colitis in patients who have had an inadequate response to conventional therapy; to treat chronic severe plaque psoriasis in patients who are candidates for systemic therapy and when other systemic therapies are medically less appropriate*

### **I.V. INFUSION**

**Adults.** *Initial:* 5 mg/kg infused over 2 hr, repeated 2 and 6 wk after first infusion. *Maintenance:* 5 mg/kg infused over 2 hr every 6 wk (active ankylosing spondylitis) or 8 wk (other indications).

***DOSAGE ADJUSTMENT*** For adults who respond to treatment for Crohn's disease and then lose response, dosage may be increased to 10 mg/kg.

- *To treat moderate to severe pediatric Crohn's disease; to treat moderate to severe pediatric active ulcerative colitis*

## **I.V. INFUSION**

**Children ages 6 and over.** 5 mg/kg infused over 2 hr, repeated 2 and 6 wk after first infusion. *Maintenance:* 5 mg/kg infused over 2 hr every 8 wk.

- *As adjunct to treat moderate to severe active rheumatoid arthritis along with methotrexate*

## **I.V. INFUSION**

**Adults.** *Initial:* 3 mg/kg infused over 2 hr, repeated 2 and 6 wk after first infusion. *Maintenance:* 3 mg/kg infused over 2 hr every 8 wk.

***DOSAGE ADJUSTMENT*** For adults who have an incomplete response, dosage increased up to 10 mg/kg per infusion or treatment frequency increased to every 4 wk.

## **Mechanism of Action**

Binds with cytokine tumor necrosis factor-alpha (TNF-alpha), preventing it from binding with its receptors. As a result, TNF-alpha can't produce proinflammatory cytokines and endothelial permeability. Infiltration of inflammatory cells into inflamed intestine and joints declines.

## **Incompatibilities**

Don't infuse infliximab in same I.V. line with other drugs or through plasticized polyvinyl chloride infusion equipment or devices.

# Contraindications

Doses greater than 5 mg/kg in patients with moderate to severe heart failure; hypersensitivity to infliximab, murine proteins, or their components

# Interactions

## DRUGS

*abatacept, anakinra, etanercept, tocilizumab*: Increased risk of neutropenia and serious infections

*CYP450 substrates such as cyclosporine, theophylline, warfarin*: May normalize formation of CYP450 enzymes which could affect dosage requirements of these drugs

*immunosuppressants*: Fewer infusion reactions in patients treated for Crohn's disease

*live vaccines, therapeutic infectious agents such as BCG in bladder instillation*: Increased risk of adverse vaccine effects

*methotrexate*: Decreased incidence of anti-infliximab antibody production and increased infliximab product concentrations

# Adverse Reactions

**CNS**: Chills, **CVA**, dizziness, fatigue, fever, headache, **meningitis**, neuritis, neuropathies, numbness, paresthesia, peripheral demyelinating disorders, **seizures**, syncope, tingling

**CV**: **Arrhythmias**, **bradycardia**, chest pain, edema, **heart failure**, hypertension, **hypotension**, **MI**, myocardial ischemia, myelitis, neuropathies, **pericardial effusion**, systemic and cutaneous vasculitis, thrombophlebitis

**EENT:** Laryngeal/pharyngeal edema, oral candidiasis, pharyngitis, rhinitis, sinusitis, transient vision loss, visual changes

**GI:** Abdominal hernia; abdominal pain; acute hepatic failure; cholecystitis; cholestasis; constipation; diarrhea; dyspepsia; elevated aminotranferases; GI hemorrhage; hepatitis, hepatotoxicity; ileus; intestinal obstruction, perforation, or stenosis; jaundice; melena; nausea; pancreatitis; splenic infarction; splenomegaly; vomiting

**GU:** Cervical cancer, kidney infection, renal failure, ureteral obstruction, UTI, vaginal candidiasis, vaginitis

**HEME:** Agranulocytosis, anemia, aplastic anemia, hemolytic anemia, leukemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia, thrombocytopenic purpura

**MS:** Ankylosing spondylitis, arthralgia, back pain, limb weakness, myalgia, psoriatic arthritis, transverse myelitis

**RESP:** Adult respiratory distress syndrome, bronchitis, bronchospasms (severe), cough, dyspnea, interstitial lung disease, pleurisy, pneumonia, pulmonary edema, tuberculosis, respiratory tract infection, severe bronchospasm, wheezing

**SKIN:** Cellulitis, diaphoresis, erythema multiforme, facial flushing, melanoma, Merkel cell cancer, pruritus, psoriasis (new or worsening), rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis; antibody formation to infliximab; bacterial (including *Legionella* and *Listeria*), fungal, mycobacterial, parasitic, or viral infections; dehydration; infusion reaction; lupus-like symptoms; lymphadenopathy; malignancies, such as lymphomas, including

hepatosplenic T-cell lymphoma; sarcoidosis; sepsis; serum sickness; vaccine breakthrough infection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but other IgG antibodies do cross the placental barrier and cases of agranulocytosis in infants exposed to drug in utero have been reported as well as an increased risk of infection that can become fatal.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Know that a six-month waiting period following birth is recommended before live vaccines should be administered to the infant.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that infliximab therapy shouldn't be started in a patient with an active infection, including serious localized infection.
- Know that because drug increases risk of developing tuberculosis or reactivating latent tuberculosis, expect prescriber to evaluate patient's risk and start tuberculosis treatment, as needed, before starting infliximab.
- Use with extreme caution if patient has a history of chronic or recurrent infection, known exposure to tuberculosis, an underlying condition that predisposes to infection, or residence or travel to areas of endemic tuberculosis or mycoses, such as blastomycosis, coccidioidomycosis, or histoplasmosis.

- Use with extreme caution in patients with heart failure because drug can worsen heart failure and increase mortality in these patients. Also know that new heart failure can develop in patients without known preexisting cardiovascular disease. Closely monitor patient throughout infliximab therapy for signs and symptoms of heart failure. If new or worsening symptoms of heart failure occur, expect drug to be discontinued.
- Use cautiously in elderly patients because they have a higher risk of infection.
- Use cautiously in patients with previous or ongoing hematologic abnormalities because infliximab may cause serious or even life-threatening adverse hematologic effects. Monitor patient's CBC regularly, as ordered. If adverse effects occur, expect drug to be discontinued.
- Be aware that use of TNF-blocking therapy, including infliximab, may reactivate hepatitis B virus in patients who are chronic carriers of this virus. Ensure that patient has been tested for hepatitis B infection before infliximab therapy is begun. For patients who develop reactivation of hepatitis B, know that therapy should be stopped and antiviral therapy with appropriate supportive treatment begun.

**WARNING** Be aware that infliximab increases risk of serious or fatal opportunistic infections, including invasive fungal infections, as well as bacterial (including *Legionella* and *Listeria*), mycobacterial, parasitic, and viral infections. The most common ones include aspergillosis, blastomycosis, candidiasis, coccidioidomycosis, cryptococcosis, histoplasmosis, legionellosis, listeriosis, pneumocytosis, salmonellosis, and tuberculosis.

**WARNING** Watch for infection, especially if patient receives immunosuppressant therapy or has a chronic infection. Upper respiratory tract infections and UTI are most common, but sepsis and fatal infections have occurred. If infection is suspected, notify prescriber, and if a serious infection is confirmed, expect drug to be discontinued.

- Reconstitute infliximab, by using a 21G (or smaller) needle to add 10 ml sterile water for injection to each vial of drug. Swirl to mix; don't shake. Solution may foam and be clear or light yellow.

- Withdraw volume equal to amount of reconstituted drug from a 250-ml glass bottle or polypropylene or polyolefin infusion bag of normal saline solution. Then add reconstituted infliximab to bottle to dilute to 250 ml. Use within 3 hours.
- Know that the infusion should be given over at least 2 hours using polyethylene-lined infusion set and in-line, sterile, nonpyrogenic, low-protein-binding filter with pores 1.2 microns or less. Don't reuse.
- Expect to premedicate patient, as prescribed, with acetaminophen, antihistamines, and/or corticosteroids to decrease an infusion reaction. If a mild to moderate infusion reaction occurs, notify prescriber and expect to slow or suspend infusion. If infusion was suspended, know that once the reaction has been resolved, the infusion may be restarted at a lower infusion rate and patient premedicated if not done before. If a severe infusion reaction occurs, know that infusion should be stopped and drug permanently discontinued. Be prepared to provide supportive emergency care according to protocol.
- Be aware that a reaction may occur 2 hours to 12 days after infusion.
- Monitor patient closely for the first 24 hours after the initial drug infusion because serious cardiovascular and cerebrovascular reactions, such as CVA, MI, seizures, or severe bronchospasms, may occur during and after infusion. Also, monitor patient for transient visual loss during or within 2 hours of infusion. If serious reactions occur, stop infusion, notify prescriber, and expect to provide supportive emergency care, as ordered.
- Monitor liver function because severe hepatic reactions may occur. Expect to stop drug if jaundice develops or liver enzymes are five times or more the upper limit of normal.
- Be aware that infliximab is a tumor necrosis factor (TNF) blocker. Malignancies, especially leukemia and such rare lymphomas as hepatosplenic T-cell lymphoma, have been reported in patients, particularly children and adolescents, receiving TNF blockers. Patients at increased risk of leukemia are those with rheumatoid arthritis. Patients at increased risk of lymphomas are those with ankylosing spondylitis, Crohn's disease, plaque psoriasis, psoriatic arthritis, and rheumatoid arthritis, especially those with long-term or very active disease. Other malignancies, such as cervical cancer and skin cancer, have also occurred. Monitor them closely.

## **PATIENT TEACHING**

- Inform patient that infliximab should take effect within 1 to 2 weeks.

- Urge patient to report evidence of infection, such as cough, painful urination, and sore throat. Infusion reaction (chest pain, chills, dyspnea, facial flushing, fever, itching, headache, rash) may occur for up to 12 days.
- Explain that infliximab increases the risk of lymphoma and other malignancies; urge prompt medical attention for suspicious signs or symptoms. Also, advise patient to have regular skin examinations because drug increases risk of skin cancer and for female patients to have periodic screening for cervical cancer.
- Advise patient not to receive vaccinations using live vaccines. Also advise parents not to have their infant exposed to live vaccines for up to 6 months after birth if the mother was taking infliximab during the pregnancy.

## insulin, inhaled

(rapid-acting)

**Afrezza**

### Class and Category

*Pharmacologic class:* Human insulin

*Therapeutic class:* Antidiabetic

### Indications and Dosages

- *To improve glycemic control in patients with diabetes mellitus*

**oral inhalation**

**Adults who are not currently taking insulin.** *Initial:* 4 units at beginning of each meal with dosage increased, as needed.

**Adults converting from subcutaneous mealtime (prandial) insulin.** Dosage dependent upon subcutaneous insulin dosage as follows: 4 units at beginning of each meal if up to 4 units of subcutaneous mealtime insulin was being used; 8 units at beginning of each meal if 5 to 8 units of subcutaneous mealtime insulin was used; 12 units at beginning of each meal if 9 to 12 units of subcutaneous mealtime insulin was used; 16 units if 13 to 16 units of subcutaneous mealtime insulin was used; 20 units at beginning of each meal if 17 to 20 units of subcutaneous mealtime insulin was used; and 24 units at beginning of each meal if 21 to 24 units of subcutaneous mealtime insulin was used. *Maintenance:* Dosage based on blood glucose monitoring results, glycemic control goal, and metabolic needs.

**Adults converting from subcutaneous premixed insulin.** Both basal and mealtime dosages required for conversion. *Mealtime dosage:* Beginning-of-mealtime injected dose estimated by dividing half of the total daily injected premixed insulin dose equally among the three meals of the day. Then each estimated injected mealtime dose converted as follows: 4 units if up to 4 units of subcutaneous premixed insulin was used; 8 units if 5 to 8 units of subcutaneous premixed insulin was used; 12 units if 9 to 12 units of subcutaneous premixed insulin was used; 16 units if 13 to 16 units of subcutaneous premixed insulin was used; 20 units if 17 to 20 units of subcutaneous premixed insulin was used; and 24 units if 21 to 24 units of subcutaneous premixed insulin was used. *Basal dosage:* The remaining half of the total daily injected premixed dose injected as a basal insulin dose. *Maintenance:* Mealtime

and basal dosages based on, blood glucose monitoring results, glycemic control goal, and metabolic needs.

**DOSAGE ADJUSTMENT** Dosage may need to be decreased if patient is taking any of the following drugs concurrently: angiotensin converting enzyme (ACE) inhibitors, angiotensin II receptor blocking agents, disopyramide, fibrates, fluoxetine, monoamine oxidase inhibitors, other antidiabetic agents, pentoxifylline, pramlintide, propoxyphene, salicylates, somatostatin analogues, or sulfonamide antibiotics. Dosage may have to be increased if patient is taking any of the following drugs concurrently: atypical antipsychotics, corticosteroids, danazol, diuretics, estrogens, glucagon, isoniazid, niacin, oral contraceptives, phenothiazines, progestogens, protease inhibitors, somatropin, sympathomimetic agents, or thyroid hormones. Dosage may have to be increased or decreased if patient is taking any of the following concurrently: alcohol, beta blockers, clonidine, lithium, or pentamidine

## **Mechanism of Action**

Lowers blood glucose levels by stimulating peripheral glucose uptake by fat and skeletal muscle, and by inhibiting hepatic glucose production. Also enhances protein synthesis, inhibits lipolysis in adipocytes, and inhibits proteolysis.

## **Contraindications**

Chronic lung disease (asthma, chronic obstructive pulmonary disease), during episodes of hypoglycemia, hypersensitivity to regular human insulin or any of its components

# Interactions

## DRUGS

*angiotensin converting enzyme (ACE) inhibitors, angiotensin II receptor blocking agents, disopyramide, fibrates, fluoxetine, monoamine oxidase inhibitors, other antidiabetic agents, pentoxifylline, pramlintide, propoxyphene, salicylates, somatostatin analogues, sulfonamide antibiotics: Increased risk of hypoglycemia atypical antipsychotics, corticosteroids, danazol, diuretics, estrogens, glucagon, isoniazid, niacin, oral contraceptives, phenothiazines, progestogens, protease inhibitors, somatropin, sympathomimetic agents, thyroid hormones: Decreased effectiveness of inhaled insulin beta blockers, clonidine, lithium, or pentamidine: Possibly decreased or increased blood glucose levels beta blockers, clonidine, guanethidine, reserpine: Blunted hypoglycemic signs and symptoms thiazolidinediones: Increased risk of fluid retention and heart failure*

## ACTIVITIES

*alcohol use: Possibly decreased or increased blood glucose levels*

## Adverse Reactions

**CNS:** Confusion, dizziness, drowsiness, fatigue, headache

**CV:** Tachycardia

**EENT:** Throat irritation or pain

**ENDO:** **Diabetic ketoacidosis, hypoglycemia**

**GI:** Diarrhea, nausea

**GU:** UTI

**RESP:** **Acute bronchospasm**, bronchitis, cough, decline in pulmonary function, dyspnea, **lung cancer** (rare), shortness of breath

**SKIN:** Diaphoresis, rash

**Other:** **Anaphylaxis**, **angioedema**, anti-insulin antibodies, **hypokalemia**, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that inhaled insulin is not a substitute for long-acting insulin and must be used in combination with long-acting insulin in patients with type 1 diabetes mellitus.
- Know that inhaled insulin should not be used to treat diabetic ketoacidosis, nor should it be used in patients who smoke or who have recently stopped smoking. Also know that drug is not recommended in patients with active lung cancer or who have a prior history of lung cancer or risk factors for lung cancer because, although rare, lung cancer has occurred in nonsmokers prescribed inhaled insulin.
- Ensure that patient has had a complete medical history, physical examination, and spirometry before inhaled insulin therapy is begun to identify potential lung disease, as the drug is contraindicated in patients with chronic lung disease. Spirometry should be repeated after the first 6 months of therapy and annually thereafter. Expect drug to be

discontinued if patient experiences a 20% or more decline in pulmonary function.

- Administer inhaled insulin using only the Afrezza inhaler. Each cartridge provides a single inhalation.

**WARNING** Monitor patient closely for signs and symptoms of hypoglycemia, which could become severe, causing seizures or even death. If present, withhold inhaled insulin, treat according to standard of care, and notify prescriber.

- Monitor patient's blood glucose level closely to detect need for dosage adjustment, as ordered. Expect dosage adjustments with changes in patient's hepatic or renal function, meal patterns, and physical activity, or during acute illness.
- Monitor patient for hypersensitivity reactions. If present, withhold drug, treat according to standard of care, and monitor patient closely until signs and symptoms resolve. Notify prescriber and expect drug to be discontinued and replaced with subcutaneous forms of insulin therapy.
- Monitor patient's serum potassium levels throughout inhaled insulin therapy in patients at risk for hypokalemia, such as those using, drugs sensitive to serum potassium concentrations, intravenously administered insulin or potassium lowering drugs.

## **PATIENT TEACHING**

- Teach patient how to use the inhaler device.
- Tell patient that doses that exceed 8 units per mealtime will require more than one cartridge.
- Instruct patient to keep the inhaler level, the white mouthpiece on the top, and the purple base on the bottom after a cartridge has been inserted into the inhaler. Remind patient that loss of drug effect can occur if the inhaler is turned upside down, held with the mouthpiece pointing down, or shaken (or dropped) after the cartridge has been inserted but before the dose has been administered. If any of these events occur, tell patient to replace the cartridge before use.

**WARNING** Review signs and symptoms of hypoglycemia and how to treat them. If frequent or severe, tell patient to

notify prescriber, as dosage may need to be adjusted.  
Stress importance of monitoring blood glucose levels.

- Stress importance of not ingesting alcoholic beverages or smoking while using inhaled insulin.
- Tell patient to avoid performing hazardous activities such as driving until the effects of inhaled insulin on her nervous system is known.

## ipratropium bromide

**Atrovent, Atrovent HFA, Kendral-Ipratropium (CAN)**

### Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Bronchodilator

### Indications and Dosages

- *To provide maintenance treatment for bronchospasm associated with chronic obstructive pulmonary disease (COPD), including chronic bronchitis and emphysema*

### INHALATION AEROSOL

**Adults.** *Initial:* 2 inhalations four times daily, increased, as needed. *Maximum:* Up to 12 inhalations/24 hr.

### INHALATION SOLUTION FOR NEBULIZER

**Adults.** 500 mcg dissolved in preservative-free sterile normal saline solution every 6 to 8 hr.

➤ *To treat perennial and allergic rhinitis*

## NASAL SPRAY

**Adults and children age 6 and over.** 2 sprays of 0.03% (21 mcg/spray) per nostril twice daily or three times daily  
*Maximum:* 12 sprays (252 mcg)/24 hr.

➤ *To treat rhinorrhea caused by seasonal allergic rhinitis*

## NASAL SPRAY

**Adults and children age 5 and over.** 2 sprays of 0.06% (42 mcg/spray) per nostril four times daily for up to 3 wk.  
*Maximum:* 16 sprays (672 mcg)/24 hr.

➤ *To treat rhinorrhea associated with the common cold*

## NASAL SPRAY

**Adults and adolescents.** 2 sprays of 0.06% (42 mcg/spray) per nostril three or four times daily for up to 4 days.

**Children ages 5 to 11.** 2 sprays of 0.06% (42 mcg/spray) per nostril three times daily for up to 4 days.

Route	Onset	Peak	Duration
Inhalation	5-15 min	1-2 hr	3-8 hr
Nasal	5 min	1-4 hr	4-8 hr

## Contraindications

Hypersensitivity to atropine, ipratropium bromide, or their components

# Interactions

## DRUGS

*anticholinergics*: Increased anticholinergic effects

## Adverse Reactions

**CNS:** Dizziness, insomnia

**CV:** **Atrial fibrillation** (oral inhalation), **bradycardia** (nasal spray), edema, hypertension, palpitations, **supraventricular tachycardia** (oral inhalation), tachycardia

**EENT:** Acute eye pain, dry mouth or pharyngeal area, increased intraocular pressure, **laryngospasm**, taste perversion, **oropharyngeal edema** (all drug forms); blurred vision, conjunctival and corneal congestion, eye irritation and pain, mydriasis, visual halos (if nasal spray comes in contact with eyes); epistaxis, mydriasis, nasal dryness and irritation, pharyngitis, rhinitis, sinusitis, tinnitus (with nasal spray)

## Mechanism of Action

After acetylcholine is released from cholinergic fibers, ipratropium prevents it from attaching to muscarinic receptors on membranes of smooth-muscle cells, as shown at right. By blocking acetylcholine's effects in bronchi and bronchioles, ipratropium relaxes smooth muscles and causes bronchodilation.

Description

**GI:** **Bowel obstruction**, constipation, diarrhea, ileus, nausea, vomiting

**GU:** Prostatitis, urine retention

**MS:** Arthritis

**RESP:** Bronchitis, **bronchospasm**, cough, dyspnea, increased sputum production, wheezing

**SKIN:** Dermatitis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms

## Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use ipratropium cautiously in patients with angle-closure glaucoma, benign prostatic hyperplasia, or bladder neck obstruction and in patients with hepatic or renal dysfunction.
- When using a nebulizer, apply a mouthpiece to prevent drug from leaking out around mask and causing blurred vision or eye pain.

**WARNING** Monitor patient for hypersensitivity reactions that could be life-threatening. If present, stop drug use immediately, notify prescriber, and provide supportive care, as needed.

## PATIENT TEACHING

- Caution patient not to use ipratropium to treat acute bronchospasm.
- Inform patient that although some people feel relief within 24 hours of drug use, maximum effect may take up to 2 weeks.
- Teach patient to use inhaler or nasal spray. Tell him to shake inhaler well at each use.
- Advise patient to keep spray out of his eyes because it may irritate them or blur his vision. If spray comes in contact with eyes, instruct patient to flush them with cool tap water for several minutes and to contact prescriber.

- Instruct patient to rinse mouth after each nebulizer or inhaler treatment to help minimize throat dryness and irritation.
- Teach patient to track canister contents by counting and recording number of doses.
- Advise patient to report decreased response to ipratropium as well as difficulty voiding, eye pain, nasal dryness, nose bleeds, palpitations, and vision changes.

## irbesartan

### Avapro

## Class and Category

*Pharmacologic class:* Angiotensin II receptor antagonist

*Therapeutic class:* Antihypertensive

## Indications and Dosages

- *To manage hypertension, alone or with other antihypertensives*

### **TABLETS**

**Adults and adolescents.** *Initial:* 150 mg once daily, and increased, as needed. *Maximum:* 300 mg daily.

***DOSAGE ADJUSTMENT*** Initial dosage reduced to 75 mg daily for patients with hyponatremia or hypovolemia from such causes as hemodialysis or vigorous diuretic therapy.

- *To treat nephropathy in type 2 diabetes mellitus in patients with hypertension, an elevated serum creatinine, and proteinuria*

## TABLETS

**Adults.** 300 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	In 4–6 wk	Unknown

## Mechanism of Action

Selectively blocks binding of the potent vasoconstrictor angiotensin (AT) II to AT<sub>1</sub> receptor sites in many tissues, including adrenal glands and vascular smooth-muscle. This inhibits the aldosterone-secreting and vasoconstrictive effects of AT II, which reduces blood pressure.

## Contraindications

Concurrent aliskiren use in patients with diabetes, hypersensitivity to irbesartan or its components

## Interactions

### DRUGS

*angiotensin converting enzyme (ACE) inhibitors, aliskiren (patients with diabetes or renal impairment), other*

*angiotensin receptor blockers:* Increased risk of hyperkalemia, hypotension, and renal dysfunction

*lithium:* Possibly increased serum lithium level

*NSAIDs:* Possible decreased renal function in patients who are elderly, volume-depleted, or have a compromised renal function

*potassium-sparing diuretics, potassium supplements, or salt substitutes containing potassium:* Possible hyperkalemia

# Adverse Reactions

**CNS:** Anxiety, dizziness, fatigue, headache, nervousness

**CV:** Chest pain, **hypotension**, peripheral edema, tachycardia

**EENT:** Pharyngitis, rhinitis, tinnitus

**GI:** Abdominal pain, diarrhea, elevated liver enzymes, heartburn, **hepatitis**, indigestion, jaundice, nausea, vomiting

**GU:** Impaired renal function, **renal failure**, UTI

**MS:** Musculoskeletal pain

**HEME:** **Thrombocytopenia**

**MS:** Increased CPK level, **rhabdomyolysis**

**RESP:** Upper respiratory tract infection

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis including shock, angioedema, hyperkalemia**

# Childbearing Considerations

## PREGNANCY

- Drug can cause fetal harm, especially if exposure occurs during the second or third trimester.
- Drug reduces fetal renal function leading to anuria and renal failure and increases fetal and neonatal morbidity and death. It can also cause fetal lung hypoplasia, hypotension, and skeletal deformations such as skull hypoplasia.
- Drug is contraindicated in pregnant women and should be discontinued as soon as possible when pregnancy is known.

## LACTATION

- It is not known if drug is present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions including hypokalemia, hypotension, and renal impairment in the breastfed infant.

## Nursing Considerations

- Know that if patient has known or suspected hypovolemia, provide treatment, such as I.V. normal saline solution, as prescribed, to correct this condition before beginning irbesartan therapy. Or expect to begin therapy with a lower dosage.
- Check blood pressure often to evaluate drug's effectiveness.
- Be aware that if blood pressure isn't controlled with irbesartan alone, expect to also give a diuretic, such as hydrochlorothiazide, as prescribed.

**WARNING** Be alert for hypotension in a patient who receives a diuretic or another antihypertensive during irbesartan therapy. Frequently monitor blood pressure. If patient experiences symptomatic hypotension, expect to stop drug temporarily. Immediately place him in supine position and prepare to give I.V. normal saline solution, as prescribed. Expect to resume drug therapy after blood pressure stabilizes.

- Be aware that if patient receives a diuretic, provide adequate hydration, as appropriate, to help prevent hypovolemia. Also monitor patient for signs and symptoms of hypovolemia, such as dizziness, fainting, and hypotension.

**WARNING** Monitor patient for increased BUN and serum creatinine levels if he has heart failure or impaired renal function because drug may cause acute renal failure. If increases are significant or persistent, notify prescriber immediately.

## PATIENT TEACHING

- Advise patient to take drug at the same time each day to maintain its therapeutic effect.
- Explain importance of regular exercise, proper diet, and other lifestyle changes in controlling hypertension.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to consult prescriber before taking any new drug.
- To reduce risk of dehydration and hypotension, advise patient to drink adequate fluids during hot weather and exercise.
- Instruct patient to contact prescriber if diarrhea, severe nausea, or vomiting, occurs and continues, because of the risk of dehydration and hypotension.

**WARNING** Advise female patient to notify prescriber immediately about known or suspected pregnancy. Explain that if she becomes pregnant, prescriber may replace irbesartan with another antihypertensive that's safe to use during pregnancy.

- Urge patient to keep follow-up appointments with prescriber to monitor progress.

## iron dextran

***(contains 50 mg of elemental iron per milliliter)***

**DexFerrum, DexIron (CAN), InFeD**

## Class and Category

*Pharmacologic class:* Iron mineral

*Therapeutic class:* Hematinic

## Indications and Dosages

- *To treat iron deficiency anemia when oral administration is impossible or unsatisfactory*

### **I.M. INJECTION I.V. INFUSION (INFED)**

**Adults and children weighing more than 15 kg (33 lb).** Calculated using following formula:  $\text{Dose (ml)} = 0.0442 (\text{desired hemoglobin} - \text{observed hemoglobin}) \times \text{lean body weight (LBW) in kg}$  (Males = 50 kg + 2.3 kg for each inch of patient's height over 5 feet. Females = 45.5 kg + 2.3 kg for each inch of patient's height over 5 feet.) +  $(0.26 \times \text{LBW})$ . Or, consult dosage table in package insert. *Test dose on day 1:* 0.5 ml by Z-track technique for I.M. injection or I.V. infusion given over at least 5 min followed in 1 hr or more with remainder of dose, if no reaction occurs. Total dosage repeated once daily thereafter. I.M. injection given by Z-track technique. I.V. infusion given over 1 ml/min with single dose not exceeding 100 mg.

**Children over age 4 months weighing 5 to 15 kg (11 to 33 lb).** Calculated using following formula:  $\text{Dose (ml)} = 0.0442 (\text{desired hemoglobin} - \text{observed hemoglobin}) \times \text{weight in kg} + (0.26 \times \text{weight in kg})$ . Or, consult dosage table in package insert. *Test dose on day 1:* 0.5 ml by Z-track technique for I.M. injection or I.V. infusion given over at least 5 min followed in 1 hr or more with remainder of dose, if no reaction occurs. Total dosage repeated once daily thereafter. I.M. injection given by Z-track technique. I.V. infusion given over 1 ml/min with single dose not exceeding 100 mg.

- *To replace iron lost in blood loss*

## **I.V. INFUSION**

**Adults.** Replacement iron (mg) = Blood loss (ml) × hematocrit. Infuse at a slow gradual rate that does not exceed 50 mg (1 ml)/min.

## **Mechanism of Action**

Restores hemoglobin and replenishes iron stores. Iron, an essential component of hemoglobin, myoglobin, and several enzymes (including catalase, cytochromes, and peroxidase), is needed for catecholamine metabolism and normal neutrophil function.

In iron dextran therapy, iron binds to available protein parts after the drug has been split into dextran and iron by cells of the reticuloendothelial system. The bound iron forms hemosiderin or ferritin, physiologic forms of iron, and transferrin, which replenish hemoglobin and deplete iron stores. Dextran is metabolized or excreted.

## **Incompatibilities**

Don't mix iron dextran with blood for transfusion, other drugs, or parenteral nutrition solutions for I.V. infusion.

## **Contraindications**

Anemia other than iron deficiency, hypersensitivity to iron dextran or its components

## **Interactions**

### **DRUGS**

None reported

# Adverse Reactions

**CNS:** Chills, disorientation, dizziness, fever, headache, malaise, paresthesia, **seizures**, syncope, unconsciousness, weakness

**CV:** **Arrhythmias**, **bradycardia**, chest pain, hypertension, **hypotension**, **shock**, tachycardia

**EENT:** Altered taste

**GI:** Abdominal pain, diarrhea, nausea, vomiting

**GU:** Hematuria

**HEME:** Leukocytosis

**MS:** Arthralgia, arthritis, backache, myalgia, **rhabdomyolysis**

**RESP:** **Bronchospasm**, **cyanosis**, dyspnea, **respiratory arrest**, wheezing

**SKIN:** **Diaphoresis**, rash, pruritus, purpura, urticaria

**Other:** **Anaphylaxis**, infusion-site phlebitis

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that iron dextran is given only when oral therapy isn't feasible.
- Expect to monitor hematocrit, hemoglobin level, serum ferritin level, and transferrin saturation, as ordered, before, during, and after iron dextran therapy.

**WARNING** Expect with first dose to administer a test dose as prescribed, and monitor patient closely for anaphylactic reaction. Expect to wait 1 or more hours before giving remainder of dose if no reaction occurs.

- Infuse undiluted iron dextran slowly, at no more than 1 ml/minute (50 mg/minute).
- Change needle after drawing up iron dextran into syringe if giving by intramuscular injection. Administer intramuscular injection using Z-track method. Inject deep into the upper outer quadrant of the patient's buttock. Do not inject drug into any other site. Use a 2- to 3-inch, 19G or 20G needle.

**WARNING** Monitor patient closely for signs and symptoms of anaphylaxis (such as collapse, dyspnea, loss of consciousness, seizures, and severe hypotension) during and after drug administration. Patients with a history of allergies or asthma are at increased risk for anaphylaxis, possibly death. Institute emergency resuscitation measures as needed, including epinephrine administration, as prescribed.

**WARNING** Assess blood pressure often after iron dextran administration, especially if given intravenously, because hypotension is a common adverse effect that may be related to infusion rate; avoid rapid infusion.

- Be aware that patient may have adverse reactions, including arthralgia, backache, chills, and vomiting, 1 to 2 days after drug therapy. Symptoms should resolve within 3 to 4 days.
- Assess patients with a history of rheumatoid arthritis for exacerbation of joint pain and swelling.

- Know that if patient has cardiovascular disease, watch for worsening from drug's adverse effects.
- Assess patient for iron overload, characterized by bleeding in GI tract and lungs, decreased activity, pale eyes, and sedation.
- Store iron dextran at 15° to 30° C (59° to 86° F).

## PATIENT TEACHING

- Instruct patient to report immediately signs of adverse reaction, such as rash, shortness of breath, or wheezing, during iron dextran therapy.
- Advise patient not to take any oral iron without first consulting prescriber.
- Urge patient to plan periods of activity and rest to avoid excessive fatigue.
- Emphasize need to follow dosage regimen and keep follow-up medical and laboratory appointments.

## iron sucrose

***(contains 100 mg of elemental iron per 5 ml)***

**Venofer**

## Class and Category

*Pharmacologic class:* Iron mineral

*Therapeutic class:* Hematinic

## Indications and Dosages

- *To treat iron deficiency anemia in patients with hemodialysis dependent-chronic kidney disease*

## **I.V. INJECTION, I.V. INFUSION**

**Adults.** *Initial:* 100 mg elemental iron injected undiluted over 2 to 5 min during dialysis. Alternatively, 100 mg elemental iron infused diluted over at least 15 min during dialysis. *Usual:* 100 mg elemental iron every wk to 3 times/wk to total dose of 1,000 mg. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 100 mg/dose.

- *To treat iron-deficiency anemia patients with peritoneal dialysis dependent-chronic kidney disease*

## **I.V. INFUSION**

**Adults.** *Initial:* 300 mg elemental iron infused diluted over 1.5 hr on days 1 and 14, followed by 400 mg elemental iron infused over 2.5 hr on day 28. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 1,000 mg/28 days.

- *To maintain iron therapy in children with chronic kidney disease who are nondialysis-dependent receiving erythropoietin or who are peritoneal-dialysis-dependent receiving erythropoietin; to maintain iron therapy in children with hemodialysis dependent-chronic kidney disease (HDD-CKD)*

## **I.V. INJECTION, I.V. INFUSION**

**Children age 2 years and over.** 0.5 mg/kg, not to exceed 100 mg/dose, every 2 wk (HDD-CKD) or 4 wk (other indications) for 12 wk given undiluted over 5 min as an I.V.

injection or diluted and infused over 5 to 60 min as an I.V. infusion. Treatment repeated, as needed.

- *To treat iron deficiency anemia in nondialysis patients with chronic renal disease.*

## **I.V. INJECTION, I.V. INFUSION**

**Adults.** *Initial:* 200 mg elemental iron injected undiluted over 2 to 5 min and repeated 4 more times over a 14-day period for a total dose of 1,000 mg. Alternatively, 200 mg elemental iron infused diluted over at least 15 min or 500 mg elemental iron infused diluted over 3.5 to 4 hr on day 1 and day 14. Dosage repeated as needed to maintain target levels of hemoglobin and hematocrit and acceptable blood iron level. *Maximum:* 1,000 mg/14 days.

## **Mechanism of Action**

Acts to replenish iron stores lost during dialysis because of increased erythropoiesis and insufficient absorption of iron from GI tract. Iron is an essential component of hemoglobin, myoglobin, and several enzymes, including catalase, cytochromes, and peroxidase, and is needed for catecholamine metabolism and normal neutrophil function. Iron sucrose injection also normalizes RBC production by binding with hemoglobin or being stored as ferritin in reticuloendothelial cells of the bone marrow, liver, or spleen.

## **Incompatibilities**

Don't mix with other drugs or parenteral nutrition solutions for I.V. infusion.

## **Contraindications**

Anemia other than iron deficiency, hypersensitivity to iron components, iron overload

## Interactions

### DRUGS

*oral iron preparations:* Possibly reduced absorption of oral iron supplements

## Adverse Reactions

**CNS:** Asthenia, **collapse**, confusion, dizziness, fatigue, fever, headache, hypoesthesia, light-headedness, loss of consciousness, malaise, **seizures**

**CV:** **Bradycardia**, chest pain, edema, **heart failure**, hypertension, **hypotension**, peripheral edema, **shock**

**EENT:** Conjunctivitis, ear pain, nasal congestion, nasopharyngitis, rhinitis, sinusitis, taste perversion

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, constipation, diarrhea, elevated liver enzymes, nausea, occult-positive feces, peritoneal infection, vomiting

**GU:** Chromaturia, UTI

**MS:** Arthralgia, arthritis, back pain, joint swelling, leg cramps, muscle pain or weakness, myalgia

**RESP:** **Bronchospasm**, cough, dyspnea, pneumonia, upper respiratory tract infection

**SKIN:** Hyperhidrosis, pruritus, rash

**Other:** **Anaphylaxis**; **angioedema**; **iron overload**; gout; infusion or injection-site burning, pain, redness, or skin discoloration (with extravasation); **sepsis**

## Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for gastrointestinal toxicity (constipation, diarrhea).

## Nursing Considerations

- Reconstitute iron sucrose injection for infusion, by diluting 100 mg elemental iron in maximum of 100 ml normal saline solution (for hemodialysis patients) or 250 ml (for nondialysis and peritoneal dialysis patients) immediately before infusion. Discard any unused diluted solution.
- Give drug directly into dialysis line by slow I.V. injection or by infusion.

**WARNING** Monitor patient closely for evidence of anaphylaxis, such as collapse, dyspnea, loss of consciousness, seizures, or severe hypotension during and for at least 30 minutes after therapy. Institute emergency resuscitation measures as needed.

**WARNING** Assess blood pressure often after drug administration because hypotension is a common adverse reaction that may be related to infusion rate (avoid rapid infusion) or total cumulative dose.

- Expect to monitor hematocrit, hemoglobin, serum ferritin, and transferrin saturation, as ordered, before, during, and after iron sucrose therapy. Test serum iron level 48 hours after last dose, as ordered. Notify

prescriber and expect to stop therapy if blood iron levels are normal or elevated, to prevent iron toxicity.

- Watch for evidence of iron overload, such as bleeding in GI tract and lungs, decreased activity, pale eyes, and sedation.

## PATIENT TEACHING

- Tell patient to inform prescriber if she has a prior history of reactions to parenteral iron products before drug is given.
- Inform patient that symptoms of iron deficiency may include decreased stamina, fatigue, learning problems, and shortness of breath.
- Instruct patient to report any of the following signs and symptoms of an allergic reaction that may develop during and following the infusion of iron sucrose: breathing problems, dizziness, itching, light-headedness, rash, and swelling.
- Tell mothers who are breastfeeding while receiving iron sucrose to monitor their infant for constipation or diarrhea. If present, pediatrician should be notified, as this may indicate gastrointestinal toxicity.

## isoniazid

(isonicotinic acid hydrazide, INH)

**Isotamine (CAN)**

## Class and Category

*Pharmacologic class:* Isonicotinic acid derivatives

*Therapeutic class:* **Antitubercular agent**

## Indications and Dosages

➤ *To prevent tuberculosis*

## **ORAL SOLUTION, SYRUP, TABLETS**

**Adults over 30 kg (66 lb).** 300 mg daily for 6 to 12 mo.

**Infants and children.** 10 mg/kg daily (up to 300 mg) for up to 1 yr. Alternatively when daily compliance is uncertain, 20 to 30 mg/kg (not to exceed 900 mg) twice weekly under direct observation of a health care worker.

➤ *As adjunct to treat active tuberculosis*

## **ORAL SOLUTION, SYRUP, TABLETS I.M. INJECTION**

**Adults.** 5 mg/kg up to 300 mg once daily or 15 mg/kg (up to 900 mg) 2 or 3 times/wk.

**Infants and children.** 10 to 15 mg/kg (up to 300 mg) once daily or 20 to 40 mg/kg (up to 900 mg) 2 or 3 times/wk.

## **Mechanism of Action**

Interferes with lipid and nucleic acid synthesis in actively growing tubercule bacilli cells. Isoniazid also disrupts bacterial cell wall synthesis and may interfere with mycolic acid synthesis in mycobacterial cells.

## **Contraindications**

History of severe adverse reactions (acute liver disease of any etiology, including drug-induced hepatitis, arthritis, chills, drug fever); hypersensitivity to isoniazid or its components

## **Interactions**

## **DRUGS**

*acetaminophen*: Increased risk of hepatotoxicity  
*carbamazepine*: Increased blood carbamazepine level and toxicity  
*hepatotoxic drugs, rifampin*: Increased risk of hepatotoxicity  
*ketoconazole*: Possibly decreased blood ketoconazole level and resistance to antifungal treatment  
*phenytoin*: Increased blood phenytoin level, increased risk of phenytoin toxicity  
*theophylline, valproate*: Increased levels of these drugs

## **FOODS**

*all food*: Decreased absorption of isoniazid  
*histamine-containing foods, such as tuna, skipjack, and other tropical fish*: Inhibited action of the enzyme diamine oxidase in foods, possibly resulting in flushing, headache, hypotension, palpitations and sweating.  
*tyramine-containing foods, such as cheese and fish*: Increased response to tyramine in foods, possibly resulting in chills; diaphoresis; headache; light-headedness; and red, itchy, clammy skin

## **ACTIVITIES**

*alcohol use*: Increased risk of hepatotoxicity

## **Adverse Reactions**

**CNS**: Clumsiness, confusion, dizziness, **encephalopathy**, fatigue, fever, hallucinations, **neurotoxicity**, paresthesia, peripheral neuritis, psychosis, **seizures**, weakness

**CV**: Vasculitis

**EENT**: Optic neuritis

**ENDO**: Gynecomastia, hyperglycemia

**GI:** Abdominal pain, anorexia, elevated liver enzymes, epigastric distress, **hepatitis**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Glycosuria

**HEME:** **Agranulocytosis**, **aplastic anemia**, eosinophilia, **hemolytic anemia**, sideroblastic anemia, **thrombocytopenia**

**MS:** Arthralgia, joint stiffness

**SKIN:** **Pruritus**, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, **hypocalcemia**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, hypophosphatemia, injection-site irritation, lupus-like symptoms, lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- Drug may be used to treat active tuberculosis in pregnant women.
- Drug should be deferred to treat latent tuberculosis until after delivery to avoid risk to fetus.
- Be aware that risk of fatal maternal isoniazid-associated hepatitis may be increased, especially during the postpartum period.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding may take place during drug therapy.

## Nursing Considerations

- Administer isoniazid cautiously to alcoholic, diabetic, or malnourished patients and those at risk for peripheral neuritis.

- Give oral drug 1 hour before or 2 hours after meals to promote absorption. If GI distress occurs, give drug with a small amount of food or an antacid that doesn't contain aluminum 1 hour before or 2 hours after meal.
- Monitor liver enzyme studies, which may be ordered monthly, because isoniazid can cause severe (possibly fatal) hepatitis.
- Know that about 50% of patients metabolize isoniazid slowly, which may lead to increased toxic effects. Watch for adverse reactions, such as peripheral neuritis; if they occur, expect to decrease dosage.
- Give isoniazid with other antituberculous drugs, as prescribed, to prevent development of resistant organisms.
- Be aware that patients with advanced HIV infection may experience more severe adverse reactions in greater numbers.

## **PATIENT TEACHING**

- Instruct patient to take isoniazid exactly as prescribed and not to stop without first consulting prescriber. Explain that treatment may take months or years.
- Direct patient to take drug on an empty stomach 1 hour before or 2 hours after meals. If GI distress occurs, instruct him to take drug with food or an antacid that doesn't contain aluminum.
- Advise patient to report signs of hepatic dysfunction, including dark urine, decreased appetite, fatigue, and jaundice.
- Caution patient not to drink alcohol while taking isoniazid because alcohol increases the risk of hepatotoxicity.
- Give patient a list of tyramine-containing foods to avoid when taking isoniazid, such as cheese, fish, red wine, salami, and yeast extracts. Explain that consuming these foods during isoniazid therapy may cause unpleasant adverse reactions, such as chills, pounding heartbeat, and sweating.
- Tell patient to avoid histamine-containing foods such as tuna, skipjack, and other tropical fish during therapy to avoid such adverse reactions as flushing, headache, low blood pressure, rapid heartbeat and sweating.
- Tell patient that he'll need periodic laboratory tests and physical examinations.

- Urge patient to report fever, nausea, numbness and tingling in arms and legs, rash, vision changes, vomiting, and yellowing skin.

## isosorbide dinitrate

**Dilatrate-SR, ISDM (CAN), Isordil, Isordil Titrados**

## isosorbide mononitrate

**Apo-ISMN (CAN), Monoket**

### Class and Category

*Pharmacologic class:* Nitrate

*Therapeutic class:* Antianginal

### Indications and Dosages

➤ *To prevent angina*

#### **S.R. CAPSULES**

**Adults.** *Initial:* 40 mg (dinitrate), increased as needed with nitrate free greater than 18 hr interval daily. *Maximum:* 160 mg daily.

#### **E.R. TABLETS**

**Adults.** *Initial:* 30 to 60 mg (mononitrate) once daily in the morning, increased after several days to 120 once daily and

then after several more days to 240 mg once daily, as needed.

## S.L. TABLETS

**Adults.** 2.5 to 5 mg (dinitrate) as needed about 15 min before any activity that could cause an anginal attack.

## TABLETS

**Adults.** *Initial:* 5 to 20 mg (dinitrate) two or three times daily with nitrate free 14 hr interval daily. *Maintenance:* 10 to 40 mg two or three times daily with nitrate free 14 hr interval daily.

➤ *To prevent or treat angina pectoris*

## TABLETS

**Adults.** *Initial:* 5 to 20 mg (mononitrate) twice daily given 7 hr apart.

➤ *To treat acute angina attack in patients who fail to respond to sublingual nitroglycerin*

## S.L. TABLETS

**Adults.** 2.5 to 5 mg, repeated every 5 to 10 min, as needed, for no more than 3 doses in a 15 to 30 min period.

Route	Onset	Peak	Duration
P.O.*	1 hr <sup>†</sup>	Unknown	5–6 hr
P.O. (E.R.)*	30 min	Unknown	6–8 hr
P.O. (S.L.)*	In 3 min	Unknown	2 hr

\* For dinitrate.

† For mononitrate, onset also is 1 hr; peak and duration are unknown.

## Mechanism of Action

Isosorbide may interact with nitrate receptors in vascular smooth-muscle cell membranes. By interacting with receptors' sulfhydryl groups, drug is reduced to nitric oxide. Nitric oxide activates the enzyme guanylate cyclase, increasing intracellular formation of cyclic guanosine monophosphate (cGMP). An increased cGMP level may relax vascular smooth muscle by forcing calcium out of muscle cells, causing vasodilation. This improves cardiac output by reducing mainly preload but also afterload.

Description

---

## Contraindications

Concurrent use of phosphodiesterase inhibitors (sildenafil, tadalafil, vardenafil) or riociguat; hypersensitivity to isosorbide, other nitrates, or their components

## Interactions

### DRUGS

*phosphodiesterase inhibitors such as sildenafil, tadalafil, vardenafil:* Increased risk of hypotension, myocardial ischemia, syncope, and possibly death  
*riociguat:* Increased risk of hypotension  
*vasodilators:* Additive effects

### ACTIVITIES

*alcohol use:* Increased risk of orthostatic hypotension

## Adverse Reactions

**CNS:** Agitation, confusion, dizziness, headache, insomnia, restlessness, syncope, vertigo, weakness

**CV:** **Arrhythmias**, orthostatic hypotension, palpitations, peripheral edema, tachycardia

**EENT:** Blurred vision, diplopia (all forms); sublingual burning (S.L. form)

**GI:** Abdominal pain, diarrhea, indigestion, nausea, vomiting

**GU:** Dysuria, impotence, urinary frequency

**HEME:** **Hemolytic anemia**

**MS:** Arthralgia, muscle twitching

**RESP:** Bronchitis, pneumonia, upper respiratory tract infection

**SKIN:** Diaphoresis, flushing, rash

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use isosorbide cautiously in patients with hypovolemia or mild hypotension. Monitor patient for increased hypotension and reduced cardiac output.
- Give drug 1 hour before or 2 hours after meals. Give with meals if patient experiences adverse GI reactions or severe headaches.
- Know that patient may experience daily headaches from isosorbide's vasodilating effects. Give acetaminophen, as prescribed, to relieve pain.

**WARNING** Be aware that stopping drug abruptly may cause angina and increase the risk of MI.

- Monitor blood pressure often during isosorbide therapy, especially in elderly patients; drug may cause severe hypotension.
- Keep isosorbide protected from heat and light.

### PATIENT TEACHING

- Teach patient and family to recognize signs and symptoms of angina, including chest pain, fullness, or pressure, which commonly is accompanied by nausea and sweating. Pain may radiate down the left arm or into the neck or jaw. Inform female patients and those with diabetes mellitus or hypertension that they may experience only fatigue and shortness of breath.
- Caution patient not to crush or chew isosorbide E.R. capsules or tablets or S.L. tablets unless specifically ordered to do so by prescriber.
- Instruct patient to place S.L. tablet under tongue and not to swallow it, but to let it dissolve. Explain that moisture in mouth promotes drug absorption and that burning or tingling in the mouth indicates drug effectiveness.
- Advise patient to carry S.L. isosorbide with him at all times, if prescribed.
- Caution patient that abrupt drug discontinuation may cause angina and increase the risk of MI.
- Instruct patient to notify prescriber about blurred vision, fainting, increased angina attacks, rash, and severe or persistent headaches.
- Teach patient to reduce the effects of orthostatic hypotension by changing position slowly. Advise him to lie down if he becomes dizzy.
- Inform patient that drug commonly causes headache, which typically resolves after a few days of continuous therapy. Suggest that patient take acetaminophen as needed and as prescribed.
- Advise patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol consumption.
- Instruct patient to store drug in a tightly closed container and protect from heat and light.
- Advise male patient with erectile dysfunction to alert prescriber that he is taking isosorbide because sildenafil, tadalafil, and vardenafil can cause fatal reactions when taken with isosorbide.

## isotretinoin

# Absorica, Absorica LD, Amnesteem, Claravis, Myorisan, Zenatane

## Class and Category

*Pharmacologic class:* Retinoid

*Therapeutic class:* Acne inhibitor

## Indications and Dosages

- *To treat severe recalcitrant nodular acne unresponsive to conventional therapy*

### **CAPSULES (AMNESTEEM, CLARAVIS, MYORISAN, ZENATANE)**

**Adults.** *Initial:* 0.5 mg to 1 mg/kg daily with meals in 2 divided doses, increased as needed up to 2 mg/kg daily given in 2 divided doses. *Maximum:* 2 mg/kg daily. Course of therapy given for 15 to 20 wk with second course given, as needed, after a period of 2 mo or more off therapy.

**Children age 12 and over.** 0.5 mg to 1 mg daily with meals in 2 divided doses for 15 to 20 wk.

### **CAPSULES (ABSORICA)**

**Adults and children age 12 and over.** 0.5 to 1 mg/kg daily with or without meals in 2 divided doses for 15 to 20 wk. Second course of therapy given, as needed, after a period of 2 months or more off therapy.

### **CAPSULES (ABSORICA LD)**

**Adults and children age 12 and over.** 0.4 to 0.8 mg/kg daily with or without meals in 2 divided doses for 15 to 20 wk. Second course of therapy may be given, as needed, after a period of 2 months or more off therapy.

## Mechanism of Action

Inhibits sebaceous gland function and keratinization, which results in diminished nodular formation associated with recalcitrant nodular acne.

## Contraindications

Hypersensitivity to isotretinoin parabens, vitamin A, or any of their components, pregnancy

## Interactions

### DRUGS

*corticosteroids (systemic):* Possibly increased risk of osteoporosis

*hormonal contraceptives including levonorgestrel implants, medroxyprogesterone injection, microdosed progesterone preparations:* Possibly decreased effectiveness of contraceptive

*phenytoin:* Possibly increased risk of osteomalacia

*tetracyclines:* Increased risk of benign intracranial hypertension

*vitamin A supplements:* Increased risk of additive toxic effects

## Adverse Reactions

**CNS:** Aggressive or violent behavior, anger, anxiety, **violent behavior**, **CVA**, depression, dizziness, drowsiness, emotional instability, euphoria, fatigue, hallucinations, headache, insomnia, irritability, lethargy, malaise, nervousness, panic attack, paresthesias, **pseudotumor cerebri**, psychosis, **seizures**, **suicidal ideation**, syncope, weakness

**CV:** Chest pain, decreased high-density lipoprotein level, edema, elevated creatinine phosphokinase level, hypercholesteremia, hypertriglyceridemia, palpitation, tachycardia, **vascular thrombotic disease**, vasculitis

**ENDO:** Abnormal menses, hyperglycemia, **hypoglycemia**

**EENT:** Bleeding and inflammation of gums, blurred vision, cataracts, color vision disorder, conjunctivitis, corneal opacities, decreased night vision, dry eyes, dry mouth or nose, epistaxis, eye irritation or pruritus, eye strain, eyelid inflammation, hearing impairment, keratitis, nasal dryness, nasopharyngitis, optic neuritis, photophobia, reduced visual acuity, sty, tinnitus, visual disturbances, voice alteration

**GI:** Colitis, **hepatitis**, ileitis, inflammatory bowel disease, elevated liver enzymes, nausea, **pancreatitis**

**GU:** Abnormal menses, decreased libido, erectile dysfunction, glomerulonephritis, hematuria, proteinuria, sexual dysfunction, WBCs in urine

**HEME:** Anemia, **agranulocytosis**, **elevated platelet count**, **leukopenia**, **neutropenia**, sedimentation rate elevation, **thrombocytopenia**, thrombocytosis

**MS:** Arthralgia, arthritis, back or musculoskeletal pain, bone abnormalities, calcification of ligaments and tendons, musculoskeletal stiffness, myalgia, premature epiphyseal closure, **rhabdomyolysis**, skeletal hyperostosis, tendonitis

**RESP:** **Bronchospasms**, respiratory infection

**SKIN:** Alopecia, bruising, contact dermatitis, diaphoresis, disseminated herpes simplex, dry lips or skin, eczema, eruptive xanthomas, **erythema multiforme**, facial

erythema, flushing, fulminant acne, hair abnormalities, hirsutism, hyperpigmentation, hypopigmentation, increased sunburn susceptibility, infections, nail dystrophy, paronychia, peeling of palms and soles, photoallergic or photosensitizing reactions, pruritus, pyogenic granuloma, rash, seborrhea, skin fragility, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria  
**Other:** Abnormal wound healing, alkaline phosphatase increase, **disseminated herpes simplex, hypersensitivity reactions (may become severe)**, hyperuricemia, lymphadenopathy, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug causes fetal harm, especially severe fetal defects.
- It is contraindicated in pregnant women and women of childbearing age who are not using reliable contraception during drug therapy and for at least 1 month following drug discontinuation.
- Women of child bearing age must meet all of the following conditions before drug can be prescribed:
  1. Patient agrees to participate in the “iPLEDGE” program.
  2. Patient understands that no more than a 30-day supply of the drug will be given at any one time.
  3. Patient agrees to talk about effective birth control methods with health care provider and agrees to use 2 separate methods of effective birth control at the same time 1 month before, while taking the drug, and for 1 month after drug is discontinued.
  4. Patient has a negative monthly pregnancy test before prescription is refilled.
  5. Patient agrees to have a pregnancy test done 30 days after drug is discontinued.
- Patient understands drug may interfere with the contraceptive effect of microdosed progestin preparations and knows that microdosed “minipill”

is not recommended for use with the drug.

- Patient expresses an understanding that it is not known if there is an interaction between the drug and combined oral contraceptives.
- Patient agrees not to use St. John's Wort during drug therapy because it may make hormonal birth control pills be less effective.
- Patient agrees not to donate blood during and for at least 1 month following the completion of therapy because women of childbearing potential must not receive blood from patients being treated with drug.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions.

## Nursing Considerations

- Ensure that women of childbearing age have met the iPLEDGE restricted program requirements before drug therapy begins.

**WARNING** Notify prescriber if elevated serum triglyceride levels can't be controlled or if symptoms of pancreatitis occur (abdominal pain, nausea, vomiting). Drug may need to be discontinued because fatal hemorrhagic pancreatitis has occurred with drug use.

- Obtain serum lipid level before therapy and periodically thereafter, as ordered, to detect elevated lipid levels that result from isotretinoin therapy.
- Monitor liver enzyme levels periodically, as ordered, because drug can cause hepatitis.
- Assess patient frequently for adverse reactions and report to prescriber any that occur; drug may have serious adverse effects that require discontinuation.

## PATIENT TEACHING

- Inform patient that drug is available only through a restricted program. Review criteria and question patient regarding understanding and willingness to comply.
- Alert patient that Absorica brand of isotretinoin contains the color additive FD&C Yellow No. 5 (tartrazine), which may cause allergic reactions, especially in patients with an allergy to aspirin or who have asthma. Tell patient that if an allergic reaction occurs, regardless of brand taken, to seek immediate medical attention, if severe, and to stop taking isotretinoin.
- Instruct patient to take isotretinoin with food or milk except for Absorica or Absorica LD brands which may be taken with or without food.
- Advise women of childbearing age that two forms of contraceptives must be used simultaneously (unless absolute abstinence is the chosen method) 1 month before therapy and for 1 month after therapy has stopped because of potential for fetal harm. Inform women who use oral contraceptives that drug may lessen effectiveness of oral contraceptives. Urge patient to notify prescriber immediately if pregnancy occurs.
- Urge patient to report headache, nausea, vomiting and visual disturbances immediately to prescriber because drug will need to be discontinued immediately and patient referred to a neurologist.
- Caution patient and family that isotretinoin may cause aggressive or violent behavior, depression, psychosis, and suicidal ideation. Instruct patient to notify prescriber immediately if changes in mood occur.
- Tell patient to report, hearing changes or tinnitus; painful or trouble swallowing; rectal bleeding; severe abdominal, bowel, or chest pain; severe diarrhea or skin reactions to prescriber because drug may have to be discontinued.
- Advise patient to avoid hazardous activities until drug's CNS effects are known. Caution that changes in night vision may occur suddenly.
- Caution patient not to donate blood during therapy and for 1 month after therapy has stopped because blood might be given to a pregnant woman.
- Warn patient that transient exacerbation of acne may occur, especially during initial therapy and to notify prescriber if this occurs.
- Instruct patient to avoid wax epilation and skin resurfacing procedures during therapy and for at least 6 months thereafter because of scarring potential.
- Caution patient to avoid exposure to direct sunlight or UV light and to wear sunscreen when outdoors.

- Inform patient that contact lens tolerance may decrease during and after isotretinoin therapy and night vision may decrease as well.
- Alert patient to the potential for mild musculoskeletal adverse reactions, which usually clear rapidly after drug is discontinued. Urge patient to notify prescriber if symptoms become bothersome or serious because drug may need to be discontinued. Inform adolescents and their families that participation in sports with repetitive impact may increase their risk of hip growth plate injuries or spondylolisthesis.
- Advise patient not to take vitamin A supplements while on isotretinoin therapy because of potentially additive toxic effects. Also advise female patients of childbearing age not to self-treat depression with the herbal, St. John's wort, because it may interfere with hormonal contraceptives being used.
- Instruct patient to notify all prescribers of isotretinoin use because of the risk of interactions.
- Inform patient of need for frequent laboratory tests and importance of complying with scheduled appointments.

# isradipine

## DynaCirc

### Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antihypertensive

### Indications and Dosages

➤ *To manage essential hypertension*

### CAPSULES

**Adults.** *Initial:* 2.5 mg twice daily, increased by 5 mg every 2 to 4 wk, as needed. *Maximum:* 20 mg daily.

Route	Onset	Peak	Duration
P.O.	2-3 hr	2-4 wk	Unknown

## Mechanism of Action

Inhibits calcium movement into coronary vascular smooth-muscle cells by blocking the slow calcium channels in their membranes. By decreasing intracellular calcium level, isradipine inhibits smooth-muscle cell contractions. The result is decreased peripheral vascular resistance, reduced diastolic and systolic blood pressure, and relaxation of coronary and vascular smooth muscle, all of which decrease myocardial oxygen demand.

## Contraindications

Hypersensitivity to isradipine or its components

## Interactions

### DRUGS

*cimetidine:* Increased blood level and bioavailability of isradipine

*fentanyl anesthesia:* Increased risk of severe hypotension

*rifampicin:* Decreased isradipine concentration and effectiveness

## Adverse Reactions

**CNS:** Asthenia, **CVA**, dizziness, fatigue, headache, paresthesia, somnolence, syncope, transient ischemic

attack, weakness

**CV:** Angina, **atrial fibrillation**, **heart failure**, **hypotension**, **MI**, orthostatic hypotension, palpitations, peripheral edema, tachycardia, **ventricular fibrillation**

**EENT:** Gingival hyperplasia, pharyngitis, rhinitis

**GI:** Abdominal cramps, constipation, diarrhea, elevated liver enzymes, indigestion, nausea, vomiting

**HEME:** **Leukopenia**

**MS:** Back pain

**RESP:** Cough

**SKIN:** Flushing, photosensitivity, rash, urticaria

**Other:** **Angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Monitor blood pressure and heart rate often during isradipine therapy.
- Monitor patient with impaired hepatic or renal function for an increased blood isradipine level.
- Avoid giving isradipine with food because doing so increases time to peak effect by about 1 hour.

- Observe for mild peripheral edema caused by vasodilation of small blood vessels. Know that this type of edema doesn't result from fluid retention or heart failure.

## PATIENT TEACHING

- Inform patient that isradipine therapy will be long-term and will require laboratory tests and follow-up visits to monitor drug effects.
- Instruct patient to take drug exactly as prescribed and to swallow capsules whole, not chewing or crushing them.
- Instruct patient to take a missed dose as soon as he remembers it unless it's nearly time for the next dose. In that case, advise him to wait and take next scheduled dose, but not to double the dose. If more than one dose is missed, tell him to contact prescriber.

**WARNING** Urge patient not to stop taking drug suddenly.  
Doing so may lead to life-threatening problems.

- Inform patient that fragments of capsules may be visible in stool.
- Caution patient not to drink grapefruit juice during isradipine therapy.
- Urge patient to avoid potentially hazardous activities until isradipine's CNS effects are known.
- Caution patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to contact prescriber if he experiences chest pain, fainting, irregular heartbeat, rash, or swollen ankles while taking isradipine.
- Instruct patient to maintain good oral hygiene, perform gum massage, and see a dentist every 6 months to prevent gum bleeding and gum disorders.
- Caution patient to avoid direct sunlight and to wear protective clothing and apply sunscreen when outdoors.
- Instruct patient to store drug at room temperature in a dry place.

**istradefylline**

# Nourianz

## Class and Category

*Pharmacologic class:* Adenosine A<sub>2A</sub> receptor antagonist

*Therapeutic class:* Anti-Parkinson agent, central nervous system agent

## Indications and Dosages

- *As adjunct to treat patients with Parkinson's disease on levodopa/carbidopa experiencing "off" episodes*

### **TABLETS**

**Adults.** 20 mg once daily, increased to 40 mg if needed.

*Maximum:* 40 mg once daily.

***DOSAGE ADJUSTMENT*** For patients taking strong CYP3A4 inhibitors or patients with moderate hepatic impairment, maximum dosage should not exceed 20 mg once daily. For patients who smoke 20 or more cigarettes per day (or use the equivalent of another tobacco product), dosage is initiated and maintained at 40 mg once daily.

## Mechanism of Action

The precise mechanism in which a therapeutic effect is exerted in Parkinson disease is unknown, although it is thought to be related to its adenosine A<sub>2A</sub> receptor antagonist action.

## Contraindications

Hypersensitivity to istradefylline or its components

## Interactions

### DRUGS

*drugs to treat Parkinson's disease:* May cause impulse control issues

*strong CYP3A4 inducers such as carbamazepine, phenytoin, rifampin, St. John's wort:* Decreased istradefylline levels and effectiveness

*strong CYP3A4 inhibitors such as clarithromycin, itraconazole, ketoconazole:* Increased istradefylline levels with increased risk of adverse reactions

*CYP3A4 substrates such as atorvastatin, P-gp substrates such as digoxin:* Increased CYP3A4 substrate level with increased risk of adverse reactions

### ACTIVITIES

*smoking 20 cigarettes a day or more (or equivalent use of another tobacco product):* Decreased effectiveness of istradefylline

## Adverse Reactions

**CNS:** Dizziness, dyskinesia, hallucination, insomnia

**ENDO:** Hyperglycemia

**GI:** Constipation, decreased appetite, diarrhea, nausea

**GU:** Elevated blood urea, increased libido

**RESP:** Upper respiratory tract inflammation

**SKIN:** Rash

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Know that patient with a major psychotic disorder should not be administered istradefylline, because of the potential risk of exacerbating psychosis.
- Monitor patient for adverse reactions, especially central nervous system adverse effects. The most common effect leading to discontinuation of drug is dyskinesia.
- Monitor patient for hallucinations or psychotic behavior. If present, expect dosage to be decreased or drug discontinued.
- Be aware that patients taking istradefylline and one or more medications for the treatment of Parkinson's disease (including levodopa) may develop intense urges to binge-eat, gamble, have sex, or spend money excessively. If patient develops an impulse control disorder, notify prescriber. Dosage may have to be reduced or discontinued.
- Expect to monitor liver function tests. Dosage may require adjustment.
- Confirm smoking status in patients. Educate patients who smoke to inform prescribers.

## **PATIENT TEACHING**

- Advise patient that when istradefylline is taken with one or more drugs to treat Parkinson's disease (including levodopa), impulse control problems or compulsive behaviors may develop, such as intense urges to binge-eat, gamble, have sex, or spend money excessively. Tell patient to notify

prescriber if an impulse control disorder occurs. Also educate caregivers and family that this may occur and have them contact prescriber if present and patient is unaware of a lack of control.

- Women of childbearing potential should use contraception while taking istradefylline.
- Inform patient that drug may cause dyskinesia or exacerbate preexisting dyskinesia and to notify prescriber if present.
- Warn patient that istradefylline may cause hallucinations or psychotic behavior. If present, advise patient or family/caregiver to notify prescriber.
- Tell patient to inform prescribers of all medications taken, including over-the-counter drugs and herbal products such as St. John's wort.

## itraconazole

**Onmel, Sporanox**

### Class and Category

*Pharmacologic class:* Triazole derivative

*Therapeutic class:* Antifungal

### Indications and Dosages

- *To treat blastomycosis caused by Blastomyces dermatitidis and histoplasmosis caused by Histoplasma capsulatum*

### CAPSULES

**Adults.** *Initial:* 200 mg daily, increased, in 100 mg increments, as needed. *Maximum:* 400 mg daily, with

dosage greater than 200 mg given in divided doses twice daily.

- *To treat aspergillosis unresponsive to amphotericin B*

## **CAPSULES**

**Adults.** 200 to 400 mg daily, with dosage greater than 200 mg daily given in divided doses twice daily.

- *To treat life-threatening aspergillosis, blastomycosis, or histoplasmosis infections*

## **CAPSULES**

**Adults.** *Loading dose:* 200 mg given three times a day for three days followed by usual dosage for specific fungal infection and continued for a minimum of 3 months and until clinical parameters and laboratory tests indicate the active fungal infection has subsided.

- *To treat oropharyngeal candidiasis*

## **ORAL SOLUTION**

**Adults and adolescents.** 200 mg once a day or 100 mg twice daily for 7 to 14 days.

- *To treat fluconazole resistant oropharyngeal candidiasis*

## **ORAL SOLUTION**

**Adults and adolescents.** 100 mg twice daily for 2 to 4 wk.

- *To treat esophageal candidiasis*

## **ORAL SOLUTION**

**Adults.** 100 mg daily increased to 200 mg daily, if needed, for a minimum of 3 wk with treatment continued for 2 wk following resolution of symptoms.

- *To treat onychomycosis of toenails only or of toenails and fingernails in nonimmunocompromised patients*

## **CAPSULES**

**Adults.** 200 mg daily for 12 wk.

- *To treat onychomycosis of fingernails only in nonimmunocompromised patients*

## **CAPSULES**

**Adults.** 200 mg twice daily for 7 days; then repeated after 3 wk.

- *To treat onychomycosis of toenails only in non-immunocompromised patients*

## **TABLETS (ONMEL)**

**Adults.** 200 mg with a full meal once daily for 12 wk.

***DOSAGE ADJUSTMENT*** For some immunocompromised patients taking capsule form of drug, dosage may have to be increased because oral bioavailability of capsule form may be decreased.

## **Mechanism of Action**

Inhibits the synthesis of ergosterol, an essential component of fungal cell membranes, by binding with a cytochrome P-450 enzyme needed to convert lanosterol to ergosterol. Lack of ergosterol results in increased cellular permeability and leakage of cell contents. Itraconazole also may lead to fungal cell death by inhibiting fungal respiration under aerobic conditions.

## **Contraindications**

Concurrent therapy with avanafil, cisapride, disopyramide, dofetilide, dronedarone, eplerenone, ergot alkaloids, felodipine, HMG-CoA inhibitors (lovastatin and simvastatin), irinotecan, isavuconazole, ivabradine, levomethadyl, lomitapide, lovastatin, lurasidone, methadone, naloxegol, oral midazolam, pimozide, quinidine, ranolazine, simvastatin, ticagrelor, or triazolam; concurrent therapy with colchicine, fesoterodine, or solifenacin in patients with hepatic or renal impairment; concurrent therapy with eliglustat in patients who are poor or intermediate metabolizers of CYP2D6 or are taking moderate or strong CYP2D6 inhibitors; evidence of ventricular dysfunction, as in congestive heart failure (CHF) or a history of it (onychomycosis treatment); hypersensitivity to itraconazole or its components; pregnancy or contemplating pregnancy during onychomycosis treatment

## Interactions

### DRUGS

*alfentanil, budesonide, buspirone, busulfan, carbamazepine, cyclosporine, dexamethasone, digoxin, docetaxel, felodipine, fluticasone, indinavir, methylprednisolone, phenytoin, pimozide, rifabutin, ritonavir, saquinavir, sirolimus, tacrolimus, trimetrexate, vinca alkaloids:* Possibly increased blood levels of these drugs and serious adverse effects

*alprazolam, diazepam, oral midazolam, triazolam:* Elevated blood levels and possibly prolonged sedative effects of these drugs

*atorvastatin, lovastatin, simvastatin:* Increased blood levels of these drugs; possibly rhabdomyolysis

*avanafil, cisapride, colchicine, dofetilide, dronedarone, eplerenone, ergot alkaloids, felodipine, fesoterodine, halofantrine, irinotecan, isavuconazole, ivabradine, levomethadyl, lovastatin, lurasidone, methadone, midazolam (oral), naloxegol, pimozide, quinidine, ranolazine, simvastatin, solifenacin, ticagrelor, triazolam:* Possibly increased plasma levels of these drugs leading to potentially life-threatening cardiovascular complications such as cardiac arrest, prolonged QT interval, torsades de pointes, ventricular tachycardia, and sudden death  
*calcium channel blockers:* Possibly edema and increased risk of CHF; increased blood levels of these drugs  
*carbamazepine, isoniazid, nevirapine, phenobarbital, phenytoin, rifabutin, rifampin:* Possibly decreased blood itraconazole level  
*cilostazol; eletriptan; glucocorticosteroids such as budesonide, dexamethasone, fluticasone, and methylprednisolone; trimetrexate:* Possibly inhibited metabolism increasing concentrations of these drugs  
*clarithromycin, erythromycin, indinavir, ritonavir:* Possibly increased blood itraconazole level  
*ergot alkaloids:* Possibly increased plasma ergot alkaloid elevation, leading to cerebral ischemia and ischemia of the extremities  
*fentanyl:* Possibly increased plasma fentanyl level, causing potentially fatal respiratory depression  
*oral antidiabetic drugs such as repaglinide, saxagliptin:* Possibly increased blood levels of these drugs and risk of hypoglycemia  
*systemic contraceptive hormones:* Increased concentrations of these contraceptives  
*warfarin:* Increased anticoagulant effect of warfarin

## Adverse Reactions

**CNS:** Chills, confusion, dizziness, drowsiness, fatigue, fever, headache, hypoesthesia, paresthesia, peripheral neuropathy, tremor, vertigo

**CV:** **Cardiac failure**, chest pain, **congestive heart failure**, hypertension, hypertriglyceridemia, **hypotension**, **left ventricular failure**, peripheral edema, tachycardia

**EENT:** Altered sense of taste, blurred vision, diplopia, dysphonia, transient or permanent hearing loss, tinnitus

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, anorexia, constipation, diarrhea, elevated liver enzymes, flatulence, **hepatic failure**, **hepatitis**, **hepatotoxicity**, hyperbilirubinemia, indigestion, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Erectile dysfunction, menstrual irregularities, pollakiuria, renal impairment, urinary incontinence

**HEME:** **Leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, myalgia

**RESP:** Cough, dyspnea, **pulmonary edema**

**SKIN:** Acute generalized exanthematous pustulosis, alopecia, diaphoresis, **erythema multiforme**, **exfoliative dermatitis**, leukocytoclastic vasculitis, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia**, **hypokalemia**, **hypomagnesemia**, serum sickness

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as congenital abnormalities.
- Drug should not be used to treat onychomycosis in pregnant patients or in women contemplating pregnancy.

## **LACTATION**

- Drug is present in breast milk
- Mother who is HIV negative should check with prescriber before breastfeeding.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## **REPRODUCTION**

- Drug should not be used in women of childbearing age for treatment of onychomycosis unless they are using effective measures to prevent pregnancy and they begin therapy on the second or third day following the onset of menses.
- Highly effective contraception should be continued throughout drug therapy and for 2 months following drug discontinuation.

## **Nursing Considerations**

- Know that itraconazole should not be used for the treatment of onychomycosis in patients with evidence of ventricular dysfunction such as congestive heart failure (CHF) or a history of CHF. If signs and symptoms of CHF develops during therapy, notify prescriber immediately and expect drug to be discontinued.
- Use itraconazole with extreme caution in patients with risk factors for CHF, such as ischemic or valvular heart disease, renal failure and other edematous disorders, or significant pulmonary disease such as chronic obstructive pulmonary disease because of increased risk of developing CHF during itraconazole treatment.
- Use itraconazole cautiously in patients with hypersensitivity to other azole antifungals (because cross-hypersensitivity is unknown) and in patients with hepatic or renal impairment.
- Know that because itraconazole has been linked to serious adverse cardiac and hepatic effects, expect to send appropriate nail specimens for laboratory testing to confirm onychomycosis before beginning therapy.

**WARNING** Keep in mind that itraconazole is a potent inhibitor of the cytochrome P-450 3A4 (CYP3A4) isoenzyme system, which may increase blood levels of drugs metabolized by this system. Patients taking such drugs as cisapride with itraconazole or other CYP3A4 inhibitors have experienced life-threatening cardiovascular complications, such as prolonged QT interval, torsades de pointes, and ventricular tachycardia, as well as sudden death.

- Administer itraconazole capsules (not oral solution) and tablets with a meal to ensure maximal absorption.
- Know that capsules and oral solution forms are not interchangeable because drug exposure is greater with oral solution. Tablet form is used only for the treatment of onychomycosis of the toenail.
- Keep in mind that a patient with AIDS may have hypochlorhydria, which reduces drug absorption. For such a patient, expect to administer higher doses of itraconazole.
- Monitor liver enzymes in patients with impaired hepatic function and those who have experienced hepatotoxicity with other drugs.
- Be aware that if patient develops signs and symptoms of peripheral neuropathy or CHF, such as dyspnea, fatigue and peripheral edema, expect to discontinue drug.
- Assess patient for rash every 8 hours during therapy; notify prescriber if rash occurs.
- Know that if patient also receives warfarin, monitor PT and assess patient for signs and symptoms of bleeding.
- Keep in mind that if patient also receives digoxin, monitor blood digoxin level as appropriate to detect toxic level, and assess patient for signs and symptoms of digitalis toxicity, such as nausea and yellow vision.
- Know that if a patient with cystic fibrosis does not respond to itraconazole therapy, alternative therapy should be considered.

## **PATIENT TEACHING**

- Instruct patient to take itraconazole capsules or tablets with a meal and to swallow capsules whole, but oral solution without food.
- Tell patient with diabetes who takes an oral antidiabetic drug to check his blood glucose level often because of the increased risk of hypoglycemia.
- Advise patient to avoid taking antacids with oral itraconazole.
- Advise patient to notify prescriber immediately of changes in other drugs, such as new drugs and dosage changes.
- Advise patient to notify prescriber immediately about abdominal pain, diarrhea, headache, hearing loss, nausea, peripheral neuropathy, or vomiting.
- Instruct patient to stop itraconazole and notify prescriber immediately if he experiences an allergic reaction.
- Tell him to stop itraconazole and notify prescriber immediately if he notices fluid retention.
- Instruct patient to notify prescriber if he experiences signs of liver problems, such as abdominal pain, dark urine, fatigue, loss of appetite, pale stools, weakness, or yellow eyes or skin.
- Caution patient to avoid performing hazardous activities such as driving until CNS effects such as dizziness or change in vision are not present.
- Tell women of childbearing age to begin therapy on the second or third day following the onset of menses. Also, advise patient to use effective contraception to prevent pregnancy during itraconazole therapy and for 2 months following the end of treatment. Tell patient to notify prescriber immediately if pregnancy is suspected or occurs. Inform women of childbearing age that itraconazole should not be given to pregnant women or women contemplating pregnancy for the treatment of onychomycosis.
- Caution breastfeeding patient to consult prescriber about continuation of breast-feeding during itraconazole therapy.

**ivabradine**

**Corlanor**

## Class and Category

*Pharmacologic class:* Nucleotide-gated channel blocker

*Therapeutic class:* Cardiac pacemaker regulator

## Indications and Dosages

- *To reduce risk of hospitalization for worsening heart failure in patients with stable, symptomatic chronic heart failure who have a left ventricular ejection fraction of 35% or less, who are in sinus rhythm with a resting heart rate of 70 beats/minute or more and either are on maximally tolerated doses of beta-blockers or have a contraindication to beta-blocker use*

### ORAL SOLUTION, TABLETS

**Adults. Initial:** 5 mg twice daily with meals followed by a dosage adjustment in 2 weeks to achieve a resting heart rate between 50 and 60 beats/minute. *Maximum:* 7.5 mg twice daily.

***DOSAGE ADJUSTMENT*** For a patient with a resting heart rate greater than 60 beats/minute, dosage increased by 2.5 mg given twice daily up to a maximum dose of 7.5 mg twice daily, as needed. For a patient with a heart rate between 50 and 60 beats/min, dose maintained. For a patient with a resting heart rate below 50 beats/minute or who experience signs and symptoms of bradycardia, dosage decreased by 2.5 mg given twice daily; if current dose is already 2.5 mg twice daily, drug discontinued.

- *To treat stable symptomatic heart failure due to dilated cardiomyopathy in children who are in sinus rhythm with an elevated heart rate*

## ORAL SOLUTION, TABLETS

**Children weighing 40 kg (88 lb) or greater.** *Initial:* 2.5 mg twice daily with food. Dose adjusted at 2-wk intervals by 2.5 mg to target a heart rate reduction of at least 20%, if tolerated. *Maximum:* 7.5 mg twice daily.

## ORAL SOLUTION

**Children age 6 months and older weighing less than 40 kg (88 lb).** *Initial:* 0.05 mg/kg twice daily with food. Dose adjusted at 2-wk intervals by 0.05 mg/kg to target a heart rate reduction of at least 20%, if tolerated. *Maximum:* 0.2 mg/kg twice daily (patients 6 months to less than 1 yr); 0.3 mg/kg twice daily (patients 1 yr and older up to 7.5 mg twice daily.)

***DOSAGE ADJUSTMENT*** For children who develop bradycardia, dosage reduced to previous titration step. If child is at the recommended initial dosage, dosage reduced to 0.02 mg/kg twice daily.

## Mechanism of Action

Blocks the hyperpolarization-activated cyclic nucleotide-gated (HCN) channel responsible for the cardiac pacemaker, which regulates heart rate. This results in a reduction in heart rate

## Contraindications

Acute decompensated heart failure; clinically significant bradycardia or hypotension; concomitant use of strong cytochrome P-450 3A4 (CYP3A4) inhibitors; hypersensitivity to ivabradine or its components; pacemaker dependence; severe hepatic impairment; sick

sinus syndrome, sinoatrial block, or third degree AV block, unless a functioning demand pacemaker is present

## Interactions

### DRUGS

*CYP3A4 inducers such as barbiturates, phenytoin, rifampicin, St. John's wort:* Decreased ivabradine plasma concentrations decreasing effectiveness  
*moderate and strong CYP3A4 inhibitors such as azole antifungals, diltiazem, HIV protease inhibitors, macrolide antibiotics, nefazodone, verapamil:* Increased ivabradine plasma concentrations, which may exacerbate bradycardia and conduction disturbances  
*negative chronotropes such as amiodarone, beta-blockers, digoxin:* Increased risk of bradycardia

### FOODS

*grapefruit juice:* Increased ivabradine plasma concentrations, which may exacerbate bradycardia and conduction disturbances

## Adverse Reactions

**CNS:** Syncope, vertigo

**CV:** Atrial fibrillation, bradycardia, heart block, hypertension, hypotension, sinus arrest, torsades de pointes, ventricular fibrillation and tachycardia

**EENT:** Diplopia, colored bright lights, halos, image decomposition such as kaleidoscopic or stroboscopic effects, multiple images, transiently enhanced brightness in a limited area of the visual field, visual impairment

**SKIN:** Erythema, pruritus, rash, urticaria

**Other:** **Angioedema**

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Be aware that pregnant women with congestive heart failure, who are started on drug, especially during the first trimester, should be followed closely for destabilization that could result from a decreased heart rate.
- Monitor pregnant women with chronic heart failure in third trimester for preterm birth.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

### **REPRODUCTION**

- Advise women of childbearing age to use effective contraception during drug therapy.

## **Nursing Considerations**

- Be aware that ivabradine should not be given to patients with demand pacemakers set to a rate of 60 beats/minute or greater because these patients will not be able to achieve a target heart rate of less than 60 beats/minute.
- Know that although drug is not contraindicated, it is not recommended for use in patients with a second degree heart block unless a functioning demand pacemaker is in place.

- Monitor patient's cardiac rhythm regularly because ivabradine increases the risk of atrial fibrillation and conduction disturbances. Also monitor patient's heart rate, because drug may cause bradycardia. Risk factors for bradycardia include conduction defects, sinus node dysfunction, ventricular dysfunction, and use of other negative chronotropic drugs such as amiodarone, digoxin, diltiazem, or verapamil. Be aware that bradycardia may increase risk of prolonged QT interval, which may lead to life-threatening ventricular arrhythmias. Notify prescriber if arrhythmias such as atrial fibrillation or conduction disturbances occurs or the patient's heart rate drops below 50 beats/minute. Expect drug to be discontinued in these situations.

## PATIENT TEACHING

- Instruct patient to take ivabradine with meals.
- Inform patients having difficulty swallowing tablets that an oral solution is available. If oral solution is used, teach patient how to prepare and administer oral solution (except children should not be self-administering). Remind patient and parents/caregivers to use a calibrated oral syringe and a medicine cup to avoid dosing errors. Drug dose should not be doubled up if child spits out the drug or drug is forgotten to be taken at the prescribed time. Medicine cup should be thrown away after drug is drawn up in the syringe.

**WARNING** Advise female patients of childbearing age that ivabradine may cause fetal toxicity and an effective contraceptive must be used during therapy. Tell patient to notify prescriber immediately if pregnancy is suspected or occurs.

- Instruct patient to notify all prescribers of ivabradine therapy.
- Tell patient to notify prescriber if pulse becomes irregular or less than 50 beats/minute or visual disturbances occurs.

**ixekizumab**

**Taltz**

## Class and Category

*Pharmacologic class:* Interleukin-17 A antagonist

*Therapeutic class:* Immunomodulator

## Indications and Dosages

- *To treat moderate-to-severe plaque psoriasis in patients who are candidates for phototherapy or systemic therapy*

### SUBCUTANEOUS INJECTION

**Adults. Initial:** 160 mg (two 80-mg injections) at wk 0, followed by 80 mg at wks 2, 4, 6, 8, 10, and 12; then 80 mg every 4 wk.

- *To treat active psoriatic arthritis; to treat active ankylosing spondylitis*

### SUBCUTANEOUS INJECTION

**Adults. Initial:** 160 mg (two 80-mg injections), followed by 80 mg every 4 wk.

***DOSAGE ADJUSTMENT*** For patient with psoriatic arthritis with coexistent moderate to severe plaque psoriasis, the dosing regimen for plaque psoriasis should be used.

## Mechanism of Action

Selectively binds with the interleukin 17A cytokine and inhibits its interaction with the IL-17 receptor. This inhibits the release of proinflammatory cytokines and chemokines involved in normal inflammatory and immune responses.

Binding of IL-17 receptors prevents inflammation-related signals from being relayed, which reduces the inflammatory response and relieves signs and symptoms of plaque psoriasis

## Incompatibilities

Don't mix ixekizumab with other drugs.

## Contraindications

Hypersensitivity to ixekizumab or its components

## Interactions

### DRUGS

*CYP450 substrates with a narrow therapeutic index such as cyclosporine, warfarin:* Possibly decreased plasma levels of these drugs with decreased effectiveness

*live vaccines:* Increased risk of adverse vaccine effects

## Adverse Reactions

**EENT:** Conjunctivitis, oral candidiasis, rhinitis

**GI:** Crohn's disease (new onset or exacerbation), nausea, ulcerative colitis (new onset or exacerbation)

**HEME:** **Neutropenia, thrombocytopenia**

**RESP:** Upper respiratory infections

**SKIN:** Tinea infections, urticaria

**Other:** **Anaphylaxis, angioedema**, anti-ixekizumab antibodies, flu-like symptoms, infection including activation of latent infections such as tuberculosis, injection-site reactions such as erythema and pain

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Check patient's immunization history and make sure all age-appropriate immunizations according to current guidelines have been administered prior to initiating ixekizumab therapy. Live vaccines should be avoided during ixekizumab therapy.
- Make sure patient has a tuberculin skin test before therapy starts. If skin test is positive, tuberculosis treatment will need to be started before ixekizumab can begin. Even patients who have tested negative for tuberculosis may develop tuberculosis during therapy. Monitor patient for low-grade fever, persistent cough, and wasting or weight loss; report such findings to prescriber.
- Know that if patient has evidence of an active infection when drug is prescribed, therapy shouldn't start until infection has been treated. Monitor patients for the development of infections such as conjunctivitis, oral candidiasis, tinea infections, and upper respiratory tract infections during therapy; report such findings to prescriber. Know that if a patient develops a serious infection or does not respond to treatment prescribed for the infection, ixekizumab may have to be temporarily withheld until the infection is resolved.
- Remove autoinjector or prefilled syringe from the refrigerator and allow about 30 minutes for drug to reach room temperature. Don't remove the needle cap during this time. Inspect solution for particulate matter or discoloration. Solution should appear clear and colorless to slightly

yellow. Because the solution does not contain a preservative, discard any unused solution.

- Administer ixekizumab as a subcutaneous injection using either the autoinjector or prefilled syringe. Inject the full amount (1 ml), which provides 80 mg of ixekizumab into any quadrant of the abdomen, thighs, or upper arms. Rotate injection sites and do not inject into areas where the skin is affected by psoriasis or is bruised, erythematous, or indurated.

**WARNING** Monitor patient closely for hypersensitivity. If a serious reaction occurs, such as angioedema or urticaria, discontinue drug immediately, notify prescriber, and provide supportive care, as prescribed.

- Monitor patient closely for evidence of inflammatory bowel disease. Know that Crohn's disease and ulcerative colitis may occur. During treatment, monitor patient for onset or exacerbation of inflammatory bowel disease.

## **PATIENT TEACHING**

- Instruct patient or caregiver on how to administer drug subcutaneously, if self-administration is prescribed. Provide instructions on how to use the autoinjector or prefilled syringe correctly. Tell patient how to dispose of syringe or autoinjector properly and to keep out of reach of children and pets, including those already used.
- Tell patient to keep drug refrigerated in between doses but to allow the drug to warm to room temperature for about 30 minutes before administering. Tell patient to inject the full amount of the drug into any quadrant of the abdomen, thighs, or upper arms. Stress importance of avoiding areas where the skin is affected by psoriasis or is bruised, indurated, or red and to rotate sites. Alert him to the possibility of experiencing redness or pain at injection site, but advise him that these are not usually severe.
- Review the signs and symptoms of an allergic reaction (difficulty breathing, hives, swollen face) and tell patient to seek emergency care immediately if these occur.
- Inform patient that infections, including activation of latent infections such as tuberculosis, may occur during ixekizumab therapy. Instruct him to report persistent, severe, or unusual signs and symptoms to prescriber. Advise patient to avoid people with infections.

- Alert patient that irritable bowel syndrome may occur or be aggravated by ixekizumab therapy. Tell him to notify prescriber of adverse reactions such as abdominal distention or pain or diarrhea that is persistent or severe.
- Warn patient not to receive immunizations that contain live vaccines while taking ixekizumab.

# J K L

## ketoprofen

### Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic

### Indications and Dosages

- *To treat symptoms of osteoarthritis or rheumatoid arthritis*

#### CAPSULES

**Adults.** *Initial:* 75 mg three times daily or 50 mg four times daily. *Maximum:* 300 mg daily.

#### E.R. CAPSULES

**Adults.** *Maintenance:* 200 mg daily.

- *To relieve mild to moderate pain; pain associated with dysmenorrhea*

#### TABLETS

**Adults.** *Initial:* 25 to 50 mg every 6 to 8 hr as needed. May be increased to 75 mg every 6 to 8 hr, as needed.  
*Maximum:* 300 mg daily.

**DOSAGE ADJUSTMENT** For debilitated, elderly, and small patients, dosage reduced. For patients with mild renal dysfunction, maximum daily dose reduced to 150 mg daily; for patients with more severe renal impairment (glomerular filtration rate less than 25 ml/min), end-stage renal disease, or liver dysfunction, maximum daily dose reduced to 100 mg.

## Mechanism of Action

Blocks activity of cyclooxygenase, the enzyme needed for prostaglandin synthesis. Prostaglandins, important mediators of inflammatory response, cause local vasodilation with pain and swelling. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammatory symptoms and relieves pain.

## Contraindications

Aspirin or NSAID-induced asthma, bronchospasm, nasal polyps, rhinitis, or urticaria; hypersensitivity to ketoprofen or its components; pain with coronary artery bypass graft (CABG) surgery

## Interactions

### DRUGS

*aspirin, other NSAIDs:* Increased risk of bleeding and adverse GI effects

*corticosteroids, potassium supplements:* Increased risk of adverse GI effects

*diuretics (loop, potassium-sparing, and thiazide):*

Decreased diuretic and antihypertensive effects

*lithium:* Increased blood lithium level and possibly toxicity

*methotrexate*: Decreased methotrexate clearance, increased risk of methotrexate toxicity

*probenecid*: Possibly increased blood level, effectiveness, and risk of toxicity of ketoprofen

*warfarin*: Synergistic effect increasing risk of serious GI bleeding higher than users of either drug alone

## **ACTIVITIES**

*alcohol use*: Increased risk of adverse GI effects

## **Adverse Reactions**

**CNS**: **CVA**, headache, irritability, nervousness, **seizures**

**CV**: Edema, hypertension, **MI**, tachycardia

**EENT**: Tinnitus, vision changes

**GI**: Abdominal pain, anorexia, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, elevated liver enzymes, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, **GI bleeding** and ulceration, **hepatic failure**, hiatal hernia, indigestion, **melena**, nausea, **perforation of intestine or stomach**, stomatitis, vomiting

**GU**: **Acute renal failure**, decreased urine output

**HEME**: **Agranulocytosis**, anemia, easy bruising, **hemolytic anemia**, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**RESP**: **Asthma**, **respiratory depression**

**SKIN**: **Erythema multiforme**, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, rash

**Other**: **Anaphylaxis**, **angioedema**, rapid weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use ketoprofen with extreme caution in patients with history of GI bleeding or ulcer disease because NSAIDs, such as ketoprofen, increase risk of GI bleeding and ulceration. Expect to use ketoprofen for shortest time possible in these patients.
- Be aware that serious GI tract bleeding, perforation, and ulceration may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use ketoprofen cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk.

- Monitor patient—especially if he's elderly or receiving long-term ketoprofen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes, as ordered, because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, liver necrosis, and hepatic failure. Monitor BUN and serum creatinine levels in elderly patients, patients taking ACE inhibitors or diuretics, and patients

with heart failure or impaired renal function; drug may cause renal failure in these patients.

- Monitor CBC for decreased hematocrit and hemoglobin level because drug may worsen anemia.

**WARNING** If patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of ketoprofen may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because ketoprofen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Be aware that if patient takes acetaminophen, BUN level, fluid intake and output, and serum creatinine level should be monitored for evidence of adverse renal effects.

## **PATIENT TEACHING**

- Instruct patient to take ketoprofen with food or after meals to prevent GI upset. Advise him to take drug with a full glass of water and to avoid lying down for 15 to 30 minutes afterward to prevent drug from lodging in esophagus and causing irritation.
- Advise patient to swallow drug whole and not to break, chew, crush, or open capsules.
- Instruct patient to avoid alcohol, aspirin, and aspirin-containing products while taking ketoprofen to decrease risk of adverse GI effects.
- Tell patient not to take more drug than prescribed because stomach bleeding may occur.
- Warn patient taking an anticoagulant to watch for and immediately report bleeding problems, such as bloody or tarry stools and bloody vomitus.
- Inform patient that he may be nervous and irritable while taking ketoprofen.

- Instruct patient to notify prescriber immediately if he develops decreased urine output, dark brown or yellow urine, rash, or signs of fluid retention, including swelling of extremities and unexplained rapid weight gain.
- Caution pregnant patient not to take NSAIDs such as ketoprofen during last trimester because drug may cause premature closure of the ductus arteriosus.
- Explain that ketoprofen may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, shortness of breath, slurring of speech, or weakness.
- Explain that ketoprofen may increase risk of serious adverse GI reactions; emphasize importance of seeking immediate medical attention for such signs and symptoms as abdominal or epigastric pain, black or tarry stools, indigestion, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.

## ketorolac tromethamine

**Sprix, Toradol**

### Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic

### Indications and Dosages

- *To treat moderate to severe pain that requires analgesia at the opioid level*

### **TABLETS**

**Adults ages 17 to 64 following parenteral therapy.**

*Initial:* 20 mg as single dose, followed by 10 mg every 4 to 6 hr as needed, up to four times a day. *Maximum:* 40 mg daily for no more than 5 days.

**DOSAGE ADJUSTMENT** For elderly patients (65 years or older), patients with impaired renal function, or patients weighing less than 50 kg (110 lb), initial dose reduced to 10 mg and given after parenteral therapy.

## **I.M. INJECTION**

**Adults ages 17 to 64.** *Initial:* 60 mg as single dose, followed by oral ketorolac if needed; or 30 mg every 6 hr as needed. *Maximum:* 120 mg daily for no more than 5 days.

**DOSAGE ADJUSTMENT** For elderly patients (65 years and older), patients with impaired renal function, or patients weighing less than 50 kg (110 lb), initial dose reduced to 30 mg, followed by oral ketorolac if needed; or 15 mg every 6 hr as needed, up to maximum of 60 mg daily for no more than 5 days.

## **I.V. INJECTION**

**Adults ages 17 to 64.** *Initial:* 30 mg given over no less than 15 sec as single dose, followed by oral ketorolac if needed; or 30 mg every 6 hr as needed. *Maximum:* 120 mg daily for no more than 5 days.

**DOSAGE ADJUSTMENT** For elderly patients (65 years and over), patients with impaired renal function, or patients weighing less than 50 kg (110 lb), initial dose reduced to 15 mg, followed by oral ketorolac if needed; or 15 mg every 6 hr as needed, up to maximum of 60 mg daily for no more than 5 days.

## **NASAL SPRAY (SPRIX)**

**Adults less than 65 years of age.** 15.75 mg (1 spray) in each nostril every 6 to 8 hr. *Maximum:* 126 mg (four doses) daily for no more than 5 days.

**DOSAGE ADJUSTMENT** For elderly patients (65 years and older), patients with impaired renal function, or patients weighing less than 50 kg (110 lb), 15.75 mg in only one nostril every 6 to 8 hr with maximum dose of 63 mg (four doses) daily for no more than 5 days.

Route	Onset	Peak	Duration
P.O.	30-60 min	2-3 hr	5-6 hr
I.M., I.V.	30-60 min	1-2 hr	4-6 hr
Nasal	30-60 min	Unknown	6-8 hr

## Mechanism of Action

Blocks cyclooxygenase, an enzyme needed to synthesize prostaglandins. Prostaglandins mediate inflammatory response and cause local vasodilation, pain, and swelling. They also promote pain transmission from periphery to spinal cord. By blocking cyclooxygenase and inhibiting prostaglandins, this NSAID reduces inflammation and relieves pain.

## Contraindications

Active peptic ulcer disease or recent GI bleeding or perforation; advanced renal impairment or risk of renal impairment due to volume depletion; cerebrovascular bleeding, hemorrhagic diathesis, incomplete hemostatsis, or high risk of bleeding; history of asthma, urticaria, or other allergic-type reactions after taking aspirin or other NSAIDs; hypersensitivity to ketorolac tromethamine or its components; labor and delivery; postoperative pain after

coronary artery bypass graft (CABG) surgery; use as a prophylactic analgesic before any major surgery

## Interactions

### DRUGS

*ACE inhibitors, angiotensin II receptor antagonists:*

Decreased antihypertensive effect of these drugs; increased risk of decreased renal function in patients who are elderly or volume depleted or have existing renal impairment

*anticoagulants such as warfarin, platelet aggregation*

*inhibitors such as aspirin, pentoxifylline, selective*

*serotonin reuptake inhibitors, serotonin norepinephrine*

*reuptake inhibitors:* Increased risk of serious bleeding

*antiepileptic drugs such as carbamazepine, phenytoin:*

Increased risk of seizures

*aspirin and other salicylates, other NSAIDs:* Increased risk of GI adverse reactions and bleeding, including GI toxicity

*cyclosporine:* Increased risk of cyclosporine-induced nephrotoxicity

*digoxin:* Increased digoxin levels with risk of digoxin toxicity

*diuretics:* Reduced effects of loop and thiazide diuretics in some patients

*such as aspirin, pentoxifylline, selective serotonin reuptake*

*inhibitors, serotonin norepinephrine reuptake inhibitors:*

*lithium:* Possibly increased blood lithium level and increased risk of lithium toxicity

*methotrexate:* Possibly methotrexate toxicity

*pemetrexed:* Increased risk of pemetrexed-associated myelosuppression and GI and renal toxicity

*probenecid:* Decreased elimination of ketorolac, increased risk of adverse effects

## ACTIVITIES

*alcohol use:* Increased risk of adverse GI effects

## Adverse Reactions

**CNS:** Aseptic meningitis, cerebral hemorrhage, coma, CVA, dizziness, drowsiness, headache, psychosis, seizures

**CV:** Edema, hypertension

**EENT:** Laryngeal edema, stomatitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain; acute pancreatitis; bloating; constipation; diarrhea; diverticulitis; elevated liver enzymes; flatulence; GI bleeding, perforation, or ulceration; hepatitis; hepatic failure; jaundice; indigestion; nausea; vomiting; worsening of inflammatory bowel disease

**GU:** Interstitial nephritis, renal failure, urine retention

**HEME:** Agranulocytosis, anemia, aplastic or hemolytic anemia, eosinophilia, leukopenia, lymphadenopathy, pancytopenia, thrombocytopenia

**RESP:** Bronchospasm, pneumonia, respiratory depression

**SKIN:** Diaphoresis, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, hyperkalemia, hyponatremia, injection-site pain, sepsis, unusual weight gain

## Childbearing Considerations

### PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

## **LABOR & DELIVERY**

- Drug may affect fetal circulation and inhibit uterine contractions.
- Use of drug is contraindicated during labor and delivery.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **REPRODUCTION**

- Drug may affect fertility by delaying or preventing rupture of ovarian follicles.
- Drug should not be given to women who are planning to conceive or who are having difficulty conceiving.

## **Nursing Considerations**

- Be aware that NSAIDs like ketorolac should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Know that the risk of heart failure increases with ketorolac use because drug is a NSAID. This class of drugs should not be used in patients with severe heart failure but, if unavoidable, monitor patient for worsening of heart failure.
- Read ketorolac label carefully. Don't use I.M. form for I.V. route. Know that ketorolac isn't for epidural or intrathecal use.

- Inject I.M. ketorolac slowly, deep into a large muscle mass. Monitor site for bleeding, bruising, or hematoma.
- Give I.V. injection over at least 15 seconds.
- Notify prescriber if pain relief is inadequate or if breakthrough pain occurs between doses because supplemental doses of an opioid analgesic may be required.

**WARNING** Monitor liver enzymes, as ordered. If elevated levels persist or worsen, notify prescriber and expect to stop drug, as ordered, to prevent hepatic impairment.

**WARNING** Monitor patients with a history of peripheral edema, heart failure, or hypertension for adequate fluid balance because drug can promote fluid retention and worsen these conditions. Assess patient for decreased activity tolerance, dyspnea, edema, and unexplained rapid weight gain. Notify prescriber if such symptoms develop.

- Use ketorolac with extreme caution in patients with history of GI bleeding or ulcer disease because NSAIDs like ketorolac increase risk of GI bleeding and ulceration. Use ketorolac in these patients for shortest length of time possible.
- Know that serious GI tract bleeding and ulceration and perforation of intestine or stomach can occur without warning or symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Monitor patient with history of inflammatory bowel disease, such as Crohn's disease or ulcerative colitis, because ketorolac may worsen these conditions.
- Use ketorolac cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy because drug can lead to onset of hypertension or worsen existing hypertension.

**WARNING** Monitor patient closely for thrombotic events including MI and stroke because NSAIDs such as ketorolac increase risk. These events may occur early in treatment and risk increases with duration of use. Be

aware that these events have occurred even in patients who do not have a history of or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, slurring of speech, shortness of breath, or weakness. If any signs and symptoms develop, withhold ketorolac, alert prescriber immediately, and provide supportive care, as prescribed.

- Monitor patient—especially if elderly—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor BUN and serum creatinine levels in the elderly; patients with heart failure, hepatic impairment, or impaired renal function; and those who are taking ACE inhibitors or diuretics because drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.

**WARNING** In patient who has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC) and assess for evidence of infection because ketorolac has anti-inflammatory and antipyretic actions that may mask signs and symptoms, such as fever and pain.

- Assess patient's skin routinely for rash or other evidence of hypersensitivity reactions because ketorolac is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

## **PATIENT TEACHING**

- Alert patient that tablets are not used as initial therapy but follow an intramuscular or intravenous injection. Instruct patient to take ketorolac tablets with an antacid, a meal, or a snack to prevent stomach upset.

Advise him to take drug with a full glass of water and to stay upright for at least 15 minutes afterward.

- Teach patient how to prime bottle and administer nasal spray form, if prescribed. Remind patient that nasal spray form is not to be inhaled. Tell patient not to use any single nasal spray bottle for more than 1 day, as it will not deliver the intended dose after 24 hours.
- Advise patient not to take aspirin, other NSAIDs, or other salicylates while taking ketorolac without consulting prescriber. Urge patient to limit use of acetaminophen to only a few days during ketorolac therapy and to notify prescriber of use.
- Caution patient not to use ketorolac for more than 5 days, as serious adverse effects may occur.
- Instruct him to immediately report blood in urine, easy bruising, itching, rash, swelling, or yellow eyes or skin.
- Caution pregnant patient that NSAIDs like ketorolac shouldn't be taken during last trimester because drug may cause premature closure of the ductus arteriosus.
- Explain that ketorolac may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, edema, shortness of breath, slurring of speech, unexplained weight gain, or weakness.
- Tell patient that ketorolac also may increase risk of serious adverse GI reactions; stress importance of seeking immediate medical attention if signs or symptoms occur, such as abdominal or epigastric pain, black tarry stools, indigestion, and vomiting blood or coffee ground material.
- Alert patient to the possibility of serious skin reactions, although rare, occurring with ketorolac therapy. Urge patient to seek immediate medical attention if signs or symptoms occur, such as blisters, fever, a rash, or other signs of hypersensitivity, such as itching.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol while taking ketorolac.
- Encourage patient to have dental procedures performed before starting drug therapy because of increased risk of bleeding.
- Teach patient proper oral hygiene measures, and encourage him to use a soft-bristled toothbrush while taking ketorolac.

# labetalol hydrochloride

## Class and Category

*Pharmacologic class:* Noncardioselective beta-blocker/alpha<sup>1</sup> blocker

*Therapeutic class:* Antihypertensive

## Indications and Dosages

➤ *To manage hypertension*

### **TABLETS**

**Adults.** *Initial:* 100 mg twice daily, increased by 100 mg twice daily as needed and tolerated every 2 to 3 days.

*Maintenance:* 200 to 400 mg twice daily.

➤ *To manage severe hypertension*

### **TABLETS**

**Adults.** 1.1 to 2.4 g daily in divided doses twice daily or three times daily with dosage titration not exceeding 200 mg twice daily.

### **I.V. INFUSION**

**Adults.** 2 mg/min until desired response occurs.

### **I.V. INJECTION**

**Adults.** 20 mg given over 2 min; additional doses given in increments of 40 to 80 mg every 10 min as indicated until

desired response occurs. *Maximum:* 300 mg.

Route	Onset	Peak	Duration
P.O.	20 min-2 hr	1-4 hr	8-24 hr
I.V.	2-5 min	5-15 min	2-4 hr

## Mechanism of Action

Selectively blocks  $\alpha_1$  and  $\beta_2$  receptors in vascular smooth muscle and  $\beta_1$  receptors in heart to reduce blood pressure and peripheral vascular resistance. Potent beta blockade prevents reflex tachycardia, which commonly occurs when alpha blockers reduce cardiac output, resting heart rate, or stroke volume.

## Incompatibilities

Don't dilute labetalol in sodium bicarbonate solution or give through same I.V. line as alkaline drugs, such as furosemide; doing so may cause white precipitate to form.

## Contraindications

Bronchial asthma, cardiogenic shock, hypersensitivity to labetalol or its components, obstructive airway disease, other conditions associated with severe and prolonged hypotension, overt heart failure, second- or third-degree heart block, severe bradycardia

## Interactions

### DRUGS

*calcium antagonist of verapamil type*: Increased risk of adverse reactions

*cimetidine*: Possibly increased labetalol concentration and effects

*epinephrine*: Possibly unresponsiveness to usual doses of epinephrine

*halothane anesthesia*: Increased risk of hypotension

*nitroglycerin*: Blunted reflex tachycardia

*other beta blocker agonists*: Possibly blunted bronchodilator effect of these drugs in patients with bronchospasm

*tricyclic antidepressants*: Increased risk of tremor

## Adverse Reactions

**CNS**: Anxiety, confusion, depression, dizziness, drowsiness, fatigue, paresthesia, syncope, vertigo, weakness, yawning

**CV**: **Bradycardia**, chest pain, edema, **heart block**, **heart failure**, **hypotension**, orthostatic hypotension, **ventricular arrhythmias**

**EENT**: Nasal congestion, taste perversion

**GI**: Elevated liver enzymes, **hepatic necrosis**, **hepatitis**, indigestion, jaundice, nausea, vomiting

**GU**: Ejaculation failure, impotence

**RESP**: Dyspnea, wheezing

**SKIN**: Pruritus, rash, scalp tingling

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, bradycardia, hypoglycemia, hypotension, and respiratory depression have occurred in infants of mothers who were treated with the drug for hypertension during pregnancy.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- During I.V. labetalol use, expect to monitor blood pressure according to facility policy, usually every 5 minutes for 30 minutes, then every 30 minutes for 2 hours, and then every hour for 6 hours.
- Keep patient in supine position for 3 hours after I.V. administration.

**WARNING** Be aware that labetalol masks common signs of shock.

- Monitor blood glucose level in diabetic patient because labetalol may conceal symptoms of hypoglycemia.
- Be aware that stopping labetalol tablets abruptly after long-term therapy could result in angina, MI, or ventricular arrhythmias. Expect to taper dosage over 2 weeks while monitoring response.

## PATIENT TEACHING

- Advise patient to report confusion, difficulty breathing, rash, slow pulse, and swelling in arms or legs.
- Caution patient not to stop drug abruptly because doing so could cause angina and rebound hypertension.
- Suggest that patient minimize effects of orthostatic hypotension by avoiding sudden position changes, rising to a sitting or standing position slowly, and taking labetalol at bedtime, if approved by prescriber.
- Instruct diabetic patient to check blood glucose level often and to be alert for signs and symptoms of hypoglycemia.

- Inform patient that scalp tingling may occur early in treatment but is transient.
- Urge patient to avoid alcohol during labetalol therapy.
- Advise patient to inform eye healthcare provider if he needs cataract surgery because intraoperative floppy iris syndrome has occurred during cataract surgery in some patients treated with the class of drugs of which labetalol is a member.

## lacosamide

### Vimpat

## Class and Category

*Pharmacologic class:* Functionalized amino acid

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

➤ *To treat partial-onset seizures*

### ORAL SOLUTION, TABLETS

**Adults and adolescents age 17 and over.** 100 mg twice daily, increased by 50 mg twice daily every week to recommended maintenance dose. Alternatively, 200 mg given as single loading dose, followed 12 hr later by 100 mg twice daily for 1 wk. Dosage increased at weekly intervals by 50 mg twice daily, as needed, up to recommended maintenance dose. *Maintenance:* 150 to 200 mg twice daily.

**Children ages 4 to 17 weighing 50 kg (110 lb) or more.** 50 mg twice daily, increased by 50 mg twice daily every week to recommended maintenance dose.

*Maintenance:* 150 mg to 200 mg twice daily.

**Children ages 4 to 17 weighing 30 kg (66 lb) to less than 50 kg (110 lb).** 1 mg/kg twice daily, increased by 1 mg/kg twice daily every week to recommended maintenance dose. *Maintenance:* 2 mg/kg to 4 mg/kg twice daily.

**Children ages 4 to 17 weighing 11 kg (24.2 lb) to less than 30 kg (66 lb).** 1 mg/kg twice daily, increased by 1 mg/kg twice daily every week to recommended maintenance dose. *Maintenance:* 3 mg/kg to 6 mg/kg twice daily.

## **I.V. INFUSION**

**Adults and adolescents age 17 and over.** *Initial:* 100 mg infused over 30 to 60 min twice daily for 1 wk. Dosage increased by 50 mg/day at weekly intervals. Alternatively, 200 mg given as single loading dose infused over 30 to 60 min, followed 12 hr later by 100 mg infused over 30 to 60 min twice daily for 1 wk. Dosage increased at weekly intervals by 50 mg twice daily, as needed, up to recommended maintenance dose. *Maintenance:* 300 to 400 mg daily.

➤ *As adjunct to treat partial-onset seizures*

## **ORAL SOLUTION, TABLETS**

**Adults and adolescents age 17 and over.** *Initial:* 50 mg twice daily, increased by 50 mg twice daily at weekly intervals based on response and tolerance. Alternatively, 200 mg given as single loading dose, followed 12 hr later by 100 mg twice daily for 1 wk. Dosage increased at weekly intervals by 50 mg twice daily, as needed, up to

recommended maintenance dose. *Maintenance:* 100 to 200 mg twice daily.

**Children ages 4 to 17 weighing 50 kg (110 lb) or more.** 50 mg twice daily, increased by 50 mg twice daily every week to recommended maintenance dose.

*Maintenance:* 100 mg to 200 mg twice daily.

**Children ages 4 to 17 weighing 30 kg (66 lb) to less than 50 kg (110 lb).** 1 mg/kg twice daily, increased by 1 mg/kg twice daily every week to recommended maintenance dose. *Maintenance:* 2 mg/kg to 4 mg/kg twice daily.

**Children ages 4 to 17 weighing 11 kg (24.2 lb) to less than 30 kg (66 lb).** 1 mg/kg twice daily, increased by 1 mg/kg twice daily every week to recommended maintenance dose. *Maintenance:* 3 mg/kg to 6 mg/kg twice daily.

## **I.V. INFUSION**

**Adults and adolescents age 17 and over.** *Initial:* 100 mg infused over 30 to 60 min twice daily, increased by 50 mg twice daily, at weekly intervals based on response and tolerance. Alternatively, 200 mg given as a single loading dose infused over 30 to 60 min, followed 12 hr later by 100 mg twice daily infused over 30 to 60 min for 1 wk. Dosage increased at weekly intervals by 50 mg twice daily, as needed, up to recommended maintenance dose.

*Maintenance:* 100 to 200 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients with mild to moderate hepatic impairment or severe renal impairment (creatinine clearance less than 30 ml/min) including end-stage renal disease, dosage reduced by 25% of maximum dosage recommended. Following a 4-hr hemodialysis treatment, dosage supplementation of up to 50% may be required. For patients with hepatic or renal impairment taking strong

CYP2C9 or CYP3A4 inhibitors concurrently, dosage may need to be reduced.

## **Mechanism of Action**

May selectively inactivate voltage-gated sodium channels, which prevents seizure activity by inhibiting repetitive neuronal firing in the brain and stabilizing hyperexcitable neuronal membranes.

## **Contraindications**

Hypersensitivity to lacosamide and its components

## **Interactions**

### **DRUGS**

*beta blockers, calcium channel blockers, potassium channel blockers, sodium channel blockers including those that prolong PR interval such as sodium channel blocking antiepileptic drugs:* Increased risk of AV block, bradycardia, or ventricular tachyarrhythmias  
*strong CYP2C9 inhibitors or CYP3A4 inhibitors (in presence of hepatic or renal impairment):* Possibly significant increase in lacosamide exposure and adverse effects

## **Adverse Reactions**

**CNS:** Aggression, agitation, asthenia, ataxia, attention deficit, cerebellar syndrome, confusion, depression, dizziness, feeling drunk, fever, hallucinations, headache, hypoesthesia, impaired balance, insomnia, irritability, memory impairment, mood alteration, paresthesia,

psychotic disorder, **seizures** (new or worsening),  
somnolence, **suicidal ideation**, tremor, vertigo

**CV: Atrial fibrillation or flutter, AV block, bradycardia, conduction disturbances**, palpitations, prolonged PR interval, **prolonged QT interval**

**EENT:** Blurred vision, diplopia, dry mouth, nystagmus, oral hypoesthesia, tinnitus

**GI:** Constipation, diarrhea, dyspepsia, nausea, vomiting

**HEME: Agranuloctyosis**, anemia, **neutropenia**

**MS:** Dysarthria, muscle spasms

**SKIN:** Pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other: Angioedema; delayed multiorgan hypersensitivity reaction**; injection-site erythema, irritation, and pain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug may cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with concomitant drug therapy with drugs that prolong the PR interval, conduction problems (such as AV block, sick sinus syndrome and no pacemaker in place), severe cardiac disease (such as heart failure, myocardial ischemia), or sodium channel disorders such as Brugada syndrome, because lacosamide may affect conduction. For these patients, ensure an ECG has been done, as ordered, prior to starting therapy and after dosage titration.
- Use cautiously in patients with cardiovascular disease or diabetic neuropathy because drug may predispose them to atrial fibrillation or flutter.
- Know that in patients who are already taking a single antiepileptic and being converted to lacosamide monotherapy, the maintenance dose of lacosamide should be maintained for at least 3 days before beginning the withdrawal of the concomitant antiepileptic drug, as ordered. A gradual withdrawal of the concomitant antiepileptic drug over at least 6 weeks is recommended.
- Administer drug intravenously without further dilution or know that it may be mixed with diluents such as 0.9% sodium chloride injection, 5% dextrose injection, or lactated Ringer's injection. If diluted, do not store diluted solution for more than 4 hours at room temperature.
- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times and lead to suicidal ideation.
- Be aware that lacosamide therapy should be discontinued gradually over at least 1 week to minimize seizure frequency.
- Monitor patient closely for hypersensitivity reactions to lacosamide, such as pruritus, rash, and more than one organ abnormality, such as elevated liver enzymes and myocarditis or pancreatitis. Be aware that drug reaction with eosinophilia and systemic symptoms (DRESS) has occurred with use of other antiepileptics and therefore may possibly occur with lacosamide use. Monitor patient closely and if signs and symptoms are present to suggest DRESS, notify prescriber immediately and expect that drug may be discontinued.

## **PATIENT TEACHING**

- Tell patient that lacosamide tablet or oral solution may be taken with or without food. If using tablet form, instruct patient to swallow tablet whole with liquid and not cut or divide the tablets. If using oral solution, remind patient to measure and administer the dose using a calibrated measuring device because a household teaspoon or tablespoon may not deliver

correct dose. The solution should be discarded if any remains after seven weeks of first opening the bottle.

- Alert patient that the oral solution of lacosamide contains aspartame, a source of phenylalanine that could be harmful to patients with phenylketonuria (PKU).
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms to prescriber immediately. If allergic reaction occurs, counsel patient to seek immediate emergency medical care.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Encourage patient to carry medical identification that indicates her diagnosis and drug therapy.
- Tell women of childbearing age to notify prescriber if pregnancy is suspected or occurs. If pregnancy is confirmed, encourage patient to enroll in the North American Antiepileptic Drug pregnancy registry.

## **lactulose**

**Cholac, Constilac, Constulose,  
Enulose, Generlac, Kristalose**

### **Class and Category**

*Pharmacologic class:* Disaccharide

*Therapeutic:* Colonic acidifier

### **Indications and Dosages**

➤ *To treat constipation*

## POWDER, ORAL SOLUTION

**Adults.** *Initial:* 10 to 20 g daily, increased as needed.  
*Maximum:* 40 g daily.

- *To prevent and treat portal-systemic (hepatic) encephalopathy*

## POWDER, ORAL SOLUTION

**Adults.** *Initial:* 20 to 30 g three times daily or four times daily with dosage adjustment made every day or two, as needed, until two or three soft stools occur daily. *Usual:* 60 to 100 g daily in divided doses. *Rapid laxation:* 20 to 30 g every hr initially and then reduced to usual dosage.

## RETENTION ENEMA

**Adults.** 200 g (300 ml) diluted in 700 ml water or normal saline solution and retained for 30 to 60 min. If evacuated too promptly, repeated immediately. Dosage given every 4 to 6 hr, as needed.

- *To prevent hepatic encephalopathy*

## ORAL SOLUTION

**Children age 1 and older.** 26.7 g (40 ml) to 60 g (90 ml) daily in divided doses with dosage adjusted every day or two, as needed, to produce 2 to 3 soft stools daily.

**Infants up to 1 year.** 1.7 (2.5 ml) to 6.5 g (10 ml) daily in divided doses with dosage adjusted every day or two, as needed, to produce 2 to 3 soft stools daily.

Route	Onset	Peak	Duration
P.O.	24-48 hr	Unknown	Unknown
P.R.	Unknown	Unknown	Unknown

# Mechanism of Action

Arrives unchanged in the colon, where it breaks down into lactic acid and small amounts of acetic and formic acids, acidifying fecal contents. Acidification leads to increased osmotic pressure in the colon, which, in turn, increases stool water content and softens stool.

Also, lactulose makes intestinal contents more acidic than blood. This prevents ammonia diffusion from intestine into blood, as occurs in hepatic encephalopathy. The trapped ammonia is converted into ammonia ions and, by lactulose's cathartic effect, is expelled in feces with other nitrogenous wastes.

# Contraindications

Hypersensitivity to lactulose or its components, low-galactose diet

# Interactions

## DRUGS

*antacids (nonabsorbable), antibiotics (especially oral neomycin)* Decreased effectiveness of lactulose  
*other laxatives:* Possibly falsely indicating adequate lactulose dosage when used to treat hepatic encephalopathy

# Adverse Reactions

**ENDO:** Hyperglycemia

**GI:** Abdominal cramps and distention, diarrhea, flatulence

**Other:** **Hypernatremia, hypokalemia** hypovolemia

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- When giving lactulose by retention enema, use a rectal tube with a balloon to help patient retain enema for 30 to 60 minutes. If not retained for at least 30 minutes, repeat dose. Be sure to deflate balloon and remove rectal tube after completing administration.
- Expect to periodically check serum electrolyte levels of debilitated or elderly patient who uses oral drug longer than 6 months.
- Monitor blood ammonia level in patient with hepatic encephalopathy. Also watch for dehydration, hypernatremia, and hypokalemia when giving higher lactulose doses to treat this condition.
- Monitor diabetic patient for hyperglycemia because lactulose contains galactose and lactose.
- Plan to replace fluids if frequent bowel movements cause hypovolemia.

## PATIENT TEACHING

- Advise patient to take lactulose with food or dilute with juice to reduce sweet taste.
- Direct patient not to use other laxatives while taking lactulose.
- Instruct patient to report abdominal distention or severe diarrhea.

- Advise diabetic patient to check blood glucose level often and to report hyperglycemia.
- Instruct patient to increase fluid intake if frequent bowel movements occur.
- Teach patient with chronic constipation the importance of exercising, increasing fiber in diet, and increasing fluid intake.
- Inform patient that because oral lactulose must reach the colon to work, bowel movement may not occur for 24 to 48 hours after taking drug.

## lamivudine

### 3TC (CAN), Epivir, Epivir-HBV

## Class and Category

*Pharmacologic class:* Synthetic nucleoside analogue

*Therapeutic class:* Antiviral

## Indications and Dosages

- *To treat chronic hepatitis B virus (HBV) infection associated with active liver inflammation and evidence of hepatitis B viral replication*

### ORAL SOLUTION, TABLETS (EPIVIR-HBV)

**Adults.** 100 mg once daily.

**Children ages 2 to 17.** 3 mg/kg once daily. *Maximum:* 100 mg once daily.

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection*

## **ORAL SOLUTION, TABLETS (EPIVIR)**

**Adults.** 300 mg once daily or 150 mg twice daily.

### **TABLETS**

**Children weighing 25 kg (55 lb) or more.** 300 mg once daily or 150 mg in am and 150 mg in pm. *Maximum:* 300 mg daily.

**Children weighing 20 kg (44 lb) to less than 25 kg (55 lb).** 225 mg once daily or 75 mg in am and 150 mg in pm. *Maximum:* 225 mg daily.

**Children and infants ages 3 months and over weighing 14 kg (30.8 lb) to less than 20 kg (44 lb).** 150 mg once daily or 75 mg in am and 75 mg in pm. *Maximum:* 150 mg daily.

### **ORAL SOLUTION**

**Children and infants ages 3 months and over.** 10 mg/kg once daily or 5 mg/kg twice daily. *Maximum:* 300 mg daily.

**DOSAGE ADJUSTMENT** For adults receiving Epivir-HBV, dosage adjustment is as follows: Adults with creatinine clearance between 30 and 49 ml/min, 100 mg first dose, then reduced to 50 mg once daily thereafter. For adults with creatinine clearance between 15 and 29 ml/min, 100 mg first dose, then reduced to 25 mg once daily thereafter. For adults with creatinine clearance between 5 and 14 ml/min, first dose reduced to 35 mg, then reduced to 15 mg once daily thereafter. For adults with creatinine clearance less than 5 ml/min, first dose reduced to 35 mg, then reduced to 10 mg once daily thereafter. There is no recommendation for pediatric patients with renal impairment for Epivir-HBV. For adults receiving Epivir, dosage adjustment is as follows: Adults with creatinine clearance between 30 and

49 ml/min, dosage reduced to 150 mg once daily. For adults with creatinine clearance between 15 and 29 ml/min, 150 mg first dose, then reduced to 100 mg once daily thereafter. For adults with creatinine clearance between 5 and 14 ml/min, 150 mg first dose, then reduced to 50 mg once daily thereafter. For adults with creatinine clearance less than 5 ml/min, 50 mg first dose, then reduced to 25 mg once daily. For pediatric patients with renal impairment taking Epivir, dosage may be reduced or dosing interval increased.

## **Mechanism of Action**

After being phosphorylated to its active metabolite, lamivudine inhibits the DNA- and RNA-dependent polymerase activities of HBV and HIV-1 reverse transcriptases via DNA chain termination after incorporation of the nucleotide analogue into viral DNA. This destroys the activity of the hepatitis B and HIV-1 viruses.

## **Contraindications**

Hypersensitivity to lamivudine or its components

## **Interactions**

### **DRUGS**

*drugs inhibiting organic cation transporters such as trimethoprim:* Possibly altered excretion of lamivudine  
*sorbitol:* Reduced lamivudine exposure and effectiveness

## **Adverse Reactions**

**CNS:** Chills, depression, dizziness, fatigue, fever, headache, insomnia, malaise, neuropathy, paresthesia, peripheral neuropathy, sleep disorders, weakness

**EENT:** Ear, nose, throat infections; nasal congestion or discharge; sore throat; stomatitis

**ENDO:** Cushingoid appearance, fat redistribution, hyperglycemia

**GI:** Abdominal pain, anorexia, bilirubin increase, diarrhea, dyspepsia, elevated lipase and liver enzyme levels,

**exacerbation of hepatitis posttreatment, hepatic decompensation in patient co-infected with HIV-1 and hepatitis C, hepatomegaly with steatosis,** nausea, **pancreatitis,** vomiting

**HEME:** Anemia, **severe anemias including pure red cell aplasia and neutropenia,** splenomegaly, **thrombocytopenia**

**MS:** Abdominal cramps, arthralgia, elevated CPK level, musculoskeletal pain, myalgia, **rhabdomyolysis**

**RESP:** Abnormal breath sounds, cough, wheezing

**SKIN:** Alopecia, pruritus, rash, urticaria

**Other:** **Anaphylaxis, emergence of resistant HBV infection or HIV-1 infection,** immune reconstitution syndrome, **lactic acidosis,** lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.
- Mothers who are not HIV-1 positive should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that Epivir-HBV oral solution and tablets contain a lower dose of lamivudine than used to treat HIV-1 infection and should not be used to treat patients co-infected with HBV and HIV-1 infections. Patients with unrecognized or untreated HIV infection exposed to Epivir-HBV may develop a rapid emergence of HIV-1 resistance. Make sure appropriate HIV counseling and testing have been done before treatment and periodically during treatment with lamivudine to ensure this does not happen.
- Use extreme caution when administering lamivudine to patient with known risk factors for liver disease.
- Monitor patient throughout treatment for evidence of loss of therapeutic response. Indicators include increasing levels of HBV DNA over time after an initial decline below assay limit, progression of clinical signs or symptoms of hepatic disease and/or worsening of hepatic necroinflammatory findings, or return of persistently elevated ALT levels. These findings may require drug to be discontinued.
- Be aware that a switch to an alternative regimen may be needed for patients in whom serum HBV DNA remains detectable after 24 weeks of treatment to reduce the risk of resistance in patients receiving monotherapy with Epivir-HBV.

**WARNING** Know that lactic acidosis and severe hepatomegaly with steatosis have occurred with lamivudine therapy, and death has occurred in some patients. Risk factors include presence of obesity, prolonged nucleoside exposure, and being a woman. However, know that lactic acidosis and severe hepatomegaly with steatosis have also occurred in patients with no known risk

factors. Expect lamivudine to be discontinued in any patient who develops clinical or laboratory findings suggestive of lactic acidosis or pronounced hepatotoxicity, even in the absence of marked transaminase elevations.

- Monitor patient's ALT and HBV DNA levels during treatment to determine treatment options if viral mutants emerge.
- Monitor patients co-infected with HIV-1 and hepatitis C closely for signs and symptoms of liver dysfunction, because hepatic decompensations, some of which resulted in death, have occurred in patients receiving combination antiretroviral therapy for HIV-1 that included interferon alfa.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including lamivudine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Observe patient for redistribution of body fat, including breast enlargement, central obesity, development of buffalo hump, facial wasting, and peripheral wasting, which may produce a cushingoid-type appearance.
- Expect patient to be closely monitored for at least several months after lamivudine has been discontinued, because exacerbation of hepatitis may occur.

## PATIENT TEACHING

- Instruct patient to take lamivudine once daily. If he misses a dose, tell him to take it as soon as he remembers but not to double the next dose or take more than the prescribed dose.
- Advise patient that treatment with lamivudine does not reduce the risk of transmission of HBV or HIV to others through blood contamination or sexual contact.
- Inform diabetic patient using oral solution that each 2-ml dose contains 4 g of sucrose.

- Tell patient being treated for hepatitis B to report immediately any new or worsening symptoms to prescriber, because emergence of resistant hepatitis B virus may occur or disease may worsen during treatment.
- Instruct patient with hepatitis B on the importance of testing for HIV before therapy begins and then periodically throughout therapy to avoid development of resistance to HIV treatment.
- Warn patient with hepatitis B that acute severe exacerbations of hepatitis B may occur following discontinuation of lamivudine. He should not discontinue drug without prescriber knowledge. Tell patient to report any reappearance of signs and symptoms of hepatitis B.
- Warn patient that fat distribution may occur with lamivudine therapy and may alter his appearance.
- Tell women of childbearing age to report a known or suspected pregnancy.

**WARNING** Alert patient that severe conditions may develop while taking lamivudine. Encourage him to stop taking drug and seek medical attention immediately if he experiences any persistent, severe, or unusual symptoms.

## lamotrigine

**Lamictal, Lamictal CD, Lamictal ODT, Lamictal XR**

### **Class and Category**

*Pharmacologic class:* Phenyltriazine

*Therapeutic class:* Anticonvulsant

### **Indications and Dosages**

- *As adjunct to treat partial seizures; to treat generalized seizures of Lennox-Gastaut syndrome; to treat primary generalized tonic-clonic seizures*

## **CHEWABLE TABLETS, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults and children over age 12 taking valproate.** 25 mg every other day for 2 wk, followed by 25 mg once daily for 2 wk. Increased by 25 to 50 mg every 1 to 2 wk, if needed. *Maintenance:* 100 to 200 mg daily.

**Children ages 2 to 12 taking valproate.** 0.15 mg/kg daily as a single dose or in divided doses twice daily for 2 wk and then 0.3 mg/kg daily as single dose or in divided doses twice daily for next 2 wk. Increased by 0.3 mg/kg daily every 1 to 2 wk, if needed, to reach maintenance dosage. *Maintenance:* 1 to 3 mg/kg daily as single dose or in divided doses twice daily. *Maximum:* 200 mg daily.

**Adults and children over age 12 not taking carbamazepine, phenobarbital, phenytoin, primidone, or valproate.** 25 mg once daily for 2 wk, followed by 50 mg once daily for 2 wk. Increased by 50 mg every 1 to 2 wk, if needed. *Maintenance:* 225 to 375 mg daily in 2 divided doses.

**Children ages 2 to 12 not taking carbamazepine, phenobarbital, phenytoin, primidone, or valproate.** 0.3 mg/kg daily in 1 or 2 divided doses for 2 wk; followed by 0.6 mg/kg daily in 2 divided doses for 2 wk. Increased by 0.6 mg/kg daily every 1 to 2 wk, if needed. *Maintenance:* 4.5 to 7.5 mg/kg daily in 2 divided doses. *Maximum:* 300 mg daily.

**Adults and children over age 12 taking carbamazepine, phenobarbital, phenytoin, or primidone but NOT valproate.** 50 mg once daily for 2 wk and then 100 mg daily in 2 divided doses for 2 wk.

Increased by 100 mg daily every 1 to 2 wk, if needed.

*Maintenance:* 300 to 500 mg daily in 2 divided doses

**Children ages 2 to 12 taking carbamazepine, phenobarbital, phenytoin, or primidone but NOT valproate.** 0.6 mg/kg daily in 2 divided doses for 2 wk and then 1.2 mg/kg daily in 2 divided doses for 2 wk. Increased by 1.2 mg/kg every 1 to 2 wk, if needed to reach maintenance dosage. *Maintenance:* 5 to 15 mg/kg daily in 2 divided doses. *Maximum:* 400 mg daily in 2 divided doses. **DOSAGE ADJUSTMENT** For children ages 2 to 12 weighing less than 30 kg (66 lb), maintenance dosage, regardless of what drugs are or are not taken adjunctively, may need to be increased by 50%, based on clinical response.

- *To treat partial seizures as monotherapy with conversion from carbamazepine, phenobarbital, phenytoin, primidone, or valproate*

## **CHEWABLE TABLETS, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults and adolescents age 16 and over converting from carbamazepine, phenytoin, phenobarbital, or primidone.** 50 mg once daily for 2 wk, followed by 50 mg twice daily for next 2 wk. Increased by 100 mg daily every 1 to 2 wk (while continuing to take carbamazepine, phenobarbital, phenytoin, or primidone), until usual maintenance dosage—500 mg daily in 2 divided doses is achieved. Then carbamazepine, phenobarbital, phenytoin, or primidone dosage tapered in 20% decrements weekly over 4 wk and then discontinued.

**Adults and adolescents age 16 and over converting from valproate.** 25 mg every other day for 2 wk followed by 25 mg once daily for 2 wk. Then increased by 25 to 50 mg daily every 1 to 2 wk until maintenance dosage of 200 mg daily is achieved. Then valproate dosage decreased to

500 mg daily by decrements no greater than 500 mg daily every wk and then maintained at 500 mg daily for 1 wk. After valproate dosage has been at 500 mg for 1 wk, lamotrigine dosage increased to 300 mg daily while valproate dosage decreased to 250 mg daily for 1 wk. Then lamotrigine dosage increased by 100 mg daily every wk until maintenance dose of 500 mg daily is reached (given in 2 divided doses). Valproate therapy is then discontinued.

## **E.R. TABLETS**

**Adults and adolescents age 13 and over converting from carbamazepine, phenobarbital, phenytoin, or primidone.** 50 mg once daily for first 2 wk, then increased as follows: 100 mg once daily for wk 3 and 4, then 200 mg once daily for wk 5, then 300 mg once daily for wk 6, then 400 mg once daily for wk 7, and 500 mg once daily for wk 8. Once maintenance dosage of 500 mg daily has been reached, carbamazepine, phenobarbital, phenytoin, or primidone dosage tapered in 20% decrements weekly over 4 wk and then discontinued. Two weeks after carbamazepine, phenobarbital, phenytoin, or primidone has been discontinued, lamotrigine dosage decreased no faster than 100 mg/day each week until monotherapy maintenance dosage of 250 to 300 mg daily has been reached.

**Adults and adolescents age 13 and over converting from valproate.** 25 mg every other day for 2 wk, then increased as follows: 25 mg once daily for wk 3 and 4, then 50 mg once daily for wk 5, then 100 mg once daily for wk 6, then 150 mg once daily for wk 7, and 200 mg once daily for wk 8, with dosage increased to 250 mg once daily, if needed, for wk 9. Once lamotrigine dosage has reached 150 mg once daily, valproate dosage decreased by decrements no greater than 500 mg/day/wk to 500 mg/day

and then maintained for 1 wk, followed by dosage decrease to 250 mg/day for 1 wk and then discontinued.

- *To treat partial seizures with conversion from a single antiepileptic drug other than carbamazepine, phenobarbital, phenytoin, primidone, or valproate*

## **E.R. TABLETS**

**Adults and adolescents age 13 and over converting from an antiepileptic drug other than carbamazepine, phenobarbital, phenytoin, primidone, or valproate.** 25 mg once daily for 2 wk, followed by 50 mg once daily for next 2 wk. Increased to 100 mg once daily for wk 5, followed by 150 mg once daily for wk 6 and 200 mg once daily for wk 7. Further increased by 100 mg once daily at weekly intervals beginning at week 8 and onward until usual maintenance dosage—300 to 400 mg daily—is reached. Once dosage has reached 250 to 300 mg once daily, antiepileptic drug tapered in 20% decrements weekly over 4 wk and then discontinued.

- *As adjunct to treat primary generalized tonic-clonic seizures and partial-onset seizures*

## **E.R. TABLETS**

**Adults and children age 13 and over taking valproate.** 25 mg every other day for 2 wk, followed by 25 mg once daily for 2 wk, followed by 50 mg once daily for 1 wk. Then 100 mg once daily for 1 wk, then 150 mg once daily. Dosage increased further, as needed, but increase not greater than 100 mg/day on a weekly basis. *Maintenance:* 200 to 250 mg once daily.

**Adults and children age 13 and over NOT taking carbamazepine, phenobarbital, phenytoin, primidone, or valproate.** 25 mg once daily for 2 wk, followed by 50 mg once daily for 2 wk, followed by 100 mg once daily for 1

wk. Then 150 mg once daily for 1 wk, followed by 200 mg once daily. Dosage increased further, as needed, but increase not greater than 100 mg/daily on a weekly basis.

*Maintenance:* 300 to 400 mg once daily.

**Adults and children age 13 and over taking carbamazepine, phenobarbital, phenytoin, or primidone and NOT taking valproate.** 50 mg once daily for 2 wk, followed by 100 mg once daily for 2 wk, followed by 200 mg once daily for 1 wk. Then, 300 mg once daily for 1 wk, followed by 400 mg once daily. Dosage increased further, as needed, but increase not greater than 100 mg/daily on a weekly basis. *Maintenance:* 400 to 600 mg once daily.

- *As maintenance therapy for bipolar 1 disorder to delay occurrence of mood episodes (depression, mania, hypomania, mixed episodes) in patients being treated for acute mood episodes with standard therapy*

## **CHEWABLE TABLETS, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults not taking carbamazepine, phenobarbital, phenytoin, primidone, rifampin, or valproate.** 25 mg once daily for 2 wk, followed by 50 mg once daily for 2 wk, followed by 100 mg once daily for 1 wk, and then increased to 200 mg once daily as maintenance dose. *Maximum:* 200 mg daily.

**Adults taking valproate.** 25 mg every other day for 2 wk, followed by 25 mg once daily for 2 wk, followed by 50 mg once daily for 1 wk, and then increased to 100 mg once daily as maintenance dose.

**Adults taking carbamazepine, lopinavir/ritonavir, phenobarbital, phenytoin, primidone, or rifampin, but not valproate.** 50 mg once daily for 2 wk, followed by 100 mg once daily in divided doses for 2 wk, followed by 200

mg once daily in divided doses for 1 wk, then increased to 300 mg daily in divided doses for 1 wk, and then increased to 400 mg daily in divided doses as maintenance dose.

**DOSAGE ADJUSTMENT** *For all indications:* For women taking estrogen-containing oral contraceptives and NOT taking carbamazepine, phenobarbital, phenytoin, primidone, or other drugs such as rifampin and protease inhibitors such as atazanavir/ritonavir or lopinavir/ritonavir, maintenance dose may need to be increased gradually by as much as twofold over recommended target maintenance dose. For women discontinuing estrogen-containing oral contraceptives who have been stabilized on lamotrigine prior to discontinuation and NOT taking carbamazepine, phenobarbital, phenytoin, primidone, or other drugs such as rifampin and protease inhibitors such as atazanavir/ritonavir or lopinavir/ritonavir, maintenance dose may need to be decreased gradually by as much as half. For patient with moderate to severe hepatic impairment without ascites, all dosages decreased by 25%, and for patient with severe hepatic impairment with ascites, all dosages decreased by 50%. For patient with significant renal impairment, maintenance dosage may need to be reduced on individual basis. Dosage may need to be increased during pregnancy.

Route	Onset	Peak	Duration
P.O.	Days to weeks	Unknown	Unknown

## Mechanism of Action

May stabilize neuron membranes by blocking their sodium channels and inhibiting release of excitatory neurotransmitters, such as aspartate and glutamate through these channels. By blocking the release of neurotransmitters, lamotrigine inhibits the spread of

seizure activity in the brain, reduces seizure frequency and diminishes mood swings.

## Contraindications

Hypersensitivity to lamotrigine or its components

## Interactions

### DRUGS

*atazanavir/ritonavir, carbamazepine, lopinavir/ritonavir, phenobarbital, phenytoin, primidone, rifampin*: Decreased blood lamotrigine level

*estrogen-containing oral contraceptive preparations containing 30 mcg ethinylestradiol and 150 mcg*

*levonorgestrel*: Decreased blood levels of both drugs

*organic cationic transporter 2 (OCT2) substrates such as*

*dofetilide*: Possibly increased plasma levels of these drugs

*valproic acid*: Increased lamotrigine level

## Adverse Reactions

**CNS:** Aggression, amnesia, anxiety, **aseptic meningitis**, ataxia, confusion, depression, dizziness, drowsiness, emotional lability, exacerbation of parkinsonian symptoms, fever, headache, **increased seizure activity**, lack of coordination, **suicidal ideation**, tics

**CV:** Chest pain, vasculitis

**EENT:** Blurred vision, diplopia, dry mouth, nystagmus

**GI:** Abdominal pain, anorexia, constipation, diarrhea, esophagitis, **hepatic failure**, **pancreatitis**, vomiting

**HEME:** **Agranulocytosis**, anemia, **aplastic or hemolytic anemia**, **disseminated intravascular coagulation (DIC)**, eosinophilia, **hemophagocytic**

**lymphohistiocytosis, leukopenia, neutropenia, pancytopenia, severe anemia such as pure red cell aplasia, thrombocytopenia**

**MS: Rhabdomyolysis**

**RESP: Apnea**

**SKIN: Petechiae**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other: Angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms, hypogammaglobulinemia lupus-like reaction, lymphadenopathy, progressive immunosuppression

## **Childbearing Considerations**

### **PREGNANCY**

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Dosage may need to be adjusted during pregnancy.

### **LACTATION**

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## **Nursing Considerations**

- Use cautiously in patients with illnesses that could affect elimination or metabolism of lamotrigine, such as cardiac hepatic, or renal functional impairment.

- Be aware that the patient may be converted directly from immediate-release lamotrigine to extended-release lamotrigine with the initial dose of extended-release matching the total daily dose of immediate-release lamotrigine. However, monitor effects closely, especially for patient who is receiving an enzyme-inducing agent that may lower plasma levels of lamotrigine on conversion. If drug effectiveness appears to be altered, notify prescriber and expect a dosage adjustment.

**WARNING** Be aware that lamotrigine may cause potentially life-threatening rash. Notify prescriber at first sign, and expect to discontinue drug. Lamotrigine therapy shouldn't be restarted after rash subsides.

- Monitor patient for adverse reactions, especially suicidal thoughts, at start of therapy and with each dosage increase.

**WARNING** Monitor patient for hypersensitivity, such as fever, rash, or lymphadenopathy in association with other organ system dysfunction that may be suggestive of DRESS. Although rare, DRESS may be life-threatening. If suspected, notify prescriber immediately and expect lamotrigine to be discontinued.

**WARNING** Monitor patient closely for signs and symptoms of aseptic meningitis such as fever, headache, nausea, nuchal rigidity, or vomiting. Additional signs and symptoms may include altered consciousness, chills, myalgia, photophobia, rash, and somnolence. These symptoms may occur within 1 day to 1.5 months following the initiation of lamotrigine therapy. Notify prescriber immediately, if suspected, and expect drug to be discontinued.

- Monitor patient for seizure activity during lamotrigine therapy.

**WARNING** Monitor patient closely for signs and symptoms of hemophagocytic lymphohistiocytosis such as coagulation abnormalities, cytopenias, fever,

hepatosplenomegaly, liver dysfunction, lymphadenopathy, neurologic symptoms, and rash that may occur within 8 to 24 days from start of lamotrigine therapy. Be aware that this is a life-threatening condition of extreme systemic inflammation.

- Expect to taper dosage over at least 2 weeks, even for treatment of bipolar disorder to avoid stopping lamotrigine abruptly, which may increase seizure activity.

## **PATIENT TEACHING**

- Advise patient to take lamotrigine exactly as prescribed and not to stop abruptly because seizure activity may increase.
- Instruct patient to seek immediate emergency help or call local poison control center if too much lamotrigine is taken.
- Advise patient to notify prescriber immediately if rash or other symptoms of hypersensitivity, such as a fever or swollen glands, occur.
- Instruct patient to report increased seizure activity, vision changes, and vomiting.

**WARNING** Inform patient that excessive immune activation may occur with lamotrigine therapy and to immediately report fever, rash, or swollen lymph nodes.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid direct sunlight and to wear protective clothing to minimize risk of photosensitivity.
- Instruct patient to wear or carry medical identification stating that she takes lamotrigine.
- Caution patient or caregiver about possibility of suicidal thoughts, especially when therapy begins or dosage changes.

**WARNING** Advise patient to notify prescriber immediately if she develops any combination of an abnormal

sensitivity to light, chills, confusion, drowsiness fever, headache, myalgia, nausea, rash, stiff neck, or vomiting while taking lamotrigine.

- Tell female patient to notify prescriber if she becomes pregnant, is considering pregnancy, or starts or stops an oral hormonal contraceptive or other female hormonal preparation.
- Urge woman who becomes pregnant while taking lamotrigine to enroll in the North American Antiepileptic Drug Pregnancy Registry by calling 1-888-233-2334. Explain that registry is collecting information about safety of antiepileptic drugs during pregnancy.

## lansoprazole

**Prevacid, Prevacid-24 Hour, Prevacid I.V., Prevacid SoluTab**

## dexlansoprazole

**Dexilant, Dexilant SoluTab**

### Class and Category

*Pharmacologic class:* Proton pump inhibitor

*Therapeutic class:* Antiulcer

### Indications and Dosages

- *To treat duodenal ulcers and maintain healed duodenal ulcers*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** 15 mg daily before a meal for 4 wk. *Maintenance:* 15 mg daily.

- *To treat benign gastric ulcers*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** 30 mg daily before a meal for up to 8 wk.

- *To treat NSAID-associated gastric ulcer and risk reduction for NSAID-associated gastric ulcer in patients who need to continue NSAID therapy*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** 30 mg daily before a meal for 8 wk. *Risk reduction:* 15 mg daily with a meal for up to 12 wk.

- *To treat symptomatic gastroesophageal reflux disease (GERD)*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** 15 mg daily before a meal for up to 8 wk.

- *To treat symptomatic nonerosive gastroesophageal reflux disease*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS (DEXLANSOPRAZOLE)**

**Adults and children ages 12 and over.** 30 mg once daily for 4 wk.

- *To heal all grades of erosive esophagitis*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS (DEXLANSOPRAZOLE)**

**Adults and children ages 12 and over.** 60 mg once daily for up to 8 wk.

- *To maintain healed erosive esophagitis*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS (DEXLANSOPRAZOLE)**

**Adults and children ages 12 and over.** 30 mg once daily.

- *To treat erosive esophagitis; to maintain healed erosive esophagitis*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** *Initial:* 30 mg daily before a meal for up to 8 wk. Continued another 8 wk if indicated. *Maintenance:* 15 mg daily.

- *To treat erosive esophagitis short-term (up to 7 days) in patients unable to take oral medication*

## **I.V. INFUSION**

**Adults.** 30 mg daily infused over 30 min for up to 7 days.

- *To treat pathological hypersecretory conditions, such as Zollinger-Ellison syndrome*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** *Initial:* 60 mg daily before a meal, increased as needed according to patient's condition. Doses exceeding 120 mg/day administered in divided doses.

- *To eradicate Helicobacter pylori to reduce risk of duodenal ulcer recurrence*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Adults.** 30 mg plus 1 g amoxicillin and 500 mg clarithromycin every 12 hr before meals for 10 to 14 days. Or, 30 mg plus 1 g amoxicillin three times daily before meals for 14 days.

- *To treat symptomatic pediatric gastroesophageal reflux disease*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Children ages 12 to 17.** 15 mg daily before a meal for up to 8 wk.

**Children ages 1 to 11 weighing 30 kg (66 lb) or less.** 15 mg daily before a meal for up to 12 wk.

**Children ages 1 to 11 weighing more than 30 kg.** 30 mg daily before a meal for up to 12 wk.

- *To treat symptomatic pediatric erosive esophagitis*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE SUSPENSION, DELAYED-RELEASE ORALLY DISINTEGRATING TABLETS**

**Children ages 12 to 17.** 30 mg daily before a meal for up to 8 wk.

**Children ages 1 to 11 weighing 30 kg (66 lb) or less.** 15 mg daily before a meal for up to 12 wk.

**Children ages 1 to 11 weighing more than 30 kg.** 30 mg daily before a meal for up to 12 wk.

- *To treat frequent heartburn*

## **E.R. CAPSULES (PREVACID 24-HR)**

**Adults.** 15 mg daily for 14 days. May repeat course every 4 months.

***DOSAGE ADJUSTMENT*** For patients with severe hepatic impairment prescribed lansoprazole, dosage not to exceed 15 mg daily regardless of condition being treated. For patients with moderate hepatic impairment prescribed dexlansoprazole for the healing of erosive esophagitis, dosage not to exceed 30 mg once daily.

Route	Onset	Peak	Duration
P.O.	1-3 hr	Unknown	Over 24 hr

## **Mechanism of Action**

Binds to and inactivates the hydrogen-potassium adenosine triphosphate enzyme system (also called the proton pump) in gastric parietal cells. This action blocks the final step of gastric acid production.

# Incompatibilities

Don't give any other drugs with parenteral lansoprazole, and dilute only with solutions recommended by manufacturer (sterile water for initial reconstitution and D<sub>5</sub>W, lactated Ringer's solution, or normal saline solution for further dilution).

# Contraindications

Concurrent therapy with rilpivirine-containing products, hypersensitivity to lansoprazole or its components

# Interactions

## DRUGS

*antiretrovirals such as atazanavir, nelfinavir, rilpivirine:*

Possible decreased antiviral effect and increased risk of drug resistance to antiretroviral

*dasatinib, erlotinib, iron salts, itraconazole, ketoconazole, mycophenolate mofetil, nilotinib, other drugs that depend on low gastric pH for bioavailability:* Inhibited absorption of these drugs.

*digoxin:* Increased digoxin absorption with possible toxicity

*methotrexate:* Possibly elevated methotrexate levels, which may cause toxicity

*rifampin, St. John's wort and other strong CYP2C19 or*

*CYP3A4 inducers:* Decreased plasma levels of dexlansoprazole

*saquinavir:* Possibly increased toxicity of saquinavir

*sucralfate:* Decreased and delayed lansoprazole absorption

*tacrolimus:* Possibly increased blood tacrolimus levels

*theophylline:* Increased clearance of theophylline reducing effectiveness

*voriconazole and other strong CYP2C19 or CYP3A4 inhibitors:* Increased exposure of lansoprazole possibly causing toxicity  
*warfarin:* Increased INR and PT with possibly increased risk of serious bleeding

## Adverse Reactions

**CNS:** **CVA**, dizziness, headache, transient ischemic attack  
**EENT:** Blurred vision, deafness, oral edema oropharyngeal pain, **pharyngeal edema**, **throat tightness**  
**GI:** Abdominal pain, anorexia, **Clostridium difficile-associated diarrhea**, diarrhea, elevated liver enzymes, flatulence, fundic gland polyps, **hepatitis**, **hepatotoxicity**, increased appetite, nausea, **pancreatitis**, vomiting  
**GU:** **Acute renal failure**, interstitial nephritis, urine retention  
**HEME:** **Agranulocytosis**, **aplastic anemia**, decreased hemoglobin, **hemolytic anemia**, **idiopathic thrombocytopenic purpura**, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**, **thrombotic thrombocytopenic purpura**  
**MS:** Arthralgia, bone fracture, bursitis, myositis  
**RESP:** Upper respiratory tract infection  
**SKIN:** Cutaneous lupus erythematosus, **erythema multiforme**, **exfoliative dermatitis**, leucocytoclastic vasculitis, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**  
**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia**, **hypomagnesemia**, **hyponatremia**, injection-site reaction, systemic lupus erythematosus, vitamin B<sub>12</sub> deficiency

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Give lansoprazole before meals. Dexlansoprazole may be taken with or without food. Antacids may be given as well, if needed.
- Keep in mind that if patient is prescribed capsules and has trouble swallowing them, open and sprinkle granules on applesauce, cottage cheese, Ensure pudding, strained pears, or yogurt. Don't crush granules. Have patient swallow mixture immediately. Or, empty granules into 2 ounces apple, orange, or tomato juice; mix quickly, and have patient swallow immediately. Then add 2 or more ounces of juice to glass and have patient drink immediately to ensure full dose.
- For delayed-release orally disintegrating tablets, place tablet on patient's tongue and let it dissolve, with or without water, until patient can swallow particles.
- For patient with nasogastric tube, don't use oral suspension. Instead use capsules or orally disintegrating tablets. For capsule form, open capsule, mix granules in 40 ml apple juice only, and inject through tube. Then flush tube with apple juice only. For disintegrating tablets, place tablet in syringe and draw up 4 ml (for 15-mg tablet) or 8 ml (for 30-mg tablet) of water. Shake gently, and inject through tube within 15 minutes. Then refill syringe with 5 ml of water, shake gently, and inject through tube.
- For delayed-release oral suspension, empty packet contents into a container with 2 tablespoons water (no other liquids or foods), stir well, and have patient drink immediately. If any particles remain in container, add more water, stir, and have patient drink again immediately.

- Reconstitute parenteral form by injecting 5 ml sterile water into 30-mg drug vial. Mix gently until powder dissolves. Use within 1 hour. After reconstitution, dilute with 50 ml D<sub>5</sub>W lactated Ringer's solution, or normal saline solution. Give within 12 hours if mixed with D<sub>5</sub>W or 24 hours if mixed with lactated Ringer's solution or normal saline solution.
- Give parenteral drug with a filter following manufacturer's guidelines. Change filter every 24 hours. Give as I.V. infusion over 30 minutes. Flush line with D<sub>5</sub>W lactated Ringer's solution, or normal saline solution before and after giving lansoprazole.
- Expect to give lansoprazole with antibiotics when used to eradicate *H. pylori* because decreased gastric acid secretion helps antibiotics eradicate *H. pylori*.
- Be aware that diarrhea from *C. difficile* infection can occur with or without concurrent antibiotics when lansoprazole is used. If *C. difficile*-associated diarrhea occurs, notify prescriber and expect to withhold drug and treat with an antibiotic effective against *C. difficile*, *electrolytes*, *fluids*, and *protein*.
- Monitor patient for bone fracture, especially in patients receiving multiple daily doses for more than a year, because proton pump inhibitors, such as lansoprazole, increase risk for osteoporosis-related fractures of the hip, spine, or wrist.
- Monitor the patient, especially the patient on long-term therapy for hypomagnesemia. If patient is to remain on lansoprazole long term, expect to monitor the patient's serum magnesium level, as ordered, and if level becomes low, anticipate that magnesium replacement therapy and lansoprazole will be discontinued.
- Monitor patient for renal dysfunction because drug may cause acute interstitial nephritis at any point during lansoprazole therapy. Expect drug to be discontinued if it occurs.
- Be aware that drug may cause false-positive results in diagnostic investigations for neuroendocrine tumors. Expect drug to be temporarily discontinued for at least 14 days before testing is done. Also know that drug can cause a hyper-response in gastrin secretion in response to secretin stimulation test. Expect lansoprazole to be temporarily withheld at least 30 days before assessment is done. Be aware that false-positive urine screening tests for tetrahydrocannabinol may occur during lansoprazole therapy.
- Monitor patient for cutaneous and systemic lupus erythematosus either as new onset or exacerbation of existing disorder. Know that cutaneous lupus erythematosus occurs more commonly. Expect lansoprazole to be discontinued if present.

- Be aware that long-term use (especially more than one year) of lansoprazole increases risk for the development of fundic gland polyps. Be aware that the drug should be given for the shortest duration possible for the condition being treated.

## **PATIENT TEACHING**

- Urge patient to take lansoprazole exactly as prescribed, usually before a meal to decrease gastric acid output. Tell patient taking dexlansoprazole that drug may be taken with or without food.
- Tell patient who is having trouble swallowing dexlansoprazole capsules to open them and sprinkle granules on 1 tablespoon of applesauce and swallow immediately. If patient has trouble swallowing lansoprazole capsules, tell her to open them and sprinkle granules on applesauce, cottage cheese, Ensure pudding, strained pears, or yogurt and to swallow immediately without chewing. Or, she may empty lansoprazole granules into 2 ounces of apple, orange, or tomato juice, mix quickly, and swallow immediately. Tell her to refill glass with 2 or more ounces of juice and drink immediately to ensure a full dose.
- Tell patient prescribed delayed-release orally disintegrating tablets to place tablet on tongue, let it dissolve, and then swallow particles with or without water. Also tell her not to break, cut, or chew the tablets.
- Tell patient prescribed delayed-release oral suspension to empty contents of packet into a container with 2 tablespoons of water (no other liquids or foods), stir well, and drink immediately. If particles remain in container, she should add water, stir, and drink immediately.
- Inform patient that she may take antacids with lansoprazole. But also tell patient to inform all prescribers of lansoprazole therapy.
- Tell patient to stop taking drug and report to prescriber blood in urine or decrease in urination, joint pain that is new or worsening, or a rash on arms or cheeks that gets worse in the sun.
- Advise patient to report severe headache, or worsening of symptoms immediately to prescriber.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that bloody or watery stools can occur 2 or more months after antibiotic therapy and can be serious, requiring prompt treatment.
- Alert women of childbearing age to notify prescriber if pregnancy is suspected or known.

# lanthanum carbonate

**Fosrenol**

## Class and Category

*Pharmacologic class:* Rare earth element

*Therapeutic class:* Phosphate binder

## Indications and Dosages

- *To reduce serum phosphate levels in patients with end-stage renal disease*

### ORAL POWDER, TABLETS (CHEWABLE)

**Adults.** *Initial:* 500 mg three times daily with meals or immediately after meals; increased, as needed, by 750 mg daily every 2 to 3 wk until acceptable serum phosphate level is reached.

## Contraindications

Bowel obstruction, fecal impaction, hypersensitivity to lanthanum carbonate or any of its components, hypophosphatemia, ileus

## Interactions

### DRUGS

*ACE inhibitors; antibiotics such as ampicillin, fluoroquinolones or tetracyclines; antimalarials; drugs with narrow therapeutic range; statins; thyroid hormones:*  
Possibly reduced bioavailability with these drugs

## Adverse Reactions

**CNS:** Headache

**CV:** **Hypotension**

**EENT:** Rhinitis, tooth injury while chewing tablet

**GI:** Abdominal pain, constipation, diarrhea, dyspepsia, fecal impaction, **GI obstruction or perforation**, ileus, nausea, subileus, vomiting

**GU:** Dialysis graft occlusion

**RESP:** Bronchitis

## Mechanism of Action

During digestion, phosphate is released into the upper GI tract (below left) and absorbed into the bloodstream, increasing serum phosphate levels. In patients with end-stage renal disease, however, inefficient phosphate clearance from the blood leads to abnormally elevated levels.

Lanthanum dissociates in the upper GI tract, releasing ions that attach to unbound phosphate to form an insoluble complex (below right). Unabsorbed into the bloodstream, these altered phosphate molecules can't elevate the patient's serum phosphate level.

**SKIN:** Pruritus, rash, urticaria

**Other:** **Hypercalcemia**, **hypocalcemia**, **hypophosphatemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Drug is not recommended for use during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use lanthanum carbonate cautiously in patients with acute peptic ulcer, bowel obstruction, Crohn's disease, or ulcerative colitis because drug effects are unknown in these patients.

- Monitor the patient's serum phosphate levels, as ordered, especially during dosage adjustment, to determine effectiveness of lanthanum carbonate therapy. Serum phosphate levels should fall below 6 mg/dl.
- Monitor patient closely for signs and symptoms of bowel obstruction, fecal impaction, or ileus, especially the patient with a history of colon cancer, gastrointestinal surgery, or hypomotility disorders, as well as the patient receiving calcium channel blockers. Notify prescriber, if present, because these gastrointestinal adverse effects may become serious enough to require hospitalization or surgery.
- Administer tetracyclines and drugs with a narrow therapeutic range at least 1 hour before or 3 hours after lanthanum administration; quinolone antibiotics at least 1 hour before or 4 hours after lanthanum administration; and levothyroxine at least 2 hours before or 2 hours after lanthanum administration to prevent a reduction in bioavailability.

## PATIENT TEACHING

- Instruct patient to take lanthanum carbonate with or immediately after meals.
- Advise patient to chew each tablet thoroughly before swallowing. If patient has trouble chewing tablets, tell her she may crush them.
- Tell patient to sprinkle the prescribed oral powder form on a small quantity of applesauce or other similar foods and consume immediately.
- Urge patient to take drug exactly as prescribed, and explain that it may take weeks to reach a desired serum phosphate level.
- Advise patient to notify prescriber if she experiences gastrointestinal discomfort that becomes prolonged or severe.

**lefamulin**

**Xenleta**

## Class and Category

*Pharmacologic class: Pleuromutilin derivative*

*Therapeutic class: Antibacterial*

## Indications and Dosages

- *To treat community-acquired bacterial pneumonia caused by *Chlamydophila pneumoniae*, *Haemophilus influenzae*, *Legionella pneumophila*, *Mycoplasma pneumoniae*, *Staphylococcus aureus* (methicillin-susceptible isolates), or *Streptococcus pneumoniae**

### **TABLETS**

**Adults.** 600 mg every 12 hr for 5 days.

### **I.V. INFUSION**

**Adults.** 150 mg infused over 60 min every 12 hr for 5 to 7 days.

***DOSAGE ADJUSTMENT*** For patients with severe hepatic impairment, dosing interval increased to every 24 hours when administering drug intravenously. Oral dosage is not recommended for patients with moderate or severe hepatic impairment.

## Mechanism of Action

Inhibits bacterial protein synthesis through interactions with the A- and P- sites of the peptidyl transferase center (PTC) in the V domain of the 23s rRNA of the 50s subunit.

## Incompatibilities

Do not add any other drug or additives to the lefamulin diluted solution because reactions are unknown.

# Contraindications

Concurrent use with sensitive CYP3A4 substrates that prolong QT interval, such as pimozide; hypersensitivity to lefamulin, other pleuromutilin-class drugs, or their components

# Interactions

## DRUGS

*drugs that prolong QT interval, such as Class IA antiarrhythmics (procainamide, quinidine), Class III antiarrhythmics (amiodarone, sotalol), antipsychotics, erythromycin, moxifloxacin, pimozide, tricyclic antidepressants:* Increased risk of prolonged QT interval and life-threatening arrhythmias  
*moderate and strong CYP3A inducers, P-gp inducers:* Decreased lefamulin concentration and effectiveness  
*moderate and strong CYP3A inhibitors, P-gp inhibitors:* Increased lefamulin concentration and risk of adverse reactions  
*sensitive CYP3A4 substrates (alprazolam, diltiazem, pimozide, verapamil, simvastatin, vardenafil):* Increased risk of cardiac conduction toxicities

# Adverse Reactions

**CNS:** Anxiety, headache, insomnia, somnolence

**CV:** **Atrial fibrillation**, palpitations, **prolonged QT interval**

**EENT:** Oropharyngeal candidiasis

**GI:** Abdominal pain, **Clostridium difficile colitis**, constipation, diarrhea, dyspepsia, elevated liver enzymes, epigastric discomfort, erosive gastritis, nausea, vomiting

**GU:** Urine retention, vulvovaginal candidiasis

**HEME:** Anemia, **thrombocytopenia**

**Other:** Elevated alkaline phosphatase and creatine phosphokinase, **hypersensitivity reactions**, **hypokalemia**, injection-site reactions (pain, phlebitis, reactions)

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-855-5NABRIVA.
- Pregnancy status of females of childbearing age should be verified before drug therapy is initiated.
- Drug may cause fetal harm.
- Drug is not recommended for use during pregnancy and should be discontinued as soon as pregnancy is known.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding mothers should pump and discard breast milk for the duration of treatment with drug and for 2 days after final dose.

### REPRODUCTION

- Females of childbearing age should use effective contraception during treatment with drug and for 2 days after final dose.
- Known or suspected pregnancy should be reported immediately.

## Nursing Considerations

- Know that lefamulin should not be given to patients with known prolongation of the QT interval or ventricular arrhythmias (including

torsades de pointes), or in patients receiving class IA or class III antiarrhythmics or other drugs that prolong the QT interval. Lefamulin should also not be given to patients with hepatic impairment or renal failure (if dialysis is required), because metabolic disturbances associated with these conditions may lead to QT prolongation.

- Expect ECG monitoring in patients who are predisposed to QT prolongation for whom use of lefamulin cannot be avoided.
- For I.V. administration, dilute entire 15-ml lefamulin vial in the 250-ml solution of 10-mM citrate buffered 0.9% sodium chloride for injection supplied with drug before use. Solution should be clear. Do not use the diluent bag in series connections. After drug is diluted, it may be stored for up to 24 hours at room temperature or 48 hours if refrigerated. Infuse over 60 minutes.

**WARNING** Do not exceed the recommended rate of infusion of 60 minutes or increase the concentration of lefamulin because the magnitude of QT prolongation may be increased.

- For oral administration, give tablets to patient at least 1 hour before a meal or 2 hours after a meal with 6 to 8 ounces of water.
- Be aware that patient may be switched to the oral form of lefamulin to complete the treatment.
- Assess patients for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If confirmed, expect to discontinue lefamulin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient with hepatic impairment for adverse reactions throughout lefamulin therapy.

## PATIENT TEACHING

- Instruct patient to take oral form of lefamulin at least 1 hour before a meal or 2 hours after a meal by swallowing tablets whole with 6 to 8 ounces of water. Caution patient not to crush or divide tablets.
- Tell patient that if a dose is missed, he should take it as soon as possible any time up to 8 hours prior to the next scheduled dose. If less than 8

hours remains before the next scheduled dose, he should not take the missed dose, but take drug at the next scheduled dose.

- Urge patient to tell prescriber if diarrhea develops, even 2 months or more after lefamulin therapy ends.
- Inform patient that nausea and vomiting are common adverse reactions.
- Advise patient to tell prescriber of all drugs taken, including over-the-counter drugs and herbal products, because lefamulin can interact with other drugs.
- Inform patient that allergic reactions may occur and that serious allergic reactions require immediate treatment.

**WARNING** Warn patient of risks to the fetus if taken during pregnancy. Tell women of childbearing age that a pregnancy test will be performed before lefamulin therapy is begun. Instruct these women to use effective contraception throughout drug therapy and for 2 days after the last dose.

- Instruct women who are breastfeeding to pump and discard breast milk throughout lefamulin therapy and for 2 days after the last dose.

## leflunomide

**Arava**

### Class and Category

*Pharmacologic class:* Pyrimidine synthesis inhibitor

*Therapeutic class:* Antirheumatic

### Indications and Dosages

- *To treat active rheumatoid arthritis*

## **TABLETS**

**Adults who are at low risk for hepatotoxicity and myelosuppression.** *Loading:* 100 mg daily for 3 days, followed by 20 mg daily. *Maximum:* 20 mg/day.

**Adults at high risk for hepatotoxicity or myelosuppression.** 20 mg daily without a loading dose. *Maximum:* 20 mg/day.

***DOSAGE ADJUSTMENT*** Dosage reduced to 10 mg daily if poorly tolerated.

## **Mechanism of Action**

Inhibits dihydroorotate dehydrogenase, the enzyme in autoimmune process that leads to rheumatoid arthritis. With this action, leflunomide relieves inflammation and prevents alteration of the autoimmune process.

## **Contraindications**

Hypersensitivity to leflunomide, teriflunomide, or their components; pregnancy; severe hepatic impairment

## **Interactions**

### **DRUGS**

*BCRP and organic anion transporting polypeptide B1 and B3 (AOTP1B1) substrates such as HMG-Co reductase inhibitors (atorvastatin, nateglinide, pravastatin, repaglinide, rosuvastatin, simvastatin), methotrexate, mitoxantrone, rifampin:* Elevated blood levels of these drugs

*CYP1A2 substrates such as alosetron, duloxetine, theophylline, tizanidine:* Possibly decreased exposure with decreased effectiveness of these drugs  
*CYP2C8 substrates such as paclitaxel, pioglitazone, repaglinide, rosiglitazone:* Possibly increased levels of these drugs with increased risk of adverse reactions  
*oral contraceptives, organic anion transporter 3 (OAT3) substrates such as cefaclor, cimetidine, ciprofloxacin, furosemide, ketoprofen, methotrexate, penicillin G, zidovudine:* Possibly increased exposure of these drugs with increased risk of adverse reactions  
*rifampin* Increased blood leflunomide level  
*warfarin:* Possibly decreased peak INR by about 25%

## Adverse Reactions

**CNS:** Anxiety, dizziness, drowsiness, fatigue, fever, headache, paresthesia, peripheral neuropathy

**CV:** Chest pain, hypertension, palpitations, tachycardia, vasculitis

**EENT:** Blurred vision, conjunctivitis, dry mouth, epistaxis, mouth ulcers, pharyngitis, rhinitis, sinusitis

**GI:** Abdominal pain, **acute hepatic necrosis**, cholestasis, colitis, constipation, diarrhea, elevated liver enzymes, flatulence, gastritis, gastroenteritis, **hepatic injury or failure, hepatitis**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Hypophosphaturia, UTI

**HEME:** **Agranulocytosis**, anemia, **leukopenia, neutropenia, pancytopenia, thrombocytopenia**

**MS:** Back pain, synovitis, tendinitis

**RESP:** **Asthma**, bronchitis, dyspnea, **interstitial lung disease, pulmonary fibrosis or hypertension**, respiratory tract infection

**SKIN:** Alopecia (transient), cutaneous lupus erythematosus, cutaneous necrotizing vasculitis, **erythema multiforme**, erythematous rash, pruritus, pustular psoriasis, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria, worsening psoriasis  
**Other:** **Angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, opportunistic infections, **sepsis**, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-877-311-8972 or <http://www.pregnancystudies.org/participate-in-a-study/>.
- Drug can cause fetal harm.
- Drug is contraindicated during pregnancy.
- A negative pregnancy test must be obtained before drug therapy is begun.
- If pregnancy occurs, drug must be discontinued immediately and an accelerated drug elimination procedure done in an effort to reduce the risk to the fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should be discontinued during drug therapy.

### REPRODUCTION

- Women of childbearing age need to use an effective contraception during drug therapy and also when drug is discontinued while undergoing the drug elimination procedure until verification that the plasma teriflunomide concentration is less than 0.02 mg/L.

- Women of childbearing age should immediately report suspected or known pregnancy to prescriber.

## Nursing Considerations

- Know that leflunomide isn't recommended for patients with severe immunodeficiency, or severe, uncontrolled infections because of its immunosuppressant effect. It is also not recommended for patients with liver disease or those with a serum alanine aminotransferase level greater than two times the upper level normal prior to initiation of therapy because drug may worsen liver dysfunction.
- Use cautiously in patients who are over 60 years of age, in patients taking concomitant neurotoxic drugs, or in patients with diabetes because of an increased risk of developing peripheral neuropathy. If peripheral neuropathy occurs during leflunomide therapy, notify prescriber and expect drug to be discontinued and possibly cholestyramine washout to be ordered.
- Test patient for latent tuberculosis before starting leflunomide, as ordered. If positive, expect standard medical treatment to be given before leflunomide therapy starts.
- Ensure that women of childbearing age have a negative pregnancy test result prior to starting leflunomide therapy.
- Obtain baseline blood pressure before starting leflunomide, and monitor periodically thereafter because drug may cause hypertension.
- Know that patients at high risk for drug-associated hepatotoxicity are those who are taking concomitant methotrexate. Patients at high risk for drug-associated myelosuppression are those who are taking concomitant immunosuppressants.
- Assess liver enzyme (ALT and AST) levels at start of therapy, monthly during first 6 months, and if stable, every 6 to 8 weeks thereafter, as ordered. If levels become elevated greater than threefold upper level normal, notify prescriber and expect leflunomide therapy to be withheld until underlying cause is determined. If the elevation is thought to be leflunomide induced, expect to start cholestyramine washout, as ordered, and monitor liver test weekly until normalized. If another cause is found for the elevation, expect to resume leflunomide therapy.
- Obtain platelet count, hemoglobin or hematocrit, and WBC count at start of therapy and every 4 to 8 weeks thereafter, as ordered.

- Notify prescriber if patient develops serious infection because drug may need to be interrupted and charcoal or cholestyramine given to eliminate drug rapidly.

**WARNING** Monitor patient's respiratory function closely because drug may cause interstitial lung disease that could become life-threatening. If patient develops a cough and dyspnea, notify prescriber; drug will need to be stopped, and patient may need charcoal or cholestyramine to eliminate drug rapidly.

**WARNING** Assess patient's skin regularly for evidence of serious skin reactions. If present, notify prescriber, as drug will need to be discontinued, and patient may need charcoal or cholestyramine to eliminate drug rapidly.

## PATIENT TEACHING

- Advise patient that leflunomide doesn't cure arthritis but may relieve its symptoms and improve physical function.
- Inform patient that reversible hair loss may occur.
- Caution woman of childbearing potential not to become pregnant while taking drug because of the high risk of birth defects.
- Instruct patient to report signs of hepatotoxicity, such as mouth ulcers, unusual bleeding or bruising, and yellow skin or eyes.
- Tell patient to report signs of respiratory dysfunction, such as cough and dyspnea, and signs of persistent or serious skin reactions.
- Advise patient to avoid live vaccines during leflunomide therapy.
- Instruct patient to notify prescriber if she develops an infection.

**lesinurad**

**Zurampic**

## Class and Category

*Pharmacologic class:* Uric acid transporter 1 inhibitor

*Therapeutic class:* Antigout

## Indications and Dosages

- *Adjunct to treat hyperuricemia associated with gout in patients who have not achieved target serum uric acid levels with a xanthine oxidase inhibitor alone*

### **TABLETS**

**Adults.** 200 mg once daily in the morning with a meal and coadministered with a xanthine oxidase inhibitor such as allopurinol or febuxostat.

## Mechanism of Action

Reduces serum uric acid levels by inhibiting the function of transporter proteins involved in uric acid reabsorption in the kidney. This increases renal clearance and excretion of uric acid, which lowers serum uric acid level in the body.

## Contraindications

Dialysis, end-stage renal disease, hypersensitivity to lesinurad or its components, kidney transplant recipients, Lesch-Nyhan syndrome, severe renal impairment (creatinine clearance less than 30 ml/min), tumor lysis syndrome

# Interactions

## DRUGS

*amlodipine, antihypertensives which are CYP3A substrates, HMG-CoA reductase inhibitors, sildenafil*: Possibly reduced plasma concentrations of these drugs.

*aspirin above 325 mg daily (in combination with allopurinol)*: Possibly decreased effectiveness of lesinurad

*CYP2C9 inducers such as carbamazepine, rifampin*:

Decreased effectiveness of lesinurad

*CYP2C9 inhibitors such as amiodarone, fluconazole*:

Increased lesinurad exposure with increased risk of adverse reactions

*hormonal contraceptives*: Possibly decreased effectiveness of the contraceptive regardless of the form used to administer it

*valproic acid*: Possibly interference with lesinurad metabolism

## Adverse Reactions

**CNS:** CVA, headache

**CV:** MI

**GI:** GI reflux disease

**GU:** Acute or chronic renal failure, elevated serum creatinine level, nephrolithiasis

**Other:** Flu-like symptoms, gout flare

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Be aware that lesinurad should not be given to a patient who is taking less than 300 mg of allopurinol daily or less than 200 mg of allopurinol daily who has an estimated creatinine clearance less than 60 ml/min.
- Know that lesinurad should not be given to patients who have a creatinine clearance less than 45 ml/min.
- Use cautiously in patients who are CYP2C9 poor metabolizers because lesinurad exposure is increased possibly increasing risk of adverse reactions.
- Assess patient's renal function, as ordered, prior to starting lesinurad therapy and periodically thereafter by monitoring serum creatinine levels, as ordered. Know that frequency of monitoring should be increased in patients with a serum creatinine elevation 1.5 to 2 times the pretreatment value or in patients who have a decline in creatinine clearance below 60 ml/min. Expect drug therapy to be interrupted if serum creatinine level becomes elevated above two times the pretreatment value or the patient experiences symptoms that may indicate acute uric acid nephropathy such as flank pain, nausea, or vomiting. Expect drug to be discontinued if creatinine clearance persistently falls below 45 ml/min during treatment or no other explanation is found for serum creatinine abnormalities.
- Expect to withhold lesinurad therapy, as ordered, if the treatment with the prescribed xanthine oxidase inhibitor is interrupted because of an increased risk of serious renal dysfunction.
- Monitor patient for gout flares after lesinurad therapy is begun because of changing serum uric acid levels resulting in the mobilization of urate from tissue deposits. Institute flare prophylaxis, as ordered, when lesinurad therapy begins. If a gout flare occurs during therapy, know that lesinurad is not usually discontinued but the gout flare is managed concurrently.

- Monitor patient closely for adverse cardiovascular reactions because lesinurad therapy has caused serious effects such as myocardial infarctions or strokes.

## **PATIENT TEACHING**

- Instruct patient to take lesinurad with food and water at the same time as his morning dose of prescribed xanthine oxidase inhibitor.
- Stress importance of staying well hydrated by drinking at least 2 liters of fluid daily.
- Tell patient that if for any reason his prescribed xanthine oxidase inhibitor therapy is discontinued, he should consult his prescriber and expect to discontinue taking lesinurad also.
- Teach patient that if he should miss a dose of lesinurad, he should not take it later in the day but wait to take his normal dose the next day. The dose should never be doubled.
- Alert patient that he will need periodic blood tests to monitor his kidney function while taking lesinurad.
- Warn patient that a gout flare up may occur during lesinurad so he should be compliant with taking gout flare prophylaxis medication. If a gout flare should occur, tell him to notify his prescriber but not to stop taking lesinurad.

## **leuprolide acetate**

**Eligard, Lupron, Lupron Depot,  
Lupron Depot-3 Month 11.25 mg,  
Lupron Depot-3 Month 22.5 mg,  
Lupron Depot-4 Month 30 mg,  
Lupron Depot-6 Month 45 mg,  
Lupron Depot-Ped-1 Month, Lupron  
Depot-Ped-3 Month**

## Class and Category

*Pharmacologic class:* Gonadotropin-releasing hormone analogue

*Therapeutic class:* Antineoplastic, gonadotropin inhibitor

## Indications and Dosages

- *To provide palliative treatment of advanced prostate cancer*

### SUBCUTANEOUS INJECTION (ELIGARD)

**Adults.** 7.5 mg/mo, 22.5 mg every 3 mo, 30 mg every 4 mo, or 45 mg every 6 mo.

### SUBCUTANEOUS INJECTION (LUPRON)

**Adults.** 1 mg daily.

### I.M. INJECTION (LUPRON DEPOT, LUPRON DEPOT-3 MONTH, LUPRON DEPOT-4 MONTH, LUPRON DEPOT-6 MONTH)

**Adults.** 7.5 mg/mo, 22.5 mg every 3 mo, 30 mg every 4 mo, or 45 mg every 6 mo.

- *To treat central precocious puberty*

### I.M. INJECTION (LUPRON DEPOT-PED-1 MONTH)

**Children weighing more than 37.5 kg (83 lb).** 15 mg every 4 wk. *Maximum:* 15 mg every 4 wk.

**Children weighing more than 25 kg (55 lb) to 37.5 kg (83 lb).** *Initial:* 11.25 mg every 4 wk. Dosage increased as

needed to next available dose at next monthly injection.

*Maximum:* 15 mg every 4 wk.

**Children weighing 25 kg (55 lb) or less.** *Initial:* 7.5 mg every 4 wk. Dosage increased as needed to next available dose at next monthly injection. *Maximum:* 15 mg every 4 wk.

### **I.M. INJECTION (LUPRON DEPOT-PED-3 MONTH)**

**Children age 2 and over.** 11.25 or 30 mg once every 3 mo (dose not based on weight).

### **SUBCUTANEOUS INJECTION (LEUPROLIDE ACETATE INJECTION)**

**Children.** 50 mcg/kg daily. Dosage increased in increments of 10 mcg/kg daily, as needed.

➤ *To treat endometriosis*

### **I.M. INJECTION (LUPRON DEPOT, LUPRON DEPOT-3 MONTH)**

**Adults.** 3.75 mg every mo for up to 6 mo or 11.25 mg every 3 mo for up to 6 mo. *Maximum:* 22.5 mg total dose.

➤ *As adjunct to treat anemia due to uterine leiomyomas*

### **I.M. INJECTION (LUPRON DEPOT, LUPRON DEPOT-3 MONTH)**

**Adults.** 3.75 mg every mo up to 3 mo or 11.25 mg single dose. *Maximum:* 11.25 mg total dose.

---

Route	Onset	Peak	Duration
I.M., SubQ*	1 wk	Unknown	4-12 wk after therapy
I.M., SubQ†	2-4 wk	After 1-2 mo	60-90 days after therapy

---

- \* Gonadotropin inhibitor.
- † Antiendometrial, antineoplastic.

## Mechanism of Action

After stimulating follicle-stimulating hormone (FSH) and luteinizing hormone (LH), continuous leuprolide therapy suppresses secretion of gonadotropin-releasing hormone, decreasing estradiol and testosterone levels. In children with central precocious puberty, this stops menses and reproductive organ development.

In adult men, continuous suppression decreases testosterone levels and causes pharmacologic castration, which slows the activity of prostatic neoplastic cells. In women with endometriosis or uterine leiomyomas, leuprolide suppresses ovarian function, inactivating endometrial tissues and resulting in amenorrhea.

## Contraindications

*For all forms:* Hypersensitivity to leuprolide, other gonadotropin-releasing hormone analogues, or their components; *For leuprolide acetate for depot:* Breastfeeding, pregnancy, undiagnosed abnormal uterine bleeding

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Aggression, anger, anxiety, **CVA**, depression, dizziness, emotional lability, fatigue, fever, headache, hyperkinesia, insomnia, lethargy, malaise, memory loss, mood changes, nervousness (adult women), paresthesia, paralysis (from spinal fracture), peripheral neuropathy, rigors, **seizures**, somnolence, **suicidal ideation**, syncope, transient ischemic attacks, weakness

**CV:** **Arrhythmias**, **bradycardia**, **deep vein thrombosis**, edema, hypertension, **hypotension**, palpitations, peripheral vascular disorder, **prolonged QT interval**, vasodilation; angina, **MI**, thrombophlebitis (adult men)

**EENT:** Blurred vision, decreased vision, epistaxis, gingivitis, hearing disorder, pharyngitis, rhinitis, sinusitis

**ENDO:** Amenorrhea, androgenic effects in women, breast tenderness or swelling, decreased testicle size, goiter, growth retardation, gynecomastia, hot flashes, hyperglycemia, **pituitary apoplexy**

**GI:** Colitis, constipation in adult men, dyspepsia, dysphagia, gastroenteritis, **hepatic dysfunction**, increased appetite, nausea, vomiting

**GU:** Bladder spasm, cervix disorder, **cervical neoplasm**, decreased libido, decreased penis size, dysmenorrhea and other menstrual disorders, dysuria, endometriosis flare-up, impotence, incontinence, nocturia, **prostate cancer flare-up**, prostate pain, urinary incontinence, uterine bleeding, vaginal discharge in girls, vaginitis

**HEME:** **Leukopenia**, purpura

**MS:** Arthralgia, body pain in children, bone density loss, bone or limb pain, fibromyalgia, joint disorder, myalgia, myopathy, spinal fracture, tenosynovitis

**RESP:** **Asthmatic attack**, dyspnea, **interstitial lung disease**, **pulmonary embolism**

**SKIN:** Alopecia, clamminess, hirsutism, leukoderma, nail disorder, night sweats, photosensitivity, rash, skin hypertrophy, urticaria

**Other:** Aggravation of preexisting tumor; anaphylaxis; elevated uric acid; flu-like symptoms; infection; injection-site abscess, burning, edema, induration, itching, pain, or redness; tumor flare; weight gain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as major fetal abnormalities and increases risk for pregnancy loss.
- Drug is contraindicated in pregnant women and in women who may become pregnant.
- Women of childbearing age should have a negative pregnancy test before starting drug therapy.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated with breastfeeding.

### REPRODUCTION

- Women of childbearing age should use a nonhormonal method of contraception throughout drug therapy.
- Women of childbearing age should notify prescriber immediately if pregnancy occurs.
- Drug may impair male fertility.

## Nursing Considerations

- Use cautiously in patients at risk for prolonged QT interval, such as in the presence of congenital long QT syndrome, congestive heart failure, or frequent electrolyte abnormalities, and in patients taking drugs that may

prolong the QT interval. Know that electrolyte abnormalities should be corrected, as ordered, prior to therapy beginning. Monitor patient's electrocardiogram and electrolytes regularly throughout therapy, as ordered. Notify prescriber of any abnormalities.

- Let drug come to room temperature before using. Reconstitute leuprolide acetate depot suspension with diluent provided by manufacturer. Add diluent to powder for suspension and thoroughly shake vials to disperse particles into a uniform milky suspension. Use within 30 minutes after mixing, and discard any unused portion. If using a prefilled dual-chamber syringe, follow manufacturer's instructions to release diluent into chamber containing powder. Shake gently after diluted to disperse particles evenly in solution. No dilution or reconstitution is needed for leuprolide acetate injection for subcutaneous administration. Rotate injection sites.

**WARNING** Know that leuprolide acetate for injectable suspension (Eligard) is approved only for use in men for palliative treatment of prostate cancer. Use provided syringes and delivery system, and read and follow instructions carefully to ensure proper mixing of product; shaking alone is inadequate to mix it.

**WARNING** Be aware that life-threatening hypersensitivity reactions such as anaphylaxis and asthmatic attacks have occurred with leuprolide therapy. Patients at higher risk for an asthma attack include those with a preexisting history of asthma, drug and environmental allergies, and sinusitis. If present, alert prescriber and provide supportive emergency care, as prescribed. Also monitor patient for possible allergic reaction (erythema and induration) at injection site because leuprolide injections contain benzyl alcohol. Manufacturer recommends that injection be given by physician.

- Be aware that during first weeks of leuprolide therapy, patient being treated for prostate cancer should be monitored for initial worsening of symptoms, such as difficulty urinating, increased bone pain, and paralysis or paresthesia (in patients with vertebral metastasis). Also be aware that, following the first dose of leuprolide depot form used to treat endometriosis, an increase in symptoms may occur during the initial days

of therapy because of a temporary rise in the hormone levels. These symptoms usually abate with time.

- During treatment for prostate cancer, monitor patient's PSA and serum testosterone levels periodically, as ordered, to determine response to leuprolide therapy.
- Monitor patient's blood glucose level, as ordered, because leuprolide therapy may elevate blood glucose levels, leading to a diagnosis of diabetes mellitus, or may adversely affect glycemic control in patients with diabetes.
- Watch patient closely for signs and symptoms of cardiovascular disease because leuprolide therapy increases risk of myocardial infarction, stroke, and sudden cardiac death.
- Expect to stop drug before age 11 in female patients and age 12 in male patients treated for precocious central puberty.
- Monitor bone density test results, as ordered, of women at risk for osteoporosis who are receiving leuprolide because of possible drug-induced estrogen loss, which may result in decreased bone density.
- Be aware that therapeutic doses of leuprolide suppress the pituitary-gonadal system and that normal function doesn't return for 4 to 12 weeks after drug is stopped.

**WARNING** Monitor patient for evidence of pituitary apoplexy, such as altered mental status, and possibly cardiovascular collapse, ophthalmoplegia, sudden headache, visual changes, and vomiting. Although rare, it may occur within 2 weeks of first dose, sometimes within the first hour. Notify prescriber immediately and provide supportive care.

- Institute seizure precautions, especially in patients with a history of central nervous system dysfunction or tumors, cerebrovascular disorders, epilepsy, or history of seizures or in patients who are taking medications that may cause seizures.

## **PATIENT TEACHING**

- Instruct patient who is self-administering leuprolide injection to use syringe provided by manufacturer. If manufacturer's syringe is

unavailable, advise her to use only a 0.5-ml disposable, low-dose, U-100 insulin syringe to ensure accurate dosage. Substitution of syringes is not recommended for leuprolide acetate for injectable suspension.

- Advise women to report monthly menses or breakthrough bleeding to prescriber immediately.
- Instruct female patient of childbearing age to use a nonhormonal form of contraception during leuprolide therapy. Advise her to stop taking drug and notify prescriber at once if she becomes pregnant. Be aware that patient should not breastfeed while receiving leuprolide.
- Inform patient with osteoporosis or at risk for developing it that drug may increase bone density loss.
- Inform parents of child being treated for central precocious puberty that they should expect normal gonadal-pituitary function to return 4 to 12 weeks after therapy ends.
- Advise patient to report symptoms of depression or memory problems.
- Caution patient being treated for prostate cancer that drug may initially worsen such symptoms as bone pain and that it may cause new signs or symptoms to occur during first few weeks of treatment. Also inform women receiving drug for treatment of endometriosis that an increase in symptoms may occur during the initial days of therapy. Reassure these patients that these reactions are transient.
- Instruct patient to report to prescriber any symptoms that are new, prolonged, or worsen.
- Advise patient with diabetes to monitor his blood glucose level closely.

**WARNING** Emphasize importance of seeking immediate emergency care if patient develops symptoms suggestive of a heart attack or stroke, or symptoms of an allergic reaction.

- Inform caregivers to watch for emotional lability such as aggression, anger, crying, depression, impatience, or irritability. Also warn caregivers that although rare, suicidal behaviors and thoughts have occurred during leuprolide therapy. If present, tell caregiver to notify prescriber.
- Review seizure precautions with patient and family or caregiver.

# levalbuterol hydrochloride

**Xopenex,**

# levalbuterol tartrate

**Xopenex HFA**

## Class and Category

*Pharmacologic class:* Beta<sub>2</sub> agonist

*Therapeutic class:* Bronchodilator

## Indications and Dosages

- *To prevent or treat bronchospasm in reversible obstructive airway disease*

### INHALATION AEROSOL (XOPENEX HFA)

**Adults and children age 4 and over.** 45 or 90 mcg (1 or 2 inhalations) every 4 to 6 hr.

### INHALATION SOLUTION (XOPENEX)

**Adults and children age 12 and over.** 0.63 to 1.25 mg three times daily every 6 to 8 hr.

*Maximum:* 1.25 mg three times daily.

**Children ages 6 to 11.** 0.31 to 0.63 mg three times daily.

*Maximum:* 0.63 mg three times daily.

***DOSAGE ADJUSTMENT*** For elderly patients using Xopenex, dosage limited to 0.63 mg three times daily every 6 to 8 hr.

Route	Onset	Peak	Duration
Inhalation	10-17 min	1.5 hr	5-6 hr

## Mechanism of Action

Attaches to  $\beta_2$  receptors on bronchial cell membranes, which stimulates the intracellular enzyme adenylyl cyclase to convert adenosine triphosphate to cAMP. Increased intracellular cAMP level relaxes bronchial smooth muscle and inhibits histamine release from mast cells.

## Contraindications

Hypersensitivity to levalbuterol, racemic albuterol, or their components

## Interactions

### DRUGS

*beta blockers*: Possibly block pulmonary effects of levalbuterol; may cause severe bronchospasms

*digoxin*: Decreased blood digoxin level and effectiveness

*loop or thiazide diuretics*: Increased risk of hypokalemia

*MAO inhibitors, sympathomimetics, tricyclic*

*antidepressants*: Increased risk of adverse cardiovascular effects

## Adverse Reactions

**CNS**: Anxiety, chills, dizziness, dysphonia, hypertonia, insomnia, migraine headache, nervousness, paresthesia, syncope, tremor

**CV:** **Arrhythmias**, chest pain, hypertension, **hypotension**, tachycardia

**EENT:** Dry mouth and throat, rhinitis, sinusitis

**GI:** Diarrhea, gastroesophageal reflux disease (GERD), indigestion, nausea, vomiting

**MS:** Leg cramps, myalgia

**RESP:** **Asthma exacerbation**, cough, dyspnea, **paradoxical bronchospasm**

**SKIN:** Rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, lymphadenopathy, **metabolic acidosis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug should not be used during labor and delivery unless there are no other alternatives because drug may interfere with uterine contractility.
- Be aware drug has not been approved for management of preterm labor. Serious adverse reactions, including maternal pulmonary edema have occurred during or following treatment of premature labor.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use levalbuterol cautiously in patients with arrhythmias, diabetes mellitus, hypertension, hyperthyroidism, or a history of seizures.
- Give oral solution form only by nebulizer.
- Monitor blood pressure and pulse rate before and after nebulizer treatment.
- Observe for dyspnea, increased coughing and wheezing, because drug may provoke paradoxical bronchospasm.

## **PATIENT TEACHING**

- Teach patient how to use levalbuterol nebulizer and to measure correct dose.
- Instruct patient to prime inhaler before using it for the first time or when it hasn't been used for more than 3 days by releasing 4 test sprays into the air, aiming it away from her face. Tell patient that inhaler canister must be shaken well before each use, including when priming.
- Show patient how to clean nebulizer or inhaler, and explain the need to do so at least once weekly.
- Instruct patient to notify prescriber if drug fails to work or if she needs more treatments because asthma is worsening.
- Inform patient that common side effects with levalbuterol use include chest pain, nervousness, palpitations, rapid heart rate, and tremor.
- Instruct patient not to increase dosage or frequency unless told by prescriber.
- Urge patient to stop drug and call prescriber if she has paradoxical bronchospasm.
- Instruct patient to use inhalation solution within 2 weeks of opening the foil pouch and to protect drug from heat and light.
- Inform patient that inhaler canister has a dose indicator display, which will change after every tenth actuation. When nearing the end of usable inhalations, the color behind the number in the dose indicator window will change to red. Tell patient to discard the inhaler when the display window shows zero.
- Urge patient to consult prescriber before using OTC or other drugs.
- Tell women of childbearing age to notify prescriber if pregnancy is suspected or known. Also tell mothers wishing to breastfeed to discuss

this with prescriber before doing so.

# levamlodipine

## Conjupri

### Class and Category

*Pharmacologic class:* Dihydropyridine calcium channel blocker

*Therapeutic class:* Antihypertensive

### Indications and Dosages

➤ *To treat hypertension*

#### **TABLETS**

**Adults.** *Initial:* 2.5 mg once daily increased after 7 to 14 days to 5 mg once daily, as needed. *Maximum:* 5 mg once daily. Children ages 6 to 17. *Initial:* 1.25 to 2.5 mg once daily. *Maximum:* 2.5 mg once daily.

***DOSAGE ADJUSTMENT*** For elderly or frail patients and patients with hepatic insufficiency, initial dose decreased to 1.25 mg once daily and titrated slowly.

Route	Onset	Peak	Duration
P.O.	Unknown	6 to 12 hr	Unknown

### Mechanism of Action

Inhibits the transmembrane influx of calcium ions into vascular smooth muscle to produce peripheral vasodilation, which reduces peripheral vascular resistance and thus reduces blood pressure.

## Contraindications

Hypersensitivity to levamlodipine, amlodipine, or their components

## Interactions

### DRUGS

*immunosuppressants (cyclosporine, tacrolimus), simvastatin*: Increased systemic exposure of these drugs with increased risk of adverse reactions

*moderate and strong CYP3A inducers*: Decreased concentration of levamlodipine

*moderate and strong CYP3A inhibitors*: Increased exposure of levamlodipine and risk of adverse reactions

*sildenafil*: Increased risk of hypotension

## Adverse Reactions

**CNS:** Abnormal dreams, anxiety, asthenia, depersonalization, depression, dizziness, extrapyramidal disorder, fatigue, hypoesthesia, insomnia, malaise, nervousness, paresthesia, peripheral neuropathy, rigors, somnolence, syncope, thirst, tremor, vertigo

**CV:** **Arrhythmias (including atrial fibrillation, ventricular tachycardia), bradycardia**, chest pain, edema, palpitation, peripheral ischemia, tachycardia, vasculitis

**EENT:** Abnormal vision, conjunctivitis, diplopia, dry mouth, epistaxis, eye pain, gingival hyperplasia, tinnitus

**ENDO:** Hot flashes, hyperglycemia

**GI:** Abdominal pain, anorexia, cholestasis, constipation, diarrhea, dysphagia, elevated liver enzymes, flatulence, **hepatitis**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Female and male sexual dysfunction, nocturia, urinary frequency or other micturition disorders

**HEME:** **Leukopenia**, **purpura**, **thrombocytopenia**

**MS:** Arthralgia, arthrosis, back pain, muscle cramps, myalgia

**RESP:** Dyspnea

**SKIN:** Diaphoresis, **erythema multiforme**, flushing, pruritus, rash

**Other:** **Angioedema**, generalized pain, **hypersensitivity reactions**, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Monitor patient's blood pressure to determine effectiveness. Know that symptomatic hypotension is possible, particularly in patients with severe

aortic stenosis.

**WARNING** Monitor patient closely after levamlodipine is initiated or dosage is increased, especially in patients with severe obstructive coronary artery disease, because drug may cause an acute myocardial infarction or worsen angina.

## PATIENT TEACHING

- Instruct patient to inform prescriber of all medications taken, including over-the-counter and herbal products.
- Tell patient to keep levamlodipine out of the light.

**WARNING** Urge patient to seek immediate emergency care if serious allergic reactions occur or heart disorders worsen.

## levetiracetam

**Keppra, Keppra XR, Spritam**

## Class and Category

*Pharmacologic class:* Pyrrolidine derivative

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

➤ *As adjunct to treat partial seizures*

## I.V. INFUSION, ORAL SOLUTION

**Adults and adolescents age 16 and over.** *Initial:* 500 mg (I.V.: infused over 15 min) twice daily, increased by 1,000 mg daily every 2 wk, if needed, until the recommended daily dose of 3,000 mg given in two divided doses is reached. *Maximum:* 3,000 mg daily.

**Children ages 4 to 16.** *Initial:* 10 mg/kg (I.V.: infused over 15 min) twice daily, increased by 20 mg/kg daily every 2 wk until recommended daily dose of 60 mg/kg given in 2 divided doses is reached. *Maximum:* 3,000 mg daily.

**Children 6 months to 4 years.** *Initial:* 10 mg/kg (I.V.: infused over 15 min) twice daily, increased by 20 mg/kg daily every 2 wk until the recommended daily dose of 50 mg/kg given in 2 divided doses is reached.

**Infants 1 to 6 months of age.** *Initial:* 7 mg/kg (I.V.: infused over 15 min) twice daily, increased by 14 mg/kg every 2 wk until recommended daily dose of 42 mg/kg given in 2 divided doses is reached.

## **TABLETS (KEPPRA)**

**Adults and adolescents ages 16 and over.** *Initial:* 500 mg twice daily, increased by 1,000 mg daily every 2 wk, if needed, until the recommended daily dose of 3,000 mg given in two divided doses is reached. *Maximum:* 3,000 mg daily.

**Children ages 4 to 16 weighing more than 40 kg (88 lb).** *Initial:* 500 mg twice daily, increased by 1,000 mg daily every 2 wk to a maximum recommended daily dose. *Maximum:* 1,500 mg twice daily.

**Children ages 4 to 16 weighing 20 to 40 kg (44 to 88 lb):** *Initial:* 250 mg twice daily, increased by 500 mg daily every 2 wk to a maximum recommended daily dose. *Maximum:* 750 mg twice daily. *Maximum:* 750 mg twice daily.

## **TABLETS (SPRITAM)**

**Adults and children age 4 and over weighing over 40 kg (88 lb).** *Initial:* 500 mg twice daily, increased by 1,000 mg daily every 2 wk to a maximum recommended daily dose. *Maximum:* 3,000 mg daily given in 2 divided doses.

**Children age 4 and over weighing 20 to 40 kg (44 to 88 lb).** *Initial:* 250 mg twice daily, increased by 500 mg every 2 wk until maximum recommended daily dose is reached. *Maximum:* 1,500 mg daily in 2 divided doses.

## **XR TABLETS**

**Adults and children age 12 and over weighing 50 kg (110 lb) or more.** 1,000 mg once daily, increased by 1,000 mg daily every 2 wk until maximum recommended daily dose is reached. *Maximum:* 3,000 mg once daily.

- *As adjunct to treat myoclonic seizures in patients with juvenile myoclonic epilepsy*

## **I.V. INFUSION, ORAL SOLUTION, TABLETS**

**Adults and children age 12 and over.** *Initial:* 500 mg (I.V.: infused over 15 min) twice daily, increased by 1,000 mg daily every 2 wk to maximum recommended dose. *Maximum:* 3,000 mg daily given in 2 divided doses.

- *As adjunct to treat primary generalized tonic-clonic seizures in patients with idiopathic generalized epilepsy*

## **I.V. INFUSION, ORAL SOLUTION, TABLETS (KEPPRA)**

**Adults and children age 16 and over.** *Initial:* 500 mg (I.V.: infused over 15 min) twice daily, increased by 1,000 mg daily every 2 wk to the maximum recommended dose

given in 2 divided doses. *Maximum:* 3,000 mg given in 2 divided doses.

**Children ages 6 to 16.** *Initial:* 10 mg/kg (I.V.: infused over 15 min) twice daily, increased by 20 mg/kg daily every 2 wk to the maximum recommended daily dose and given in 2 divided doses. *Maximum:* 60 mg/kg daily in 2 divided doses.

## **TABLETS (SPRITAM)**

**Adults and children age 6 and over weighing over 40 kg (88 lb).** *Initial:* 500 mg twice daily, increased by 1,000 mg daily every 2 wk to recommended daily dose of 3,000 mg given in 2 divided doses.

**Children age 6 and over weighing 20 to 40 kg (44 to 88 lb):** *Initial:* 250 mg twice daily, increased by 500 mg every 2 wk to the recommended daily dose of 1,500 mg given in 2 divided doses.

**DOSAGE ADJUSTMENT** Maximum dosage reduced to 2,000 mg daily for patients with creatinine clearance of 50 to 80 ml/min; to 1,500 mg daily for clearance of 30 to 50 ml/min; and to 1,000 mg daily for clearance less than 30 ml/min. For patients with end-stage renal disease who are having dialysis, expect to give another 250 to 500 mg, as prescribed, after each dialysis session. For children who can't tolerate maximum daily dose, dosage reduced to point of tolerance.

## **Mechanism of Action**

May protect against secondary generalized seizure activity by preventing coordination of epileptiform burst firing. Levetiracetam doesn't seem to involve inhibitory and excitatory neurotransmission.

# Contraindications

Hypersensitivity to levetiracetam or its components

# Interactions

## DRUGS

None reported

# Adverse Reactions

**CNS:** Abnormal gait, affect lability, aggression, agitation, altered mood, amnesia, anger, anxiety, apathy, asthenia, ataxia, behavioral difficulties (children), choreoathetosis, confusion, coordination difficulties, depersonalization, depression, dizziness, dyskinesia, emotional lability, fatigue, hallucinations, headache, hostility, hypersomnia, increased reflexes, insomnia, involuntary movements, irritability, lethargy, mental or mood changes, nervousness, neurosis, panic attacks, paranoia, paresthesia, personality disorder, psychosis, **seizures**, somnolence, **suicidal ideation**, vertigo

**CV:** Elevated diastolic blood pressure (children up to 4 years of age), **hypotension**

**EENT:** Amblyopia, conjunctivitis, diplopia, ear pain, nasal congestion, nasopharyngitis, pharyngitis, rhinitis, sinusitis

**GI:** Abdominal pain (upper), anorexia, constipation, diarrhea, elevated liver enzymes, gastroenteritis, **hepatic failure, hepatitis, pancreatitis**, vomiting

**GU:** **Acute kidney injury**, albuminuria

**HEME:** **Agranulocytosis**; decreased hematocrit, hemoglobin, and red blood cell counts; elevated eosinophil count; **leukopenia; neutropenia; pancytopenia; thrombocytopenia**

**MS:** Arthralgia, joint sprain, muscle weakness, neck pain

**RESP:** **Asthma**, cough, dyspnea

**SKIN:** Alopecia, ecchymosis, **erythema multiforme**, pruritus, rash, skin discoloration, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, vesiculobullous rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, dehydration, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms, **hyponatremia**, infection, influenza, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug causes fetal harm.
- Drug levels may decrease during pregnancy requiring dosage adjustments.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that children weighing 20 kg or less should be given only the oral solution form.
- Know that the intravenous form of levetiracetam should be used only as an alternative for patients when oral administration is temporarily not possible.

- Keep in mind that when switching patient from oral dosing to intravenous dosing and from intravenous dosing to oral dosing, no dosage or frequency changes are needed.
- For I.V. use, dilute parenteral levetiracetam in 100 ml of compatible diluent, such as normal saline injection, lactated Ringer's injection, or dextrose 5% injection. Use within 24 hours. Infuse each dose over 15 minutes.

**WARNING** Monitor patient for hypersensitivity reactions.

Know that anaphylaxis or angioedema have occurred with levetiracetam therapy as early as after the first dose, but also at other times during treatment. Monitor patient for difficulty breathing, hives, hypotension, rash, and swelling. If present, withhold drug, notify prescriber immediately, and provide emergency supportive care, as ordered. Expect drug to be discontinued.

- Monitor patient for seizure activity during therapy. As appropriate, implement seizure precautions according to facility policy.
- Avoid stopping drug abruptly because doing so may increase seizure activity. Expect to taper dosage gradually.
- Monitor patient for bleeding, fever, recurrent infections, or significant weakness. If present, notify prescriber and expect to obtain a complete blood count to assess patient's hematological status.
- Assess compliance, especially during the first 4 weeks of therapy, when certain adverse effects, including abnormal behaviors, coordination problems, fatigue, and somnolence may be more likely to occur.
- Monitor blood pressure in children because increased diastolic blood pressure may occur in patients up to 4 years old.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Monitor patient for a rash and other adverse skin reactions because serious dermatological reactions have occurred with levetiracetam therapy. Although these adverse reactions usually appear within 14 to 17 days after therapy has begun, some have occurred as late as 4 months later. Notify prescriber at the first sign of a rash and expect drug to be discontinued.

- Monitor pregnant patient closely, especially during third trimester, because physiological changes associated with pregnancy may gradually decrease plasma levetiracetam levels. Monitoring should continue through the postpartum period.

## **PATIENT TEACHING**

- Instruct patient prescribed Spritam form of levetiracetam to place tablet on tongue with a dry hand and immediately follow with a sip of water as it is intended to disintegrate in the mouth when taken with a sip of water.
  - Remind patient prescribed XR in tablet form to swallow tablet whole. It should not be broken, chewed, or crushed. Reassure patient that they may occasionally notice something that looks like swollen pieces of the original tablet in stool but not to be concerned.
  - Tell patient to seek immediate emergency care if an allergic reaction occurs, especially if he experiences difficulty breathing, hives, low blood pressure, rash, or swelling.
  - Caution patient that levetiracetam may cause dizziness and drowsiness, especially during first 4 weeks of therapy.
  - Advise patient to avoid hazardous activities until drug's CNS effects are known.
  - Caution patient not to stop taking levetiracetam abruptly; inform her that drug dosage should be tapered under prescriber's direction to reduce the risk of breakthrough seizures.
  - Explain to patient and family that levetiracetam may cause mental and behavioral changes, such as aggression, depression, irritability, and rarely psychotic symptoms. The prescriber should be contacted about any bothersome changes.
  - Advise patient to keep taking other anticonvulsants, as ordered, while taking levetiracetam.
  - Instruct patient to see prescriber regularly so that her progress can be monitored.
  - Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns immediately.
  - Emphasize importance of notifying prescriber at the first sign of a rash.
-

# levocetirizine

**Xyzal**

## Class and Category

*Pharmacologic class:* H<sub>1</sub>-receptor antagonist

*Therapeutic class:* Antihistamine

## Indications and Dosages

- *To treat uncomplicated skin manifestations of chronic idiopathic urticaria*

### **TABLETS, ORAL SOLUTION**

**Adults under the age of 65 and children age 12 and over.** 2.5 or 5 mg once daily in evening. *Maximum:* 5 mg daily.

**Children ages 6 to 11.** 2.5 mg once daily in evening. *Maximum:* 2.5 mg daily.

**Children 6 months to age 5.** 1.25 mg once daily in evening. *Maximum:* 1.25 mg daily.

***DOSAGE ADJUSTMENT*** For adult patient with mild renal impairment (creatinine clearance 50 to 80 ml/min), dosage shouldn't exceed 2.5 mg daily. For adult patient with moderate renal impairment (creatinine clearance 30 to 50 ml/min), dosage shouldn't exceed 2.5 mg once every other day. For adult patient with severe renal impairment (creatinine clearance 10 to 30 ml/min), dosage shouldn't exceed 2.5 mg once every 3 to 4 days. Dosages for children should not exceed maximum dose because systemic exposure is about twice that of adults.

- *To relieve symptoms associated with pediatric perennial allergic rhinitis*

## **ORAL SOLUTION, TABLETS**

**Children 6 months of age to 2 years.** 1.25 mg once daily in evening. *Maximum:* 1.25 mg daily.

***DOSAGE ADJUSTMENT*** Maximum dosage should not be exceeded because systemic exposure in children is about twice that of adults.

## **Mechanism of Action**

Binds to central and peripheral H<sub>1</sub> receptors, competing with histamine for these sites and preventing it from reaching its site of action. By blocking histamine, levocetirizine produces antihistamine effects, inhibiting respiratory, vascular, and GI smooth-muscle contraction; decreasing capillary permeability, which reduces wheals, flares, and itching; and decreasing salivary and lacrimal gland secretions to relieve chronic urticaria and signs and symptoms of allergic rhinitis.

## **Contraindications**

Children ages 6 months to 11 years with impaired renal function; creatinine clearance less than 10 ml/min (end-stage renal disease); hemodialysis; hypersensitivity to levocetirizine, cetirizine or their components

## **Interactions**

### **DRUGS**

*CNS depressants:* Possibly increased CNS depression

*ritonavir*: Possibly increased risk of adverse effects of levocetirizine

*theophylline*: Possibly decreased clearance of levocetirizine

## ACTIVITIES

*alcohol use*: Possibly increased CNS depression

## Adverse Reactions

**CNS:** Aggression, agitation, asthenia, depression, dizziness, fatigue, fever, hallucinations, insomnia, movement disorders, myoclonus and extrapyramidal symptoms, paraesthesia, **seizures**, somnolence, **suicidal ideation**, syncope, tic, tremor, vertigo

**CV:** Edema, palpitations, tachycardia

**EENT:** Blurred vision, dry mouth, epistaxis, nasopharyngitis, pharyngitis, visual disturbances

**GI:** **Hepatitis**, increased appetite, nausea, vomiting

**GU:** Dysuria, urinary retention

**MS:** Arthralgia, myalgia

**RESP:** Cough, dyspnea

**SKIN:** Acute generalized exanthematous pustulosis, fixed drug eruption, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if levocetirizine is present in breast milk although cetirizine is present.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use levocetirizine cautiously in patients with predisposing risk factors for urinary retention, such as prostatic hyperplasia or spinal cord lesion. Monitor patient's intake and output closely. If urinary retention is suspected, notify prescriber and expect drug to be discontinued if confirmed.
- Monitor patient for abnormal thinking, such as desire to harm oneself. Notify prescriber immediately if present.
- Expect to stop drug at least 72 hours before skin tests for allergies because drug may inhibit cutaneous histamine response, thus producing false-negative results.

## PATIENT TEACHING

- Instruct patient to take drug exactly as prescribed. For oral solution, patient should use appropriate measuring device.
- Urge patient to avoid alcohol while taking levocetirizine
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to notify prescriber if he is feeling bladder fullness or notices that his urine output is significantly less than his intake.
- Warn patient that if he develops abnormal thoughts, especially thoughts of harming himself, he should notify prescriber immediately.
- Alert patient taking levocetirizine long-term that rebound itching may occur within days after drug is discontinued.

**levofloxacin**

# Levaquin

## Class and Category

*Pharmacologic class:* Fluoroquinolone

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To reduce incidence or progression of inhalation anthrax after exposure to aerosolized Bacillus anthracis; to treat plague, including pneumonic and septicemic plague, caused by Yersinia pestis; to provide prophylaxis for plague*

### **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults and children weighing 50 kg (110 lb) or more.**

500 mg (over 60 to 90 min for I.V. infusion) daily for 60 days for treatment of inhalation anthrax and 10 to 14 days for treatment of plague.

**Children weighing less than 50 kg (110 lb) (but no less than 30 kg for tablet form) and 6 months of age or older.** 8 mg/kg (over 60 to 90 min for I.V. infusion) or 250 mg (tablet form) every 12 hr for 60 days for treatment of inhalation anthrax and 10 to 14 days for treatment of plague. *Maximum:* 250 mg/dose.

- *To treat acute bacterial sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae*

### **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 500 mg daily (over 60 to 90 min for I.V. infusion) for 10 to 14 days. Or 750 mg daily for 5 days.

- *To treat acute exacerbation of chronic bacterial bronchitis caused by H. influenzae, H. parainfluenzae, M. catarrhalis, S. pneumoniae, or Staphylococcus aureus*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 500 mg daily (over 60 to 90 min for I.V. infusion) for 7 days.

- *To treat community-acquired pneumonia caused by Chlamydophila pneumoniae, H. influenzae, H. parainfluenzae, Klebsiella pneumoniae, Legionella pneumophila, M. catarrhalis, Mycoplasma pneumoniae, S. aureus, or S. pneumoniae*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 500 mg daily (over 60 to 90 min for I.V. infusion) for 7 to 14 days. Alternatively, for infection caused by *C. pneumoniae*, *H. influenzae*, *H. parainfluenzae*, *M. pneumoniae*, or *S. pneumoniae*, 750 mg daily (over 90 min for I.V. infusion) for 5 days.

- *To treat uncomplicated UTI caused by Escherichia coli, K. pneumoniae, or Staphylococcus saprophyticus*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 250 mg daily (over 60 min for I.V. infusion) for 3 days.

- *To treat complicated UTI caused by Enterococcus faecalis, E. cloacae, E. coli, K. pneumoniae, Proteus mirabilis, or Pseudomonas aeruginosa; acute pyelonephritis caused by E. coli*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 250 mg daily (over 60 min for I.V. infusion) for 10 days.

- *To treat complicated UTI caused by E. coli, K. pneumoniae, or P. mirabilis or acute pyelonephritis caused by E. coli*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 750 mg daily (over 90 min for I.V. infusion) for 5 days.

- *To treat mild to moderate skin and soft-tissue infections caused by S. aureus or Streptococcus pyogenes*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 500 mg daily (over 60 to 90 min for I.V. infusion) for 7 to 10 days.

- *To treat complicated skin and soft-tissue infections caused by methicillin-sensitive E. faecalis, Proteus mirabilis, S. aureus, or S. pyogenes; to treat nosocomial pneumonia caused by E. coli, H. influenzae, K. pneumoniae, Pseudomonas aeruginosa, S. aureus, Serratia marcescens, or S. pneumoniae*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 750 mg daily (over 90 min for I.V. infusion) for 7 to 14 days.

- *To treat chronic bacterial prostatitis caused by E. coli, E. faecalis, or S. epidermidis*

## **TABLETS, I.V. INFUSION, ORAL SOLUTION**

**Adults.** 500 mg daily (over 60 to 90 min for I.V. infusion) for 28 days.

**DOSAGE ADJUSTMENT** For patients with creatinine clearance of 20 to 49 ml/min and normal dosage is 750 mg, dosage interval increased to every 48 hr; for normal dosage of 500 mg, one dose of 500 mg given, followed by 250 mg every 24 hr. For patients with creatinine clearance of 10 to 19 ml/min or who are receiving dialysis, and normal dosage is 750 mg, one dose of 750 mg given, followed by 500 mg every 48 hr; for normal dosage of 500 mg, one dose of 500 mg given, followed by 250 mg every 48 hr; and for normal dosage of 250 mg (no information on dosing adjustment available for patient on dialysis at this dosage), dosage interval increased to every 48 hr unless the 250 mg dosage is used to treat uncomplicated UTI, then no dosage adjustment is required. Supplemental doses of levofloxacin are not required following continuous ambulatory peritoneal dialysis or hemodialysis because dialysis is not effective in removing levofloxacin from the body.

## Mechanism of Action

Interferes with bacterial cell replication by inhibiting the bacterial enzyme DNA gyrase, which is essential for repair and replication of bacterial DNA.

## Contraindications

Hypersensitivity to levofloxacin, other fluoroquinolones, or their components; myasthenia gravis

## Interactions

### DRUGS

*aluminum-, calcium-, or magnesium-containing antacids; didanosine; iron; sucralfate; zinc:* Reduced GI absorption of levofloxacin

*cyclosporine:* Increased risk of nephro-toxicity

*NSAIDs:* Possibly increased CNS stimulation and risk of seizures

*oral anticoagulants:* Increased anticoagulant effect and risk of bleeding

*oral antidiabetic drugs:* Possibly hyperglycemia or hypoglycemia

*theophylline:* Increased blood theophylline level and risk of toxicity

## Adverse Reactions

**CNS:** Agitation, anxiety, CNS stimulation, confusion, delirium, depression, disorientation, disturbance in attention, dizziness, electroencephalogram abnormalities, **encephalopathy** (rare), fever, hallucinations, headache, hoarse voice, **increased intracranial pressure**, insomnia, light-headedness, memory impairment, nervousness, nightmares, paranoia, peripheral neuropathy, **pseudotumor cerebri**, psychosis, restlessness, **seizures**, sleep disturbance, **suicidal ideation**, toxic psychoses, tremors

**CV:** **Aortic dissection**, **arrhythmias**, leukocytoclastic vasculitis, **prolonged QT interval**, **rupture of aortic aneurysm**, tachycardia, **torsades de pointes**, vasculitis, vasodilation

**EENT:** Blurred vision, decreased visual acuity, diplopia, dysphonia, scotoma, smell or taste perversion, tinnitus, uveitis

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, **acute hepatic failure or necrosis**, anorexia, constipation, diarrhea, flatulence, **hepatitis**,

**hepatotoxicity**, indigestion, jaundice, nausea,

**pseudomembranous colitis**, vomiting

**GU: Acute renal failure or insufficiency**, crystalluria, interstitial nephritis, vaginal candidiasis

**HEME: Agranulocytosis, aplastic anemia**, eosinophilia, **hemolytic anemia, leukopenia, pancytopenia, prolonged International Normalized Ratio (INR) and prothrombin time, thrombocytopenia**

**MS: Arthralgia, arthritis, back pain, elevated muscle enzymes, gait abnormality, myalgia, rhabdomyolysis**, tendon or muscle rupture, tendinopathy

**RESP: Hypersensitivity pneumonitis**

**SKIN: Erythema multiforme**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other: Anaphylaxis, angioedema**, exacerbation of myasthenia gravis, **multiorgan failure**, serum sickness

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy and for two days after last dose; alternatively, mother may consider pumping and discarding breast milk during drug therapy and for two day after last dose.

# Nursing Considerations

- Use levofloxacin cautiously in patients with renal insufficiency. Monitor renal function as appropriate during treatment.
- Use drug cautiously in patients with CNS disorders, such as epilepsy or renal dysfunction, as well as certain drug therapies, that may lower the seizure threshold. Also use cautiously in patients taking corticosteroids, especially elderly patients, because of increased risk of tendon rupture.
- Expect to obtain culture and sensitivity tests before levofloxacin treatment begins.
- Know that levofloxacin therapy should begin as soon as possible after suspected or confirmed exposure to *Y. pestis*.
- Avoid giving drug within 2 hours of antacids.
- Give parenteral form over 60 to 90 minutes, depending on dosage, because bolus or rapid I.V. delivery may cause hypotension.

**WARNING** Stop levofloxacin at first sign of hypersensitivity, including rash, because drug may lead to anaphylaxis. Reaction may occur after first dose. Expect to give epinephrine and provide supportive care.

- Monitor blood glucose level, especially in diabetic patient who takes an oral antidiabetic or uses insulin, because levofloxacin may alter blood glucose level. If so, notify prescriber, stop drug immediately if patient has hypoglycemia, and provide prescribed treatment.
- Monitor QT interval if needed. If it lengthens, notify prescriber at once and stop drug. Patients with cardiomyopathy, hypokalemia, or significant bradycardia and those receiving a class IA or III antiarrhythmic shouldn't receive levofloxacin.

**WARNING** Be aware that levofloxacin increases risk of aortic aneurysm and dissection within two months following drug use, especially in elderly patients.

- Notify prescriber if patient has symptoms of peripheral neuropathy (altered sensations of light touch, pain, temperature, position sense, or vibration sense), which could be permanent; or CNS or psychiatric

abnormalities (i.e., CNS stimulation, increased ICP, psychosis, or seizures), which may lead to more serious adverse reactions, such as suicidal ideation. In each case, expect to discontinue levofloxacin.

- Watch for evidence of tendon rupture (inflammation, pain, swelling) during and up to several months after therapy, especially in children, elderly patients, patients receiving corticosteroids, and patients with heart, kidney, and lung transplants. Notify prescriber about suspected tendon rupture, and have patient rest and refrain from exercise until tendon rupture has been ruled out. If present, expect to provide supportive care, as ordered.
- Be aware that children have a higher incidence of musculoskeletal adverse reactions, especially arthralgia, arthritis, gait abnormality, and tendinopathy. Report any complaint involving the musculoskeletal system promptly to prescriber.
- Monitor patient's bowel elimination. If diarrhea develops, obtain stool culture to check for pseudomembranous colitis. If confirmed, expect to stop drug and give antibiotics effective against *Clostridium difficile*, electrolytes, and fluids.
- Know that fluoroquinolones like levofloxacin have caused disabling and potentially irreversible serious adverse reactions from different body systems that can occur together in the same patient. These reactions can occur within hours to weeks after starting the drug and usually cause central nervous system effects, peripheral neuropathy, tendinitis, and tendon rupture. All ages of patients and patients without any preexisting risk factors have experienced these reactions. Notify prescriber and expect to discontinue levofloxacin immediately at the first signs or symptoms of any serious adverse reactions.

## PATIENT TEACHING

- Tell patient prescribed oral solution to take it 1 hour before or 2 hours after eating.
- Advise patient to increase fluid intake during therapy to prevent crystalluria.
- Direct patient to take an antacid, didanosine, iron, sucralfate, or zinc at least 2 hours before or after levofloxacin.
- Tell patient to complete the drug as prescribed, even if symptoms subside.
- Urge patient to avoid excessive sun exposure and to wear sunscreen because of increased risk of photosensitivity. Tell patient to notify prescriber at first sign of photosensitivity.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Tell patient to stop drug and notify prescriber if he develops abnormal changes in motor or sensory function, or if he experiences bruising right after an injury in a tendon area, hearing or feeling a pop or snap in a tendon area, or is unable to move the affected area or bear weight. Inform patient tendon problems may be permanent.
- Urge patient experiencing a rash or other allergic reactions to stop drug and tell prescriber.
- Urge patient to notify prescriber if patient experiences pain or tenderness in the upper right side of the abdomen.
- Advise diabetic patient to monitor blood glucose level and report changes.
- Urge patient to tell prescriber about severe diarrhea, even if it's more than 2 months after drug therapy ends. Additional treatment may be needed.
- Advise patient to notify prescriber about heart palpitations or loss of consciousness.
- Advise patient to stop taking levofloxacin immediately and notify prescriber if any persistent, serious, or worsening adverse effects occur.

## levomilnacipran hydrochloride

**Fetzima**

### **Class and Category**

*Pharmacologic class:* Selective norepinephrine and serotonin reuptake inhibitor (SSNRI)

*Therapeutic class:* Antidepressant

### **Indications and Dosages**

- *To treat major depressive disorder*

## **E.R. CAPSULES**

**Adults.** *Initial:* 20 mg once daily for 2 days then increased to 40 mg once daily. Dosage further increased in 40-mg increments at intervals of 2 or more days, as needed.

*Maximum:* 120 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with moderate renal impairment (creatinine clearance of 30 to 59 ml/min), maintenance dosage should not exceed 80 mg once daily. For patients with severe renal impairment (creatinine clearance of 15 to 29 ml/min), maintenance dosage should not exceed 40 mg once daily.

## **Mechanism of Action**

Inhibits reuptake of norepinephrine and serotonin by CNS neurons without affecting uptake of dopamine or other neurotransmitters, thereby increasing amount of norepinephrine and serotonin available in nerve synapses in the central nervous system. Elevated norepinephrine and serotonin levels may relieve symptoms of depression and may improve symptoms of fibromyalgia, including central analgesic effect.

## **Contraindications**

Hypersensitivity to levomilnacipran, milnacipran, or its components; use within 14 days of MAO inhibitor therapy, including reversible agents such as intravenous methylene blue or linezolid

## **Interactions**

## DRUGS

*antipsychotics or other dopamine antagonists, MAO inhibitors, other serotonergic drugs (amphetamines, buspirone, fentanyl, lithium, St. John's wort, tramadol, tricyclic antidepressants, triptans, tryptophan), selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors:* Possibly development of neuroleptic malignant syndrome-like reactions or serotonin syndrome  
*aspirin, NSAIDs, warfarin:* Increased risk of bleeding  
*CNS-active drugs:* Possibly increased CNS effects  
*strong CYP3A4 inhibitors such as clarithromycin, itraconazole, ketoconazole:* Increased exposure of levomilnacipran resulting in increased risk of adverse reactions

## ACTIVITIES

*alcohol use:* Increased risk of adverse reactions

## Adverse Reactions

**CNS:** Activation of hypomania or mania, aggression, agitation, anger, anxiety, delirium, depression, dizziness, extrapyramidal disorder, fatigue, fever, hallucinations, headache, hypoesthesia, insomnia, irritability, loss of consciousness, migraine, panic attack, paresthesia, **seizures, serotonin syndrome, suicidal ideation,** syncope, thirst, tremor

**CV:** Chest pain, elevated cholesterol levels, **extrasystoles,** hypertension, **hypertensive crisis, hypotension,** increased heart rate, palpitations, peripheral edema, **supraventricular tachycardia,** tachycardia, **Takotsubo cardiomyopathy**

**EENT:** Angle-closure glaucoma, blurred vision, conjunctival hemorrhage, dry eye, epistaxis, mydriasis

**ENDO:** Hot flashes

**GI:** Abdominal distention or pain, anorexia, constipation, diarrhea, elevated liver enzymes, flatulence, nausea, vomiting

**GU:** Decreased libido, dysuria, ejaculation disorder, erectile dysfunction, hematuria, prostatitis, proteinuria, scrotal or testicular pain, testicular swelling, urinary hesitation or retention

**HEME:** Bleeding risk including **hemorrhage**, hematoma

**RESP:** Dyspnea,

**SKIN:** Dry skin, ecchymosis, **erythema multiforme**, excessive sweating including night sweats, flushing, petechiae pruritus, rash, urticaria

**Other:** Hyponatremia

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-844-405-6185 or <https://www.womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/antidepressants/>.
- Drug may cause fetal harm. Neonates exposed to drug late in the third trimester have developed complications requiring prolonged hospitalization, respiratory support, and tube feeding. Such complications can arise immediately upon delivery.
- Use with caution, especially late in the third trimester, only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug use late in pregnancy increases risk of postpartum hemorrhage.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding. If breastfeeding occurs, infant should be monitored for agitation, irritability, or poor feeding or weight gain.

## Nursing Considerations

- Use levomilnacipran cautiously in patients with cardiac disease or significant hypertension and in patients with renal impairment. Also use cautiously in patients with a history of dysuria, especially men with prostatic hypertrophy, prostatitis, and other lower urinary tract obstructive disorders.
- Know that at least 14 days should elapse between stopping an MAO inhibitor and starting levomilnacipran. At least 7 days should elapse between stopping levomilnacipran and starting an MAO inhibitor antidepressant.
- Measure patient's blood pressure and heart rate before starting and periodically during levomilnacipran therapy because drug can raise blood pressure and heart rate. If hypertension or tachycardia occurs and persists, notify prescriber and expect to reduce dosage or discontinue drug.
- Watch closely for suicidal tendencies, especially when therapy starts and after dosage changes.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of selective serotonin reuptake inhibitors such as levomilnacipran. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, it can resemble neuroleptic malignant syndrome with autonomic instability with possible rapid fluctuation of vital signs, mental status changes, and muscle rigidity. If symptoms occur, notify

prescriber immediately, expect to discontinue drug, and provide supportive care.

- Assess effectiveness of levomilnacipran periodically being aware that therapy may be required for several months or longer. Expect to taper drug when no longer needed, as ordered, to minimize adverse reactions.

## **PATIENT TEACHING**

- Instruct patient to take levomilnacipran capsules whole and not to chew, crush, or open capsules.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute-closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution patient against stopping drug abruptly because serious adverse effects may result.
- Instruct patient to alert all prescribers of levomilnacipran therapy.
- Tell patient to have his blood pressure monitored regularly throughout levomilnacipran therapy.
- Advise patient to avoid activities, such as driving, that require alertness until the CNS effects of levomilnacipran are known.
- Monitor patient to avoid aspirin and NSAIDs, if possible, while taking levomilnacipran and to take bleeding precautions.
- Instruct patient to report any persistent, severe, or unusual adverse effects to prescriber immediately.

## **levothyroxine sodium**

**(L-thyroxine sodium, T<sub>4</sub>, thyroxine sodium)**

# Eltroxin (CAN), Euthyrox, Levo-T, Levoxyl, Synthroid, Tirosint, Unithroid

## Class and Category

*Pharmacologic class:* Synthetic thyroxine (T<sub>4</sub>)

*Therapeutic class:* Thyroid hormone replacement

## Indications and Dosages

- *To treat primary, secondary, or tertiary hypothyroidism*

### CAPSULES, TABLETS

**Adults and adolescents in whom growth and puberty are complete.** *Initial:* 1.6 mcg/kg once daily. Dosage adjusted in 12.5 to 25 mcg every 4 to 6 wk, as needed.

*Usual maintenance dose:* 100 to 125 mcg daily.

**Elderly patients or patients with cardiac disease.**

*Initial:* 12.5 to 25 mcg daily, increased gradually every 4 to 6 wk, as needed.

**Adults with severe long-standing hypothyroidism.**

*Initial:* 12.5 to 25 mcg daily with dosage adjusted in 12.5 to 25 mcg increments every 2 to 4 wk, as needed.

- *To treat acquired or congenital hypothyroidism in children*

### TABLETS

**Children age 12 and over in whom growth and puberty are incomplete.** 2 to 3 mcg/kg daily.

**Children ages 6 to 12.** 4 to 5 mcg/kg daily.

**Children ages 1 to 5.** 5 to 6 mcg/kg daily.

**Infants ages 6 to 12 months.** 6 to 8 mcg/kg daily.

**Infants ages 3 to 6 months.** 8 to 10 mcg daily.

**Infants and neonates birth to age 3 months.** 10 to 15 mcg/kg daily.

**Infants and neonates birth to age 3 months at risk for cardiac failure.** *Initial:* Highly individualized but less than 10 mcg daily with dosage increased every 4 to 6 wk, as needed.

## **CAPSULES (TIROSINT)**

**Children age 12 and over in whom growth and puberty are incomplete.** 2 to 3 mcg/kg daily.

**Children ages 6 to 12.** 4 to 5 mcg/kg daily.

- *As adjunct to surgery and radioiodine therapy in the management of thyrotropin-dependent well-differentiated thyroid cancer*

## **CAPSULES, TABLETS**

**Adults.** *Usual:* Greater than 2 mcg/kg daily but could be less.

- *To treat myxedema coma*

## **I.V. INJECTION**

**Adults.** *Initial as loading dose:* 300 to 500 mcg, followed by 50 to 100 mcg once daily until patient able to tolerate drug orally.

***DOSAGE ADJUSTMENT*** Dosage adjustment highly individualized according to patient's response and tolerance as well as age, degree of hypothyroidism present, general physical condition, and severity of cardiac risk factors. Dosage possibly increased during pregnancy.

For children at risk for hyperactivity, initial dosage reduced by 75% of normal dosage with dosage increased by 25% of the full recommended replacement dosage weekly until the full replacement dosage is reached.

Route	Onset	Peak	Duration
P.O.	3-5 days	3-4 wk	1-3 wk
I.V.	6-8 hr	24 hr	Unknown

## Mechanism of Action

Replaces endogenous thyroid hormone, which may exert its physiologic effects by controlling DNA transcription and protein synthesis. Levothyroxine has all the following actions of endogenous thyroid hormone. The drug:

- increases energy expenditure
- accelerates the rate of cellular oxidation, which stimulates body tissue growth, maturation, and metabolism
- regulates differentiation and proliferation of stem cells
- aids in myelination of nerves and development of synaptic processes in the nervous system
- regulates growth
- decreases blood and hepatic cholesterol concentrations
- enhances carbohydrate and protein metabolism, increasing gluconeogenesis and protein synthesis.

## Contraindications

Hypersensitivity to levothyroxine or its components,  
uncorrected adrenal insufficiency

## Interactions

## DRUGS

*5-fluorouracil, clofibrate, estrogens (oral), estrogen-containing oral contraceptives, heroin, methadone, mitotane, tamoxifen*: Possibly increased serum thyroxine-binding globulin (TBG) concentration

*aluminum- and magnesium-containing antacids, calcium carbonate, ccholestyramine, colestipol, colesevelam, ferrous sulfate, kayexalate, orlistat, proton pump inhibitors, sevelamer, simethicone, sucralfate*: Possibly decreased absorption and reduced effects of levothyroxine

*amiodarone, glucocorticoids*: Possibly hyperthyroidism from decreased peripheral conversion of T<sub>4</sub> to T<sub>3</sub>, leading to decreased T<sub>3</sub> levels

*anabolic steroids, androgens, asparaginase, glucocorticoids, slow-release nicotinic acid*: Possibly decreased serum TBG concentration

*beta blockers*: Possibly impaired action of beta blockers and decreased conversion of T<sub>4</sub> to triiodothyronine (T<sub>3</sub>)

*carbamazepine, fenamates, furosemide (greater than 80 mg IV), heparin, hydantoins, NSAIDs, salicylates (greater than 2 g/day)*: Transient increase in FT<sub>4</sub> followed by decreased serum T<sub>4</sub> and normal FT<sub>4</sub> and TSH concentrations with continued administration

*digoxin*: Reduced digoxin effects

*insulin, oral antidiabetic drugs*: Decreased effectiveness of these drugs

*ketamine*: Possibly marked hypertension and tachycardia

*oral anticoagulants*: Altered anticoagulant activity

*phenobarbital*: Reduces response to thyroxine decreasing effectiveness

*rifampin*: Accelerates metabolism of levothyroxine

*sympathomimetics*: Increased risk of coronary insufficiency in patients with coronary artery disease; increased effects of both drugs

*tetracyclic and tricyclic antidepressants*: Increased therapeutic and toxic effects of both drugs  
*tyrosine-kinase inhibitors*: Possible decreased effectiveness of levothyroxine leading to hypothyroidism

## **FOODS**

*cottonseed meal, dietary fiber, soybean flour (infant formula), walnuts*: Possibly decreased absorption of levothyroxine from GI tract  
*grapefruit juice*: Possible delayed absorption of levothyroxine and reduced bioavailability

## **Adverse Reactions**

**CNS**: Anxiety, craniosynostosis (infants with overtreatment), emotional lability, fatigue, fever, headache, heat intolerance, hyperactivity, insomnia, irritability, nervousness, **pseudotumor cerebri** (children), **seizures** (rare), somnolence, tremors

**CV**: Angina, **arrhythmias**, **cardiac arrest**, **heart failure**, increased blood pressure and pulse, **MI**, palpitations, tachycardia

**ENDO**: Hyperthyroidism (with over-replacement), **myxedema coma (with undertreatment)**, worsening of diabetic control

**GI**: Abdominal cramps or pain, diarrhea, dysphagia, elevated liver enzymes, increased appetite, nausea, vomiting

**GU**: Impaired fertility, menstrual irregularities

**MS**: Arthralgia, decreased bone mineral density (with over-replacement), premature closure of the epiphysis (children), muscle spasm or weakness, myalgia, slipped capital femoral epiphysis (children)

**RESP**: Dyspnea, wheezing

**SKIN:** Alopecia (transient), diaphoresis, flushing, pruritus, rash, urticaria

**Other:** **Angioedema**, serum sickness, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug is not known to cause fetal harm and should not be stopped during pregnancy.
- Be aware that pregnancy may increase dosage requirements.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that levothyroxin therapy is not to be used for treatment of obesity or for weight loss.
- Use levothyroxine cautiously in the elderly and patients with underlying cardiovascular disease. Know that levothyroxine should be started at a lower dose in these patients because overtreatment can increase cardiac contractility, cardiac wall thickness, and heart rate, which can precipitate angina or arrhythmias. Also use caution in patients with coronary artery disease undergoing surgery while receiving suppressive levothyroxin therapy and in patients receiving sympathomimetic drugs concurrently. Monitor for signs and symptoms of coronary insufficiency.
- Use caution when administering levothyroxine to children to avoid overtreatment or undertreatment. Be aware that overtreatment may cause craniosynostosis in infants, may adversely affect brain maturation, and may accelerate the bone age and result in premature epiphyseal closure, which will compromise stature for life. Undertreatment may cause adverse effects on intellectual development and linear growth of the child.

- Administer levothyroxine capsules or tablets as a single daily dose 30 to 60 minutes before breakfast. Capsules must be swallowed whole. If patient has difficulty swallowing or patient is an infant or small child, crush tablet and suspend in a small amount of water or food avoiding liquids that decrease absorption of levothyroxine, such as soybean infant formula. Once mixed, do not store the suspension.
- Give oral levothyroxine at least 4 hours before or after aluminum- or magnesium-containing antacids, bile acid sequestrants, calcium carbonate, cation exchange resins, cholestyramine, colestipol, ferrous sulfate, kayexalate, or sucralfate to prevent decreased drug absorption.
- Expect to give drug I.V. if patient can't take tablets.
- For I.V. use, reconstitute drug by adding 5 ml of normal saline solution.
- Monitor PT of patient who is receiving anticoagulants; she may require a dosage adjustment.
- Monitor blood glucose level of diabetic patient because drug may worsen glycemic control and result in increased antidiabetic agent or insulin requirement. Carefully monitor patient after starting, changing, or discontinuing levothyroxine.
- Expect patient to undergo thyroid function tests regularly during levothyroxine therapy. Monitor patient for signs and symptoms of over- or undertreatment with levothyroxine because drug has a narrow therapeutic index. Be aware that atrial fibrillation is the most common arrhythmia with levothyroxine overtreatment in the elderly.
- Keep in mind when interpreting TBG levels that many disorders and medications can decrease TBG concentration, causing a TBG deficiency.

## **PATIENT TEACHING**

- Inform patient that levothyroxine replaces a hormone that is normally produced by the thyroid gland and that she'll probably need to take drug for life.
- Instruct patient to take drug at least 30 minutes before breakfast because drug absorption is increased on an empty stomach and evening doses may cause insomnia.
- Emphasize the need to take levothyroxine with a full glass of water to avoid choking, gagging, having tablet stick in throat, and developing heartburn afterward.

- Instruct patient to separate antacids and calcium or iron supplements by at least 4 hours from levothyroxine doses.
- Inform patient that drug may require a few weeks to take effect.
- Advise patient not to stop drug or change dosage unless instructed by prescriber.
- Instruct patient to report signs of hyperthyroidism, such as chest pain, diarrhea, excessive sweating, fever, headache, heat intolerance, insomnia, irritability, leg cramps, nervousness, palpitations, weight loss, shortness of breath, tremors, and vomiting.
- Tell patient to notify prescriber if hives or rash develop during drug use.
- Inform patient that transient hair loss may occur during first few months of levothyroxine therapy.
- Instruct female patient of childbearing age to notify prescriber immediately if she becomes pregnant because levothyroxine dosage may have to be increased.

## **lidocaine hydrochloride**

**Alphacaine (CAN), Anestacon, DermaFlex, Dilocaine, L-Caine, Lidoderm, Xylocaine, Xylocard (CAN), Zingo**

### **Class and Category**

*Pharmacologic class:* Amide derivative

*Therapeutic class:* Class IB antiarrhythmic, local anesthetic

### **Indications and Dosages**

- *To treat ventricular arrhythmias occurring during cardiac manipulations; to treat life-threatening ventricular arrhythmias*

## **I.V. INFUSION AND INJECTION**

**Adults.** *Loading:* 50 to 100 mg (or 1 to 1.5 mg/kg), given at 25 to 50 mg/min. If desired response isn't achieved after 5 to 10 min, second dose of 25 to 50 mg (or 0.5 to 0.75 mg/kg) given every 5 to 10 min until maximum loading dose (300 mg in 1 hr) has been given. *Maintenance:* 20 to 50 mcg/kg/min (1 to 4 mg/min) by continuous infusion. Smaller bolus dose repeated 15 to 20 min after start of infusion if needed to maintain therapeutic blood level. *Maximum:* 300 mg (or 3 mg/kg) over 1 hr.

**Children.** *Loading:* 1 mg/kg (not to exceed 100 mg). If infusion is not initiated within 15 min of loading dose, bolus dose repeated. *Maintenance:* 20 to 50 mcg/kg/min by continuous infusion. *Maximum:* 3 mg/kg.

***DOSAGE ADJUSTMENT*** For patient receiving prolonged lidocaine therapy intravenously (24 hours), dosage reduced to one-half. For elderly patients loading dose and continuous infusion rate reduced. For patients with hepatic impairment or severe renal impairment (creatinine clearance estimated glomerular filtration rate less than 30 ml/min), maintenance infusion rate reduced.

- *To provide topical anesthesia for mucous membranes or skin*

## **FILM-FORMING GEL, JELLY, OR OINTMENT**

**Adults.** Thin layer applied to skin or mucous membranes as needed before procedure.

- *To provide pain relief postherpetic neuralgia*

## TRANSDERMAL PATCH (LIDODERM 5%)

**Adults.** 1 to 3 patches applied over most painful area only once for up to 12 hr within a 24-hr period.

- *To provide topical anesthesia before venous access procedures*

## POWDER (ZINGO)

**Adults and children ages 3 to 18.** 0.5 mg as a compressed gas application of powder to selected skin site 1 to 3 min before procedure.

Route	Onset	Peak	Duration
I.V.	45-90 sec	Immediate	10-20 min
Topical	2-5 min	Unknown	0.5-1 hr

## Mechanism of Action

Combines with fast sodium channels in myocardial cell membranes, which inhibits sodium influx into cells and decreases ventricular depolarization, as well as automaticity and excitability during diastole. Lidocaine also blocks nerve impulses by decreasing the permeability of neuronal membranes to sodium, which produces local anesthesia.

## Incompatibilities

Do not mix lidocaine with blood transfusions because of the possibility of hemolysis or pseudoagglutination. Also do not administer with solutions containing amphotericin, cephalazolin, or phenytoin because of precipitate formation.

## Contraindications

Adams–Stokes syndrome; hypersensitivity to lidocaine, amide anesthetics, or their components; severe heart block (without artificial pacemaker); Wolff–Parkinson–White syndrome

## Interactions

### DRUGS

*amiodarone, phenytoin, procainamide, propranolol, quinidine*: Additive cardiac effects possibly resulting in toxicity; antagonistic cardiac effects

*beta blockers, CYP1A2 inhibitors such as fluvoxamine, CYP3A4 inhibitors such as propofol, cimetidine*: Increased blood lidocaine level and risk of toxicity

*CYP1A2 inducers, CYP3A4 inducers*: Decreased blood lidocaine level with decreased effectiveness

*digoxin*: Increased toxicity

## Adverse Reactions

**CNS**: Agitation; anxiety; apprehension; confusion; difficulty speaking; disorientation; dizziness; drowsiness; euphoria; hallucinations; lethargy; light-headedness; **malignant hyperthermia**; paresthesia; **seizures**; sensation of cold, heat, or numbness; tremors; twitching; unconsciousness

**CV**: **Bradycardia, cardiac arrest, hypotension, new or worsening arrhythmias**, tachycardia

**EENT**: Blurred vision, diplopia, oral hypoesthesia, tinnitus

**GI**: Nausea, vomiting

**HEME**: **Methemoglobinemia**

**MS**: Dysarthria, muscle weakness, myalgia

**RESP**: **Respiratory arrest or depression**

**Other**: **Anaphylaxis**; other less severe hypersensitivity reactions; injection-site burning, irritation, petechiae,

redness, stinging, swelling, and tenderness; worsened pain

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Use caution in patients with severe hepatic or renal disease because accumulation of lidocaine may occur and lead to toxicity. Also, use caution in patients with any form of AV block, including AV block caused by digitalis toxicity, as well as in patients with hypovolemia and shock.
- Use caution when administering lidocaine to patients with compromised myocardial function because of risk of electrolyte disturbances or fluid overload.
- Observe for respiratory depression after bolus injection and during I.V. infusion of lidocaine.
- Keep life-support equipment and vasopressors nearby during I.V. use in case of respiratory depression or other reactions. Hypersensitivity reactions, including anaphylaxis, have occurred with lidocaine-containing solutions.
- Carefully check prefilled syringes before using. Use only syringes labeled “for cardiac arrhythmias” for I.V. administration.
- As ordered, titrate I.V. dose to minimum amount needed to prevent arrhythmias. If administration is controlled by a pumping device, stop pump before container runs dry because an air embolism may result.

Change intravenous administration apparatus at least once every 24 hours.

- During I.V. administration, place patient on cardiac monitor, as ordered, and closely observe her at all times. Monitor for prolonged PR interval, widening QRS complex, or worsening arrhythmias—possible signs of drug toxicity. If present, notify prescriber and expect to discontinue lidocaine therapy immediately. Although infrequent, also monitor her for hypersensitivity reactions that can be as severe as anaphylaxis following lidocaine administration. If anaphylaxis occurs, discontinue drug, notify prescriber, and provide supportive care.
- Check blood drug level, as ordered. Therapeutic level is 2 to 5 mcg/ml.
- If signs of toxicity, such as dizziness, occur, notify prescriber and expect to discontinue or slow infusion.
- Monitor for malignant hyperthermia. If present, stop lidocaine administration immediately, notify prescriber, and provide therapeutic countermeasures, as indicated and ordered.
- Apply lidocaine jelly or ointment to gauze or bandage before applying to skin.
- Monitor vital signs as well as BUN and serum creatinine and electrolyte levels during and after therapy.

## **PATIENT TEACHING**

- Inform patient who receives lidocaine as an anesthetic that she'll feel numbness.
- Advise patient to report difficulty speaking, dizziness, injection-site pain, nausea, numbness or tingling, and vision changes.
- Caution patient to keep lidocaine topical preparations and patches out of reach of children and pets.
- Tell patient to wash hands thoroughly after handling lidocaine topical forms or patch and to avoid getting drug in eyes.
- Remind patient using patches to store them in their sealed envelopes until needed and to apply immediately after removing from the envelope. Tell patient to remove patch if burning or irritation occurs at the site and not to reapply until irritation is gone.
- Tell patient to fold used patches so that the adhesive side sticks to itself and discard where children or pets cannot get to them.

- Warn patient prescribed a lidocaine patch not to place external heat sources, such as electric blanket or heating pad, on it while wearing it, because heat may cause the drug to be absorbed faster, increasing the risk of adverse effects.
- Instruct women of childbearing age to alert prescriber if pregnancy is suspected or known, because lidocaine may cross the placental barrier. Inform mothers wishing to breastfeed that lidocaine is present in breast milk and to discuss wisdom of breastfeeding with prescriber before doing so.

## linacotide

### Linzess

## Class and Category

*Pharmacologic class:* Guanylate cyclase-C agonist

*Therapeutic class:* Bowel stimulator

## Indications and Dosages

➤ *To treat irritable bowel syndrome with constipation*

### CAPSULES

**Adults.** 290 mcg once daily on an empty stomach, at least 30 min prior to the first meal of the day.

➤ *To treat chronic, idiopathic constipation*

### CAPSULES

**Adults.** 72 or 145 mcg once daily on an empty stomach, at least 30 min prior to the first meal of the day.

# Mechanism of Action

Acts locally on the luminal surface of the intestinal epithelium through activation of guanylate cyclase-C, which increases both extracellular and intracellular concentrations of cyclic guanosine monophosphate (cGMP). Elevation in intracellular cGMP stimulates secretion of bicarbonate and chloride into the intestinal lumen, which increases intestinal fluid and accelerates GI transit to relieve constipation. Increased extracellular cGMP decreases the activity of pain-sensing nerves, resulting in a reduction of intestinal pain present with constipation and irritable bowel syndrome.

# Contraindications

Hypersensitivity to linaclotide or its components, known or suspected mechanical gastrointestinal obstruction, pediatric patients under 6 years of age

# Interactions

## DRUGS

None reported

# Adverse Reactions

**CNS:** Fatigue, headache

**EENT:** Sinusitis

**GI:** Abdominal distention or pain, defecation urgency, diarrhea (may become severe), dyspepsia, fecal incontinence, flatulence, gastroesophageal reflux, hematochezia, **melena**, **rectal hemorrhage**, viral gastroenteritis, vomiting

**RESP:** Upper respiratory infection

**SKIN:** Urticaria

**Other:** Hypersensitivity reactions

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug has the potential to cause serious adverse reactions in the breastfed infant.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that although linaclotide is contraindicated in children under 6 years of age, it also is not recommended to be given to children between the ages of 6 and 17 years.
- Monitor patient for diarrhea that may become severe. If severe diarrhea occurs, assess patient for dizziness, electrolyte abnormalities (hypokalemia and hyponatremia), hypotension, and syncope. Notify prescriber if diarrhea occurs. Expect to withhold drug. Also know that if severe, patient may require hospitalization and intravenous fluid administration.
- Open capsules for patients having difficulty swallowing capsules and sprinkle contents on 1 teaspoon of applesauce or mix with 1 ounce of room-temperature bottled water (swirl beads and water for at least 20 seconds) just prior to administration. Linaclotide can also be administered through a gastrostomy or nasogastric tube by mixing first with 1 ounce

room-temperature bottled water (swirling beads and water for at least 20 seconds) immediately before administration.

## PATIENT TEACHING

- Instruct patient to swallow the capsules whole and to avoid breaking the capsule apart or chewing it. However, if patient has difficulty swallowing capsules, tell patient to open capsule and mix with either 1 teaspoon of applesauce or 1 ounce of room-temperature bottled water (swirl beads in the for at least 20 seconds) immediately before ingesting.
- Tell patient that linacotide is to be taken on an empty stomach 30 minutes before the first meal of the day.
- Advise patient to stop taking linacotide if severe diarrhea occurs and to contact prescriber immediately because hospitalization and intravenous fluid replacement may be necessary.
- Instruct patient to store linacotide out of the reach of children.

# linagliptin

## Tradjenta

## Class and Category

*Pharmacologic class:* Dipeptidyl peptidase-4 (DDP-4) enzyme inhibitor

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to improve glycemic control in type 2 diabetes mellitus*

## TABLETS

**Adults.** 5 mg once daily.

**DOSAGE ADJUSTMENT** For patients taking a supplemental oral hypoglycemic agent or insulin, dosage may need to be reduced.

## Mechanism of Action

Inhibits the enzyme, dipeptidyl peptidase-4, that degrades incretin hormones responsible for glucose elevation. This allows levels of incretin hormones to rise, stimulating the release of insulin in a glucose-dependent manner while decreasing the glucagon level in the blood. In addition, glucagon secretion from pancreatic alpha cells is reduced, resulting in a reduction in the amount of glucose released by the liver. These combined actions reduce blood glucose levels, thereby improving glycemic control in type 2 diabetes.

## Contraindications

Hypersensitivity to linagliptin or its components

## Interactions

### DRUGS

*CYP3A4 or P-gp inducers (strong) such as rifampin:*

Decreased linagliptin effectiveness

*insulin, sulfonylureas:* Increased risk of hypoglycemia

## Adverse Reactions

**CNS:** Headache

**CV:** Hyperlipidemia, hypertriglyceridemia

**EENT:** Mouth ulceration, nasopharyngitis, stomatitis

**ENDO:** Hypoglycemia

**GI:** Acute pancreatitis, constipation, diarrhea, elevated lipase level

**GU:** UTI

**MS:** Arthralgia (may be disabling and severe); back, extremity, or joint pain; myalgia; rhabdomyolysis

**RESP:** Bronchial hyperreactivity, cough

**SKIN:** Bullous pemphigoid, localized skin exfoliation, rash, urticaria

**Other:** Anaphylaxis, angioedema, elevated uric acid, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Know that linagliptin's hypersensitivity may be exhibited through serious adverse reactions such as anaphylaxis, angioedema, bronchial hyperreactivity, exfoliative skin conditions, or urticaria. Monitor patient closely for hypersensitivity reactions. If present, withhold drug immediately, notify prescriber, and be prepared to administer emergency care, as ordered.

- Be aware that heart failure has been linked to two other drugs in the same class as linagliptin. Use caution when administering linagliptin, especially to patients with a prior history of heart failure or renal impairment. Monitor patient for signs and symptoms of heart failure and report any to prescriber immediately.
- Monitor patient closely for hypoglycemia, especially if another antidiabetic drug, such as insulin or a sulfonylurea is used concomitantly. If signs and symptoms of hypoglycemia occur, check patient's blood glucose level. If confirmed, administer 15 g of an oral rapid-acting carbohydrate. After 15 minutes, repeat blood glucose and, if needed, administer 15 g of an oral rapid-acting carbohydrate again. (Administer glucagon 1 mg parenterally, as ordered; if patient is unresponsive, and repeat dose in 15 minutes, if needed.) Notify prescriber of incident, as dosage of the other antidiabetic drug may need to be reduced.
- Monitor the patient's blood glucose level routinely to determine response to drug. Expect to check the patient's glycosylated hemoglobin every 3 to 6 months or as ordered to evaluate long-term blood glucose control.
- Monitor patient for signs and symptoms of pancreatitis such as abdominal pain, fever, nausea, sweating, and vomiting. Notify prescriber if present, and expect drug to be discontinued, as acute pancreatitis may become life-threatening.

## **PATIENT TEACHING**

- Advise patient if a dose is missed he should not double up on the next dose.
- Urge patient to report evidence of hypoglycemia, such as anxiety, confusion, dizziness, excessive sweating, headache, and nausea.
- Encourage patient to carry hard candy or other simple sugars to treat mild hypoglycemia.
- Urge patient to carry identification indicating that he has diabetes.
- Teach patient how to monitor his blood glucose level.
- Instruct patient about diet, exercise, foot care, hygiene, signs of hyperglycemia and hypoglycemia, and ways to avoid infection.
- Tell patient to stop drug if he experiences signs and symptoms of an allergic reaction such as difficulty breathing, hives, rash, or swelling of face or skin or signs and symptoms of acute pancreatitis such as persistent severe abdominal pain radiating to the back, which may or may

not be accompanied by vomiting, and to seek medical attention immediately.

- Review signs and symptoms of heart failure with patient such as difficulty breathing; swelling or fluid retention, especially in ankles, feet, or legs; unusual tiredness; or fast weight gain. Tell patient to report any such symptoms immediately.
- Inform patient that disabling and severe arthralgia may occur with linezolid therapy beginning within a day of starting therapy or years later. Patient should notify prescriber if severe joint pain occurs.
- Advise patient to report blisters or erosions that occur on his skin to prescriber.

## linezolid

### Zyvox

## Class and Category

*Pharmacologic class:* Oxazolidinone

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat vancomycin-resistant Enterococcus faecium infections, including bacteremia*

### ORAL SUSPENSION, TABLETS, I.V. INFUSION

**Adults and adolescents.** 600 mg every 12 hr for 14 to 28 days. I.V. infused over 30 min to 2 hr.

**Neonates age 7 days and over, infants, and children.** 10 mg/kg every 8 hr for 14 to 28 days. I.V. infused over 30 min to 2 hr.

**Neonates younger than 7 days.** 10 mg/kg every 12 hr, increased to every 8 hr when neonate is 7 days old. Given for 14 to 28 days. I.V. infused over 30 min to 2 hr.

- *To treat nosocomial pneumonia caused by Staphylococcus aureus (methicillin-susceptible and resistant strains) or Streptococcus pneumoniae (penicillin-susceptible strains only) and community-acquired pneumonia, including accompanying bacteremia, caused by S. aureus (methicillin-susceptible strains only) or S. pneumoniae (penicillin-susceptible strains only); to treat complicated skin and soft-tissue infections, including diabetic foot infections without concomitant osteomyelitis, caused by S. aureus (methicillin-susceptible and resistant strains), Streptococcus agalactiae, or Streptococcus pyogenes*

## **ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults and adolescents.** 600 mg every 12 hr for 10 to 14 days. I.V. infused over 30 min to 2 hr.

**Neonates age 7 days or older, infants, and children.**

10 mg/kg every 8 hr for 10 to 14 days. I.V. infused over 30 min to 2 hr.

**Neonates younger than 7 days.** 10 mg/kg every 12 hr, increased to every 8 hr when neonate is 7 days old. Given for 10 to 14 days. I.V. infused over 30 min to 2 hr.

- *To treat uncomplicated skin and soft-tissue infections caused by S. aureus (methicillin-susceptible strains only) or S. pyogenes*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 400 mg every 12 hr for 10 to 14 days.

**Adolescents.** 600 mg every 12 hr for 10 to 14 days.

**Children age 5 to 11.** 10 mg/kg every 12 hr for 10 to 14 days.

**Neonates age 7 days and over, infants, and children to age 5.** 10 mg/kg every 8 hr.

**Neonates younger than 7 days.** 10 mg/kg every 12 hr, increased to every 8 hr when neonate is 7 days old. Given for 10 to 14 days.

## Incompatibilities

Don't add other drugs to linezolid solution. Don't infuse linezolid in same I.V. line as amphotericin B, chlorpromazine hydrochloride, cotrimoxazole, diazepam, erythromycin lactobionate, pentamidine isethionate, or phenytoin sodium because these drugs are physically incompatible. Don't infuse linezolid with ceftriaxone sodium because these drugs are chemically incompatible.

## Contraindications

Hypersensitivity to linezolid or its components, use within 14 days of an MAO inhibitor

## Interactions

### DRUGS

*bupropion, buspirone, meperidine, serotonergics, tricyclic antidepressants, triptans:* Possibly serotonin syndrome  
*dopaminergic agents (dobutamine, dopamine), sympathomimetic agents (pseudoephedrine), vasopressor agents (epinephrine, norepinephrine):* Increased risk of altered blood pressure.

*MAO inhibitors:* Increased risk of life-threatening adverse effects

## FOODS

*tyramine-containing beverages and foods:* Possibly hypertension

### Mechanism of Action

Linezolid inhibits bacterial protein synthesis by interfering with translation of ribonucleic acid (RNA) to protein. In bacteria, protein synthesis begins with binding of a 30S ribosomal subunit and a 50S ribosomal subunit to a messenger RNA (mRNA) molecule to form a 70S initiation complex. The 50S ribosomal subunit consists of 23S ribosomal RNA (rRNA) and other ribosomal subunits. Then translation begins. Transfer RNA (tRNA) attaches to the 50S subunit and brings specific amino acids into place. As the tRNA and amino acids fall into place, they are joined together by peptide bonds and elongate to form a polypeptide chain, as shown below left. This chain eventually combines with other polypeptide chains to form a complete protein molecule. After translation is complete, the ribosomal subunits fall away and are ready to combine with more mRNA to start the translation process over again.

Linezolid binds to a site on the bacterial 23S rRNA of the 50S subunit. This action prevents formation of a functional 70S initiation complex, an essential component of the bacterial translation. Without proper protein production, as shown below right, susceptible bacteria are unable to multiply. Linezolid is bactericidal against most streptococci and bacteriostatic against staphylococci and enterococci.

Description

## Adverse Reactions

**CNS:** Dizziness, fever, headache, insomnia, peripheral neuropathy, **seizures**, **serotonin syndrome**, vertigo

**CV:** Hypertension

**EENT:** Optic neuropathy with possible loss of vision, oral candidiasis, taste alteration, tooth or tongue discoloration

**GI:** Abdominal pain, constipation, diarrhea, elevated liver enzymes, indigestion, nausea, **pseudomembranous colitis**, vomiting

**GU:** Vaginal candidiasis

**HEME:** Anemia, eosinophilia, **leukopenia**, **pancytopenia**, **sideroblastic anemia**, **thrombocytopenia**

**SKIN:** Bullous dermatitis, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**, **angioedema**, fungal infections, **lactic acidosis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Obtain body tissue and fluid specimens for culture and sensitivity tests, as ordered, before giving first dose of linezolid. Expect to start drug before test results are known.
- Be aware that linezolid shouldn't be used to treat catheter-related bloodstream infections, catheter-site infections, or infections caused by gram-negative bacteria because the risk of death is higher in these infections.
- Infuse I.V. solution over 30 to 120 minutes with D<sub>5</sub>W, normal saline solution, or lactated Ringer's solution.

**WARNING** Monitor CBC weekly, as ordered, to detect or track worsening myelosuppression in patients who need more than 2 weeks of therapy, who have preexisting myelosuppression and are receiving drugs that produce bone marrow suppression, or who have chronic infection and are receiving or have received antibiotic therapy.

- Notify prescriber if patient develops visual impairment that suggests optic neuropathy, such as blurred vision, changes in color vision or visual acuity, lost vision, or visual field defect. If optic or peripheral neuropathy develops, the drug may need to be stopped.
- Know that if patient takes a dopaminergic agent, sympathomimetic agent, or vasopressor agent, monitor blood pressure closely; if monitoring isn't possible, know that linezolid shouldn't be prescribed.

- Be aware that while linezolid should not be given to patients receiving serotonergic drugs, there are some conditions that may be life-threatening and require the use of linezolid, such as the presence of vancomycin-resistant *Enterococcus faecium* (VRE) or infections such as nosocomial pneumonia and complicated skin and skin structure infections, including those caused by *methicillin-resistant Staphylococcus aureus* (MRSA). If patient takes buspirone, meperidine, or a serotonergic or tricyclic antidepressant, watch closely for signs and symptoms of serotonin syndrome; if monitoring isn't possible, know that linezolid shouldn't be prescribed.
- Assess bowel pattern daily. Also watch for secondary infection, including oral candidiasis and profuse, watery diarrhea.
- Monitor patient with diabetes who is also taking antidiabetic medication because hypoglycemia has been linked to linezolid use in these patients. If hypoglycemia occurs, treat appropriately and notify prescriber, as the dosage of the antidiabetic medication may have to be decreased.

## PATIENT TEACHING

- Caution patient with phenylketonuria that oral suspension contains phenylalanine and that he should receive tablets instead.
- Tell patient to store oral suspension at room temperature and to discard any unused portion after 21 days.
- Advise patient not to take OTC cold remedies without consulting prescriber because medications that contain propanolamine or pseudoephedrine may cause or worsen hypertension.
- Instruct patient to avoid beverages and foods that contain large amounts of tyramine, including aged cheese, air-dried or fermented meats, protein-rich foods that have been stored for long periods or poorly refrigerated, red wines, soy sauce, and tap beers.
- Instruct patient to notify prescriber at once about severe diarrhea, even up to 2 months after linezolid therapy has ended, because additional treatment may be needed.
- Tell patient to report changes in limb sensation (such as numbness, pins and needles, or tingling) or vision changes because drug may have to be stopped. Also, tell patient to notify prescriber immediately if persistent, severe, or unusual signs and symptoms develop.
- Reassure patient with tooth discoloration that professional dental cleaning can restore tooth color.

- Advise diabetic patients prescribed antidiabetic medications to monitor their blood glucose closely and be prepared to treat hypoglycemia if it should occur. If present, tell patient to notify prescriber as a dosage adjustment may be required in his antidiabetic medication.

## **liraglutide**

### **Saxenda, Victoza**

## **Class and Category**

*Pharmacologic class:* Glucagon-like peptide-1 receptor agonist

*Therapeutic class:* Antidiabetic

## **Indications and Dosages**

- *To improve glycemic control as an adjunct to diet and exercise in patients with type 2 diabetes mellitus; to reduce risk of major adverse cardiovascular events such as CVA or MI in patients with type 2 diabetes mellitus and established cardiovascular disease*

### **SUBCUTANEOUS INJECTION (VICTOZA)**

**Adults and children age 10 and over.** *Initial:* 0.6 mg daily for 1 wk, then increased to 1.2 mg daily. *Maximum:* 1.8 mg daily.

- *Adjunct for chronic weight management in patients with an initial body mass index of 30 kg/m<sup>2</sup> or greater, or 27 kg/m<sup>2</sup> or greater in the presence of at least one*

*weight-related comorbid condition such as dyslipidemia, hypertension, or type 2 diabetes mellitus*

## **SUBCUTANEOUS INJECTION (SAXENDA)**

**Adults.** *Initial:* 0.6 mg daily for wk 1, increased to 1.2 mg daily for wk 2, increased to 1.8 mg daily for wk 3, increased to 2.4 mg daily for wk 4, and increased to 3 mg daily for wk 5 and onward. *Maintenance:* 3 mg daily.

Route	Onset	Peak	Duration
SubQ	Unknown	8–12 hr	Unknown

## **Mechanism of Action**

Activates the glucagon-like peptide-1 site on pancreatic beta cells, which increases intracellular cyclic AMP, which increases insulin release when blood glucose level is elevated. In addition, because glucagon and insulin levels occur in an inverse relationship to plasma glucose level, increased insulin level will decrease glucagon level, which inhibits glucagon stimulation of the liver that increases plasma glucose level. Although its exact mechanism is unclear, liraglutide also delays gastric emptying, which helps prevent a sudden rise in plasma glucose level after eating. Together these actions work to lower plasma glucose level.

Binds to the glucagon-like peptide-1 receptor and activates it to regulate appetite and calorie intake, resulting in weight loss.

## **Contraindications**

Family or personal history of medullary thyroid cancer, hypersensitivity to liraglutide or its components, pregnancy

(Saxenda), presence of multiple endocrine neoplasia syndrome type 2

## Interactions

### DRUGS

*oral hypoglycemic agents such as sulfonylureas:* Increased risk of hypoglycemia

*orally administered drugs:* Possibly decreased absorption of these drugs

## Adverse Reactions

**CNS:** Anxiety, asthenia, dizziness, fatigue, headache, insomnia, malaise, **suicidal ideation**

**CV:** Edema, hypertension, **hypotension**, palpitations

**EENT:** Dry mouth, nasopharyngitis, sinusitis, taste distortion

**ENDO:** Elevated calcitonin levels, **hypoglycemia**, **thyroid C-cell hyperplasia**, **thyroid cancer**

**GI:** Abdominal distention or pain, **acute pancreatitis**, anorexia, cholecystitis, cholelithiasis, constipation, diarrhea, dyspepsia, elevated liver or pancreatic enzymes, eructation, flatulence, gastroenteritis, **hemorrhagic and necrotizing pancreatitis**, **hepatitis**, hyperbilirubinemia, jaundice, nausea, slowed gastric emptying, vomiting

**GU:** **Acute renal failure**, elevated serum creatinine level, UTI, **worsening of chronic renal failure**

**MS:** Back pain

**RESP:** Dyspnea, upper respiratory tract infection

**SKIN:** Pruritus, rash, urticaria

**Other:** **Anaphylaxis**; **angioedema**; antilraglutide antibodies; dehydration; influenza-like symptoms; injection-site reaction including erythema, pruritus, rash

# Childbearing Considerations

## PREGNANCY

- It is not known if Victoza brand of drug causes fetal harm, but animal studies suggest it may.
- Saxenda brand of drug is contraindicated in pregnancy because weight loss offers no benefit to a pregnant women and may result in fetal harm.
- Use Victoza with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that liraglutide isn't recommended as first-line therapy for patients with type 2 diabetes mellitus not well controlled with diet and exercise. It also isn't a substitute for insulin therapy. Saxenda brand shouldn't be given with insulin, nor should it be combined with other products intended for weight loss, including herbal preparations, over-the-counter products, or prescription drugs.
- Know that liraglutide shouldn't be given to a patient with a history of thyroid C-cell tumors, including medullary thyroid carcinoma, or to patients with multiple endocrine neoplasia syndrome type 2 because drug may stimulate tumor growth.
- Use liraglutide cautiously in patients with a history of pancreatitis because drug can cause pancreatitis, in patients with impaired hepatic function because drug effects in these patients are unknown, and in patients with renal dysfunction because liraglutide may adversely affect renal function.
- Be aware that dosage of liraglutide given during first week of therapy to lower blood glucose level isn't enough to provide glycemic control, but is given to minimize adverse effects when dosage is increased.

- Monitor patient closely for signs and symptoms of a hypersensitivity reaction that may become serious, especially in patients with a history of angioedema to other medications. If any hypersensitivity reaction occurs, discontinue liraglutide and notify the prescriber.
- Monitor patient's fluid intake, especially if gastrointestinal dysfunction occurs, because dehydration can lead to renal dysfunction that can become severe enough to require dialysis.
- Monitor patient's serum calcitonin levels, as indicated. Be aware that elevations occur more often when liraglutide dosage is 1.8 mg daily.
- Monitor patient for pancreatitis, especially when therapy starts or dosage increases. Report persistent severe abdominal pain; it may radiate to the back and may be accompanied by vomiting. If pancreatitis is confirmed, expect to stop drug and know that it should not be restarted after episode has been resolved.
- Also monitor patient for acute gallbladder disease. Risk is increased in patients who experience a rapid or substantial weight loss, although it may also occur in patients who have lost weight more slowly or less significantly. Notify prescriber if signs and symptoms occur and expect diagnostic testing to be performed.
- Monitor patient for hypoglycemia, especially if he takes another antidiabetic, such as a sulfonylurea. Know that the risk of hypoglycemia is higher in children 10 years and older regardless of concomitant antidiabetic therapies. Report any episode of hypoglycemia because dosage of other antidiabetic may need adjustment. Treat hypoglycemia with a glucose-containing beverage or food, or give glucagon, as ordered, to raise blood glucose level.
- Monitor patient's blood glucose level and hemoglobin A<sub>1C</sub> regularly, as ordered, to assess effectiveness of drug when used to treat diabetes mellitus.
- Monitor effectiveness of all other oral drugs because liraglutide slows gastric emptying and may impair their absorption. Alert prescriber to any concerns.
- Be aware that if more than 3 days has elapsed since the last liraglutide dose, the drug should be reinitiated at the initial dose of 0.6 mg.
- Monitor patient closely for suicidal ideation such as depression, or unusual changes in behavior or mood. If patient becomes suicidal, take safety precautions immediately, discontinue liraglutide therapy, as ordered, and notify prescriber.

## **PATIENT TEACHING**

- Teach patient how to use prefilled multidose pen and how to give a subcutaneous injection. Explain that he'll need to inject drug daily but that he can do it at any time of day, independent of meals. Tell patient to inject drug into his abdomen, thigh, or upper arm and to rotate sites to minimize injection-site reactions. Warn patient not to share his pen with anyone.
- Instruct patient to maintain an adequate fluid intake, as dehydration may cause kidney dysfunction.
- Advise patient of possible risk of medullary thyroid cancer or multiple endocrine neoplasia syndrome type 2 and the need to report any symptoms, such as dysphagia, dyspnea, a neck mass, or persistent hoarseness.
- Tell caregivers to monitor patient closely for depression or changes in behavior or mood. If suicidal, have them take safety precautions, stop the drug, and seek emergency medical help for patient.
- Emphasize that liraglutide therapy (Victoza brand) isn't a substitute for diet and exercise when used to treat diabetes mellitus but is used to enhance the effectiveness of these measures. However, alert patient that hypoglycemia can occur with drug use. Review signs and symptoms of low blood sugar with patient and appropriate treatment.
- Instruct patient to discontinue drug immediately and seek emergency care if he experiences a serious hypersensitivity reaction, such as difficulty breathing, feeling acutely ill, or swelling of the face or throat area.
- Inform patient that drug may increase risk for gallbladder disease. If abdominal pain, nausea, and vomiting occur, instruct patient to notify prescriber. Also, tell patient to report yellowing of skin or white of the eye along with gastrointestinal signs and symptoms to prescriber.
- Inform patient that drug may increase risk for acute pancreatitis. Tell patient to report persistent severe abdominal pain that may radiate to the back and may be accompanied by vomiting and to stop taking drug.
- Instruct female patients prescribed Saxenda to notify prescriber immediately if pregnancy is suspected or occurs, as drug will have to be discontinued.
- Have patient monitor her weight to assess effectiveness of drug (Saxenda) when prescribed for weight management. Tell patient that Saxenda used for weight loss must be discontinued if she has not achieved a 4% weight loss by 16 weeks.
- Tell patient prescribed Saxenda brand of drug that it should not be given with insulin, nor should it be combined with other products intended for

weight loss, including herbal preparations, over-the-counter products, and prescription drugs.

- Alert women that liraglutide does have an effect on preexisting breast neoplasia that may increase risk of breast cancer. In addition, inform all patients that there may be an increase in the development of colorectal neoplasms. Encourage all patients to have cancer screenings done as recommended by their doctor.
- Advise patient not to share her pen with another person, even if the needle is changed, because of an increased risk of transmitting an infection.

## lisdexamfetamine dimesylate

**Vyvanse**

### Class, Category, and Schedule

*Pharmacologic class:* Amphetamine

*Therapeutic class:* CNS stimulant

*Controlled substance schedule:* II

### Indications and Dosages

- *To treat attention deficit hyperactivity disorder (ADHD)*

#### **CAPSULES**

**Adults, adolescents, and children age 6 and over.**

*Initial:* 30 mg once daily in the morning, increased as

needed in increments of 10 or 20 mg daily every wk.  
*Maximum:* 70 mg daily.

➤ *To treat moderate to severe binge eating disorder*

## CAPSULES

**Adults.** *Initial:* 30 mg once daily, increased as needed in increments of 20 mg weekly to reach target dosage of 50 to 70 mg/day. *Maximum:* 70 mg daily.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment (GFR from 15 ml/min to less than 30 ml/min), maximum dose is limited to 50 mg daily. For patients with end-stage renal disease (GFR less than 15 ml/min), maximum dose is limited to 30 mg daily. For patients taking agents that alter urinary pH, dosage adjustments are individualized.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

## Mechanism of Action

Produces CNS stimulant effects, probably by facilitating release and blocking reuptake of norepinephrine at adrenergic nerve terminals and by stimulating alpha and beta receptors in peripheral nervous system. The drug also releases and blocks reuptake of dopamine in limbic regions of brain. These actions cause decreased motor restlessness and increased alertness. Lisdexamfetamine's action in the treatment of binge eating is unknown.

## Contraindications

Hypersensitivity, or idiosyncratic reaction to lisdexamfetamine, other sympathomimetic amines, or their

components; MAO inhibitor therapy including intravenous methylene blue and linezolid within 14 days

## Interactions

### DRUGS

*acidifying agents (urinary) such as ammonium chloride, sodium acid phosphate:* Decreased blood level and effects of lisdexamfetamine

*alkalinizing agents (urinary) such as acetazolamide, some thiazides:* Increased blood level and effects of lisdexamfetamine

*buspirone, fentanyl, lithium, MAO inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, St. John's wort, tricyclic*

*antidepressants, triptans, tryptophan:* Increased risk of serotonin syndrome

*CYP2D6 inhibitors such as fluoxetine, paroxetine, quinidine, ritonavir:* Increased exposure to dextroamphetamine; increase risk of serotonin syndrome

*MAO inhibitors:* Potentiated effects of lisdexamfetamine, possibly hypertensive crisis

*tricyclic antidepressants:* Possibly increased antidepressant effects and cardiovascular effects can be potentiated

## Adverse Reactions

**CNS:** Affect lability, aggression, agitation, anxiety, depression, dizziness, dyskinesia, dysphoria, energy increase, euphoria, fever, hallucinations, headache, insomnia, irritability, jittery feeling, mania, mood swings, nightmare, paranoia, psychomotor hyperactivity, psychotic episodes, restlessness, **seizures**, **serotonin syndrome**, somnolence, tics, tremor

**CV:** **Cardiomyopathy**, chest pain, hypertension, palpitations, peripheral vasculopathy, including Raynaud's phenomenon, tachycardia, ventricular hypertrophy  
**EENT:** Blurred vision, diplopia, dry mouth, mydriasis, oropharyngeal pain, taste alterations, teeth grinding, visual accommodation difficulties  
**ENDO:** Long-term growth suppression  
**GI:** Anorexia, constipation, diarrhea, **hepatitis**, nausea, upper abdominal pain, vomiting  
**GU:** Decreased libido, erectile dysfunction, frequent or prolonged erections, priapism, UTI  
**MS:** **Rhabdomyolysis**  
**RESP:** Dyspnea  
**SKIN:** Alopecia, diaphoresis, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, uncontrolled picking at skin, urticaria  
**Other:** **Anaphylaxis**, **angioedema**, physical or psychological dependence, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm because as an amphetamine, vasoconstriction occurs, which may decrease placental perfusion.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Be aware that drug can stimulate uterine contractions increasing the risk of premature delivery.
- Infants born to mothers taking amphetamines should be monitored for symptoms of withdrawal upon birth, such as agitation, excessive drowsiness, feeding difficulties, and irritability.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug use.

## Nursing Considerations

**WARNING** Keep in mind lisdexamfetamine shouldn't be given to patients with cardiac abnormalities (structural), cardiomyopathy, or other serious heart problems or rhythm abnormalities because even usual CNS-stimulant dosages increase risk of sudden death in patients with these conditions.

- Use lisdexamfetamine cautiously in patients with heart failure, hypertension, recent MI, or ventricular arrhythmia because drug may increase blood pressure and worsen these conditions.
- Know that patient should be screened for psychiatric risk factors such as a family or personal history of bipolar disorder, depression, or suicidal ideation because lisdexamfetamine may cause psychiatric adverse reactions. Monitor patients with bipolar disorder for mania.
- Monitor patient's blood pressure closely; stimulant drugs such as lisdexamfetamine may increase it.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of lisdexamfetamine. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. If symptoms occur, notify prescriber immediately, expect drug to be discontinued, and provide supportive care.

- Know that chest pain or fainting should be reported to prescriber immediately.

- Monitor patients with bipolar illness, a history of aggression or hostility or psychosis; CNS stimulation may worsen symptoms.
- Assess growth pattern in pediatric patients because stimulants such as lisdexamfetamine may suppress growth. If so, notify prescriber and expect therapy to be halted.
- Know that if patient has a history of seizures or EEG abnormality, watch for seizure activity because stimulants may lower seizure threshold. Rarely, lisdexamfetamine may cause seizures in a patient with no history of them. Take seizure precautions in all patients, and notify prescriber if a seizure occurs. Expect to discontinue lisdexamfetamine, as prescribed.
- Take safety precautions because stimulants may alter accommodation and cause blurred vision. Although these effects haven't been reported with lisdexamfetamine, the drug is a known stimulant.
- Be aware that therapy may be stopped temporarily to assess continued need for it, as evidenced by a return of attention deficit and hyperactivity.
- Know that lisdexamfetamine can cause a significant elevation in plasma corticosteroid levels, especially in the evening, which may interfere with urinary steroid determinations.

## PATIENT TEACHING

- Warn patient or caregiver that drug must be taken exactly as prescribed and dosage increased only at prescriber's instruction because drug can be abused or lead to dependence.
- Instruct patient or caregiver that capsule may be opened and contents dissolved in a glass of orange juice or water and drunk immediately. Alternatively, the contents of the capsule may be mixed with yogurt until completely dispersed; the entire mixture must be consumed immediately.
- Tell patient or caregiver that drug should only be taken in the morning because taking it later in the day may cause insomnia.
- Tell patient with symptoms such as chest pain or fainting to contact prescriber immediately.

**WARNING** Instruct patient to tell all prescribers about lisdexamfetamine therapy, as serious drug interactions can occur. Stress importance of seeking immediate medical care if persistent, severe, or unusual adverse reactions occur.

- Advise patient or caregiver to report any symptoms that suggest heart disease, such as exertional chest pain or unexplained syncope.
- Urge patient to avoid hazardous activities until drug effects are known.
- Warn male patients and parents of male children that painful or prolonged penile erections may occur while taking the drug, especially after a dose increase or during a period of drug withdrawal. In the event this happens, immediate medical attention should be sought.
- Instruct patient or parents to monitor fingers and toes for soft tissue breakdown and/or ulceration. If noticed, prescriber should be notified. Reassure patient that signs and symptoms generally improve after the dose is reduced or drug is discontinued.
- Tell female patient of childbearing age to notify prescriber if pregnancy is suspected or occurs. Also inform women wanting to breastfeed that breastfeeding is not recommended during lisdexamfetamine therapy.

## lisinopril

**Prinivil, Qbrelis, Zestril**

### Class and Category

*Pharmacologic class:* Angiotensin-converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive

### Indications and Dosages

➤ *To treat hypertension*

#### ORAL SUSPENSION, TABLETS

**Adults.** *Initial:* 10 mg daily. *Maintenance:* 20 to 40 mg daily. *Maximum:* 80 mg daily.

**Children age 6 and over with a GFR of at least 30 ml/min.** *Initial:* 0.07 mg/kg (maximum 5 mg) daily, adjusted according to blood pressure. *Maximum:* 0.61 mg/kg or 40 mg daily.

- *As adjunct with digitalis and diuretics to treat heart failure*

## **ORAL SUSPENSION, TABLETS**

**Adults.** *Initial:* 5 mg daily. *Maintenance:* 5 to 20 mg daily. *Maximum:* 80 mg daily.

***DOSAGE ADJUSTMENT*** For patients with hyponatremia or creatinine clearance of 30 ml/min or less, initial dosage reduced to 2.5 mg daily with maximum dosage not to exceed 40 mg once daily.

- *To improve survival in hemodynamically stable patient within 24 hours of an acute MI*

## **ORAL SUSPENSION, TABLETS**

**Adults.** 5 mg within 24 hr after onset of symptoms, followed by 5 mg after 24 hr and 10 mg after 48 hr. *Maintenance:* 10 mg daily for 6 wk.

***DOSAGE ADJUSTMENT*** For patients with baseline systolic blood pressure of 120 mm Hg or less, initial dosage decreased to 2.5 mg daily for first 3 days after MI. If systolic blood pressure falls to 100 mm Hg or less during therapy, maintenance dosage decreased to 2.5 or 5 mg as tolerated; if systolic blood pressure is 90 mm Hg or less for more than 1 hr, drug discontinued. For adult patients, regardless of indication, with impaired renal function (creatinine clearance of 10 to 30 ml/min), initial dosage reduced by half; for patients on hemodialysis or with a creatinine clearance of less than 10 ml/min, initial dose reduced to 2.5 mg once daily.

Route	Onset	Peak	Duration
P.O.	1 hr	6-8 hr	24 hr

## Mechanism of Action

May reduce blood pressure by inhibiting conversion of angiotensin I to angiotensin II. Angiotensin II is a potent vasoconstrictor that also stimulates adrenal cortex to secrete aldosterone. Lisinopril may also inhibit renal and vascular production of angiotensin II. Decreased release of aldosterone reduces sodium and water reabsorption and increases their excretion, thereby reducing blood pressure.

## Contraindications

Concurrent aliskiren use in patients with diabetes; hereditary or idiopathic angioedema or history of angioedema related to previous treatment with an ACE inhibitor; hypersensitivity to lisinopril, other ACE inhibitors, or their components; use of a neprilysin inhibitor such as sacubitril within 36 hours

## Interactions

### DRUGS

*aliskiren (in presence of diabetes or renal impairment), other ACE inhibitors, angiotension receptor blockers:*

Increased risk of hypotension, hyperkalemia, and renal impairment

*diuretics, other antihypertensives:* Increased hypotensive effect

*gold (injectible form such as sodium aurothiomalate):*

Possibly nitritoid reaction (facial flushing, hypotension, nausea, vomiting)

*insulin, oral antidiabetics:* Increased risk of hypoglycemia

*lithium:* Increased blood lithium level and risk of lithium toxicity

*mTOR inhibitors such as everolimus, sirolimus,*

*temsirolimus; neprilysin inhibitors such as sacubitril:*

Increased risk for angioedema

*NSAIDs:* Possibly reduced antihypertensive effect; possibly reduced renal function in patients with preexisting renal dysfunction, the elderly and patients who are volume-depleted

*potassium-sparing diuretics:* Increased risk of hyperkalemia

*thiazide diuretics:* Increased risk of hypokalemia

## **FOODS**

*high-potassium diet, potassium-containing salt substitutes:*

Increased risk of hyperkalemia

## **Adverse Reactions**

**CNS:** Ataxia, confusion, **CVA**, depression, dizziness, fatigue, hallucinations, headache, insomnia, irritability, memory impairment, mood alterations, nervousness, paresthesia, peripheral neuropathy, somnolence, syncope, transient ischemic attack, tremor, vertigo

**CV:** **Arrhythmias**, chest pain, fluid overload, **hypotension**, **MI**, orthostatic hypotension, palpitations, peripheral edema, vasculitis

**ENDO:** Hyperglycemia, syndrome of inappropriate ADH secretion

**EENT:** Blurred vision, diplopia, dry mouth, olfactory or taste disturbance, photophobia, tinnitus, visual loss

**GI:** Abdominal pain, anorexia, cholestatic jaundice, constipation, diarrhea, elevated liver enzymes, flatulence,

**fulminant hepatic necrosis**, gastritis, **hepatitis**, indigestion, nausea, **pancreatitis**, vomiting

**GU: Acute renal failure**, decreased libido, impotence, pyelonephritis

**HEME: Agranulocytosis**, anemia, **hemolytic anemia**, **neutropenia**, **thrombocytopenia**

**MS: Arthralgia**, arthritis, bone or joint pain, muscle spasms, myalgia

**RESP: Bronchospasm**, cough, dyspnea, paroxysmal nocturnal dyspnea, **pulmonary embolism and infarction**, upper respiratory tract infection

**SKIN: Alopecia**, cutaneous pseudolymphoma, diaphoresis, erythema, flushing, herpes zoster, infections, pemphigus, photosensitivity, pruritus, psoriasis, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other: Anaphylaxis**, **angioedema**, dehydration, gout, **hyperkalemia**, **hyponatremia**, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm. Drug given during the second or third trimester reduces fetal renal function and increases fetal and neonatal morbidity and death. Resulting oligohydramnios can cause fetal lung hypoplasia and skeletal malformations.
- Drug should be discontinued as soon as pregnancy is known.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Be aware that lisinopril should not be given to a patient who is hemodynamically unstable after an acute MI.
- Use lisinopril cautiously in patients with fluid volume deficit, heart failure, impaired renal function, or sodium depletion.
- Also use cautiously in patients with severe aortic stenosis or hypertrophic cardiomyopathy because symptomatic hypotension may occur.
- Prepare pediatric suspension by adding 10 ml purified water to a polyethylene terephthalate (PET) bottle containing 10 20-mg tablets and shake for at least 1 minute. Add 30 ml of Bicitra diluent and 160 ml of Ora-Sweet SF to concentrate in PET bottle and shake gently for several seconds. Refrigerate up to 4 weeks. Shake suspension before each use.
- Monitor blood pressure often, especially during the first 2 weeks of therapy and whenever the dose of lisinopril and/or prescribed diuretic is increased. If excessive hypotension develops, expect to withhold drug for several days.

**WARNING** Keep in mind if angioedema, affects face, glottis, larynx, limbs, lips, mucous membranes, or tongue, notify prescriber immediately and expect to stop lisinopril and start appropriate therapy at once. If airway obstruction threatens, promptly give 0.3 to 0.5 ml of epinephrine 1:1000 solution subcutaneously, as prescribed.

- Monitor patient for anaphylaxis, especially patient being dialyzed with high-flux membranes. If anaphylaxis occurs, stop dialysis immediately and treat aggressively (antihistamines are ineffective in this situation), as ordered. Anaphylaxis has also occurred with some patients undergoing low-density lipoprotein apheresis with dextran sulfate absorption.
- Notify prescriber if patient has persistent, nonproductive cough, a common adverse effect of ACE inhibitors such as lisinopril.
- Monitor for dehydration, which can lead to hypotension especially if patient experiences diarrhea or vomiting.
- Monitor patient for hepatic dysfunction because lisinopril, an ACE inhibitor, may rarely cause a syndrome that starts with cholestatic

jaundice or hepatitis and progresses to fulminant hepatic necrosis. If patient develops jaundice or a marked elevation in liver enzymes, withhold drug and notify prescriber.

- Monitor patient's serum creatinine, as ordered because changes in renal function can occur with lisinopril use. If renal function decreases, alert prescriber and expect drug to be withheld or discontinued.
- If patient takes insulin or an oral antidiabetic, monitor blood glucose level closely because risk of hypoglycemia increases, especially during first month of therapy.
- Monitor patient's serum potassium level, as ordered because drugs that inhibit the renin-angiotensin system such as lisinopril can cause hyperkalemia. Patients at increased risk for developing hyperkalemia include patients with diabetes or renal insufficiency or who are also taking potassium-sparing diuretics, potassium containing salt substitutes, or potassium supplements.

## PATIENT TEACHING

- Explain that lisinopril helps to control, but doesn't cure, hypertension and that patient may need lifelong therapy.

**WARNING** Warn patient to seek immediate emergency treatment if she experiences difficulty breathing or swallowing or notices swelling of her eyes, extremities, face, lips, or tongue.

- Advise patient to take lisinopril at the same time every day.
- Emphasize need to take drug as ordered, even if patient feels well; caution her not to stop drug without consulting prescriber.
- Instruct patient to report dizziness, especially during first few days of therapy.
- Caution her to avoid hazardous activities such as driving until dizziness or other nervous system symptoms abates.
- Inform patient that persistent, nonproductive cough may develop during lisinopril therapy. Urge her to notify prescriber immediately if cough becomes difficult to tolerate.
- Advise patient to drink adequate fluids and avoid excessive sweating, which can lead to dehydration and hypotension. Make sure she

understands that diarrhea excessive perspiration, and vomiting can also cause hypotension.

- Caution patient not to use salt substitutes that contain potassium.
- Instruct patient to report signs of infection, such as fever and sore throat, which may indicate neutropenia.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- If patient has diabetes and takes insulin or an oral antidiabetic, urge her to monitor her blood glucose level closely and watch for symptoms of hypoglycemia.
- Caution female patient to notify prescriber immediately if she is or could be pregnant because lisinopril must be discontinued. Also inform her that breastfeeding is not recommended during lisinopril therapy because severe adverse reactions may develop in the infant.
- Advise patient to inform all prescribers of lisinopril therapy.

## **lithium carbonate**

**Carbolith (CAN), Duralith (CAN),  
Lithane (CAN), Lithobid**

## **lithium citrate**

### **Class and Category**

*Pharmacologic class:* Alkali metal

*Therapeutic class:* Antimanic

### **Indications and Dosages**

- *To treat acute mania episodes of bipolar disorder; to maintain patients with bipolar disorder*

## **CAPSULES, TABLETS**

**Adults and children age 7 and over weighing 30 kg (66 lb) or more.** *Initial:* 300 mg three times daily, increased every 3 days by 300 mg, as needed. *Acute goal:* 600 mg two to three times daily. *Maintenance:* 300 to 600 mg two to three times daily.

**Children ages 7 and over weighing 20 (44 lb) to 30 kg (66 lb).** *Initial:* 300 mg twice daily, increased 300 mg weekly. *Acute goal:* 600 mg to 1,500 mg in divided doses daily. *Maintenance:* 600 mg to 1,200 mg in divided doses daily.

## **E.R. TABLETS**

**Adults and children age 12 and over.** *Initial:* 900 mg twice daily. *Maintenance:* 600 mg twice daily.

## **ORAL SOLUTION**

**Adults and children age 7 and over weighing 30 kg (66 lb) or more.** *Initial:* 8 mEq (5 ml) three times daily, increased by 8 mEq (5 ml) every 3 days, as needed. *Acute goal:* 16 mEq (10 ml) two to three times daily. *Maintenance:* 8 to 16 mEq (5 to 10 ml) two to three times daily.

**Children age 7 and over weighing 20 kg (44 lb) to 30 kg (66 lb).** *Initial:* 8 mEq (5 ml) twice daily, increased by 8 mEq (5 ml) weekly, as needed. *Acute goal:* 16 to 40 mEq (10 to 25 ml) in divided doses daily. *Maintenance:* 16 to 32 mEq (10 to 20 ml) in divided doses daily.

## **SYRUP (LITHIUM CITRATE)**

**Adults and children age 12 and over.** *Initial:* 16 mEq (10 ml) three times daily. *Maintenance:* 8 mEq (5 ml) three or four times daily.

***DOSAGE ADJUSTMENT*** For elderly patient and patient at risk for lithium toxicity, such as in the presence of severe debilitation or dehydration, or significant cardiovascular or renal disease or who is taking drugs that may affect kidney function such as angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, diuretics, or NSAIDs, initial dosage may have to be reduced and titration done slowly.

Route	Onset	Peak	Duration
P.O.	1-3 wk	Unknown	Unknown

## Mechanism of Action

May increase presynaptic degradation of the catecholamine neurotransmitters dopamine, norepinephrine, and serotonin; inhibit their release at neuronal synapses; and decrease postsynaptic receptor sensitivity. These actions may correct overactive catecholamine systems in patients with mania.

## Contraindications

Hypersensitivity to lithium or its components

## Interactions

### DRUGS

*ACE inhibitors, angiotensin receptor blockers, diuretics, metronidazole, NSAIDs:* Possibly increased blood lithium level and increased risk of toxicity

*acetazolamide, sodium bicarbonate, urea, xanthines:*  
Decreased blood lithium level  
*buspirone, fentanyl, MAO inhibitors, norepinephrine  
reuptake inhibitors, selective serotonin reuptake inhibitors,  
St. John's wort, tramadol, tricyclic antidepressants,  
triptans, tryptophan:* Increased risk of serotonin syndrome  
*calcium channel blockers:* Increased risk of neurotoxicity  
from lithium  
*calcium iodide, iodinated glycerol, potassium iodide:*  
Possibly increased hypothyroid effects of both drugs  
*carbamazepine, methyldopa, phenytoin:* Possibly increased  
risk of adverse reactions with these drugs  
*haloperidol and other antipsychotics:* Increased risk of  
neurotoxicity ranging from extrapyramidal symptoms to  
neuroleptic malignant syndrome  
*neuromuscular blockers:* Risk of prolonged effects

## Adverse Reactions

**CNS:** Ataxia, coma, confusion, depression, disorientation,  
dizziness, drowsiness, fatigue, headache, lethargy,  
**seizures, serotonin syndrome**, syncope, tremor (in  
hands), vertigo

**CV:** **Arrhythmias, bradycardia, ECG changes**, edema,  
**hypotension**, palpitations, **peripheral circulatory  
collapse**, tachycardia, unmasking of **Brugada syndrome**

**EENT:** Blurred vision, dental caries, dry mouth,  
exophthalmos

**ENDO:** Diabetes insipidus, euthyroid goiter,  
hypothyroidism, **myxedema**, polydipsia

**GI:** Abdominal distention and pain, anorexia, diarrhea,  
nausea, vomiting

**GU:** **Nephrotic syndrome**, polyuria, stress incontinence,  
urinary frequency

**HEME:** Leukocytosis

**MS:** Muscle twitching and weakness

**RESP:** Dyspnea

**SKIN:** Acne; alopecia; dermatitis; dry, thin hair; pruritus; rash

**Other:** Cold sensitivity, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm in first trimester, such as cardiovascular and other anomalies, and especially Ebstein's anomaly.
- Drug may cause fetal harm late in pregnancy with increased risk of neonatal lithium toxicity at birth.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Administer lithium after meals to slow absorption from GI tract and reduce adverse reactions. Dilute syrup with juice or other flavored drink before giving.
- Note that 5 ml of lithium citrate equals 8 mEq of lithium ion or 300 mg of lithium carbonate.
- Expect to monitor blood lithium level two or three times weekly during first month, and then weekly to monthly during maintenance therapy and when starting or stopping NSAID therapy. In uncomplicated cases, plan to monitor lithium level every 2 to 3 months.

- Be aware that lithium has a narrow therapeutic range. Even a slightly high blood level is dangerous, and some patients show signs of toxicity at normal levels. Be aware that risk of toxicity is increased in patients with electrolyte changes (especially potassium and sodium), recent onset of a concurrent febrile illness, severe debilitation or dehydration, or significant cardiovascular or renal disease, and in patients taking other drugs that affect kidney function, such as angiotensin-converting enzyme inhibitors, angiotensin receptor blockers, diuretics, and NSAIDs. Lithium toxicity signs and symptoms affect many areas of the body and can range from mild to severe and life-threatening symptoms. No antidote for lithium toxicity is available.
- Expect prescriber to decrease dosage after acute manic episode is controlled.

**WARNING** Be aware that lithium affects extracellular and intracellular potassium ion shift, which can cause ECG changes, such as flattened or inverted T waves; it also can increase the risk of cardiac arrest.

- Monitor ECGs, renal and thyroid function test results, and serum electrolyte levels, as appropriate, during lithium treatment. Know that nephrotic syndrome has occurred with lithium use but has resulted in remission after lithium was discontinued.

**WARNING** Be aware that lithium can cause reversible leukocytosis, which usually peaks within 7 to 10 days of starting therapy; WBC count typically returns to baseline within 10 days after therapy stops.

- Weigh patient daily to detect sudden weight changes.
- Monitor blood glucose level often in diabetic patient because lithium alters glucose tolerance.
- Palpate thyroid gland to detect enlargement because drug may cause goiter.
- Ensure that patient's fluid and sodium intake is adequate during treatment.
- Monitor patient closely for unexplained palpitations or syncope after starting lithium therapy as these symptoms may be caused by the unmasking of Brugada syndrome by lithium. Know that Brugada syndrome

is a disorder in which electrocardiographic abnormalities occur and can result in sudden death. Patients at risk include those with a family history of Brugada syndrome or a family history of sudden death before the age of 45 years. Notify prescriber if palpitations or syncope occur and expect to discontinue lithium therapy.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of lithium. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. If symptoms occur, notify prescriber immediately, expect drug to be discontinued, and provide supportive care.

## **PATIENT TEACHING**

- Advise patient to take lithium with or after meals to minimize adverse reactions.
- Instruct patient to swallow E.R. form whole.
- Direct patient to mix syrup form with juice or other flavored drink before taking.
- Inform patient that frequent urination, nausea, and thirst may occur during the first few days of treatment.
- Caution patient not to stop taking lithium or adjust dosage without first consulting prescriber.
- Instruct patient to report signs of toxicity, such as diarrhea, drowsiness, muscle weakness, tremor, uncoordinated body movements, and vomiting.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to maintain normal fluid and sodium intake.
- Emphasize importance of complying with scheduled checkups and laboratory tests.
- Instruct patient to seek immediate emergency care if he experiences abnormal heart beats, fainting, lightheadedness, or shortness of breath.

# lixisenatide

**Adlyxin**

## Class and Category

*Pharmacologic class:* Glucagon-like peptide receptor agonist

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *Adjunct to diet and exercise to improve glycemic control in patients with type 2 diabetes mellitus*

## SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 10 mcg within 1 hr before first meal of day once daily for 14 days. Increased to 20 mcg once daily on day 15 and thereafter. **Maintenance:** 20 mcg once daily.

## Mechanism of Action

As a glucagon-like peptide receptor agonist, lixisenatide decreases glucagon secretion, increases glucose-dependent insulin release, and slows gastric emptying. All of these actions work together to reduce blood glucose levels.

## Contraindications

Hypersensitivity to lixisenatide or its components

# Interactions

## DRUGS

*basal insulin, sulfonylureas:* Increased risk of hypoglycemia  
*orally administered drugs:* Possibly delayed absorption of orally administered drugs resulting in decreased effectiveness

## Adverse Reactions

**CNS:** Dizziness, headache

**EENT:** Laryngeal edema

**GI:** Abdominal distention or pain, acute pancreatitis, constipation, diarrhea, dyspepsia, nausea, vomiting

**GU:** Acute kidney injury, worsening of chronic renal failure

**RESP:** Bronchospasms

**SKIN:** Urticaria

**Other:** Anaphylaxis; angioedema; injection-site reactions such as erythema, pain, and pruritus; lixisenatide-induced antibodies

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm based on animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Administer lixisenatide subcutaneously 1 hour before the patient's first meal of the day into the patient's abdomen, thighs, or upper arm. Rotate sites.
- Protect the pen device containing the drug from light by keeping it in its original packaging. Write date that pen was first used on packaging and discard 14 days later.

**WARNING** Monitor patient closely for hypersensitivity reactions that could become serious, especially if patient has a history of hypersensitivity to other drugs in the same class.

- Monitor patient for signs and symptoms of pancreatitis including persistent severe abdominal pain, sometimes radiating to the back, that may or may not be accompanied with vomiting. Know that risk increases in patients who have a history of alcohol abuse or cholelithiasis. If pancreatitis is suspected, notify prescriber, discontinue drug, and provide supportive care, as ordered.
- Monitor patient for hypoglycemia, especially in patients who also take basal insulin and/or a sulfonylurea. Be prepared to treat hypoglycemia should it occur. Notify prescriber of persistent or severe hypoglycemic episodes as a dosage reduction in the insulin or sulfonylurea may be needed.
- Monitor patient's renal function before lixisenatide is initiated and during therapy, as ordered. Know that acute kidney injury can occur quickly even in patients who have no history of kidney disease. Patients are at increased risk when they experience dehydration, diarrhea, nausea, or vomiting. Notify prescriber immediately if patient's fluid balance is compromised.

## PATIENT TEACHING

- Instruct patient or caregiver on how to administer drug subcutaneously, if self-administration is prescribed. Provide instructions on how to use the

pen device correctly. Tell patient how to dispose of pen properly and to keep out of reach of children and pets.

- Tell patient to inspect solution in pen before administering. It should appear clear and colorless.
- Instruct patient to administer lixisenatide 1 hour before the first meal of the day by injecting into her abdomen, thigh, or upper arm. Stress importance of rotating sites. Tell her it is best to administer the drug before the same meal each day.
- Inform patient that if she forgets a dose, she should administer the drug within 1 hour prior to the next meal but never double the dose to make up for a missed dose.
- Tell patient to protect the pen from light by keeping it in the original packaging. She should also write down the date the pen was first used, as pen must be discarded 14 days later.
- Inform women who are taking oral contraceptives that lixisenatide may interfere with absorption and effectiveness of oral contraceptive. To avoid this, tell patient to take oral contraceptive 1 hour before or 11 hours after administering lixisenatide each day.
- Tell all patients taking oral medication to take them at least 1 hour before administering lixisenatide; if a prescribed drug requires food intake, take it with a meal or snack that does not coincide with lixisenatide administration.
- Warn patient never to share the pen used to inject lixisenatide even if the needle is changed, because of an increased risk for transmission of blood-borne diseases.
- Remind patient that lixisenatide does not take the place of dietary measures and exercise also used to control blood sugar.
- Advise patient to maintain adequate hydration. Emphasize importance of alerting prescriber immediately if she does become dehydrated or develops diarrhea, nausea, or vomiting.

**WARNING** Instruct patient to seek immediate medical attention if she develops an allergic reaction to drug.

- Review signs and symptoms of pancreatitis with patient and urge her to stop taking drug and notify the prescriber, if present.
- Encourage patient to be on the alert for hypoglycemia, especially if she is taking basal insulin or sulfonylurea. Review the signs and symptoms and how to treat it. If episodes occur frequently or become severe, tell her to

notify prescriber, as a dosage reduction may be needed for her basal insulin or sulfonylurea.

## lofexidine

**Lucemyra**

### Class and Category

*Pharmacologic class:* Central  $\alpha_2$ -agonist

*Therapeutic class:* Opioid withdrawal

### Indications and Dosages

- *To mitigate opioid withdrawal symptoms in order to facilitate abrupt opioid discontinuation*

#### **TABLETS**

**Adults.** 3 tablets (0.18 mg each) four times daily with 5 to 6 hr between each dose and continued during the period of peak withdrawal (usually first 5 to 7 days following last use of an opioid, although peak withdrawal may last up to 14 days). Then, dosage gradually reduced over 2 to 4 days by reducing 1 tablet per dose every 1 to 2 days. *Maximum:* 4 tablets (total 0.72 mg) for a single dose, 16 tablets (total 2.88 mg) daily.

***DOSAGE ADJUSTMENT*** For patients experiencing drug-related adverse reactions, dosage reduced, held, or drug discontinued depending on severity of reactions. Dosage may be reduced as opioid withdrawal symptoms wane. For patient with moderate hepatic or renal impairment, dosage

reduced to 2 tablets four times daily; for patient with severe hepatic or renal impairment, dosage reduced to 1 tablet four times daily.

## **Mechanism of Action**

Binds to receptors on adrenergic neurons to reduce the release of norepinephrine and decrease sympathetic tone, thereby reducing opioid withdrawal symptoms.

## **Contraindications**

Hypersensitivity to lofexidine or its components

## **Interactions**

### **DRUGS**

*CNS depressants such as barbiturates and other sedating drugs:* Possibly potentiates effects of CNS depressants

*CYP2D6 inhibitors such as paroxetine:* Increased absorption of lofexidine, increasing risk for bradycardia and orthostatic hypotension

*methadone:* Increased risk of QT prolongation leading to life-threatening arrhythmias

*naltrexone (oral):* Possibly reduced effectiveness of oral naltrexone if administered within 2 hours of lofexidine

### **ACTIVITIES**

*alcohol use:* Possibly potentiates CNS depressant effect of alcohol

## **Adverse Reactions**

**CNS:** Dizziness, insomnia, sedation, somnolence, syncope  
**CV:** Bradycardia, hypotension, orthostatic hypotension, **QT prolongation, torsades de pointes**  
**EENT:** Dry mouth, tinnitus  
**Other:** Discontinuation effects (anxiety, chills, diarrhea, elevation of blood pressure, extremity pain, hyperhidrosis, insomnia)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that lofexidine should not be used in patients with cerebrovascular disease, congenital long QT syndrome, marked bradycardia, recent myocardial infarction, or severe coronary insufficiency.
- Monitor vital signs before administering each dose of lofexidine, because drug may cause a decrease in blood pressure or pulse and cause syncope.

**WARNING** Know that lofexidine prolongs the QT interval. Expect to monitor patient's ECG if he has a history of bradyarrhythmias, congestive heart failure, or hepatic or renal impairment; ECG should also be monitored in

patients with electrolyte abnormalities such as hypokalemia or hypomagnesemia. Know that electrolyte imbalances should be corrected before lofexidine therapy begins.

- Be aware that lofexidine therapy should not be stopped abruptly but gradually withdrawn to reduce the risk of discontinuation symptoms such as a sudden rise in blood pressure along with anxiety, chills, diarrhea, excessive sweating, extremity pain, and insomnia. If patient stops drug use abruptly, symptoms can be managed by administering the previous lofexidine dose and then subsequently gradually tapering drug dosage downward.

## **PATIENT TEACHING**

- Instruct patient to take lofexidine exactly as prescribed. Warn patient that stopping drug abruptly can result in a sudden rise in blood pressure along with anxiety, chills, diarrhea, excessive sweating, extremity pain, and insomnia. Caution him that drug must be gradually withdrawn.
- Tell patient that lofexidine therapy will help with opioid withdrawal symptoms but will not completely prevent them.
- Inform patient that lofexidine may cause a sudden drop in blood pressure or pulse. Instruct patient to rise slowly from a lying or sitting position and to maintain adequate hydration, as well as avoid becoming overheated, to help minimize these effects. Tell patient that if he experiences low blood pressure or decreased pulse rate to withhold the drug and notify the prescriber for guidance on how to adjust his dose.
- Tell patient to inform all prescribers of lofexidine therapy and not to take any over-the-counter preparations, including herbal products, without consulting prescriber, as the combination may cause an excessive drop in blood pressure or pulse rate.
- Instruct patient to avoid performing hazardous activities such as driving until the drug's effects on his nervous system are known.

**WARNING** Alert patient that lofexidine is not a treatment for opioid use. Tell patient that upon complete opioid discontinuation, he is more likely to have a reduced tolerance to opioids and is at increased risk for a fatal overdose should he resume opioid use. Make sure both

patient and caregivers are aware of the increased risk of overdose.

- Warn patient to avoid taking any CNS depressant drugs such as barbiturates, benzodiazepines, or other sedating drugs while taking lofexidine, because severe respiratory depression and sedation may occur. Also warn patient not to drink alcohol while taking drug, for the same reason.

## lomitapide mesylate

### Juxtapid

## Class and Category

*Pharmacologic class:* Microsomal triglyceride transfer protein (MTP) inhibitor

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *To control lipid levels as adjunct to diet and other lipid-lowering treatments in homozygous familial hypercholesterolemia*

### CAPSULES

**Adults.** *Initial:* 5 mg once daily with full glass of water 2 hr after evening meal with dosage increased to 10 mg once daily after 2 wk, as needed. Dosage further increased in 4 wk increments to 20 mg once daily, then to 40 mg once daily to 60 mg once daily, as needed. *Maximum:* 60 mg once daily.

**DOSAGE ADJUSTMENT** For patients with mild hepatic impairment or with end-stage renal impairment requiring dialysis, dosage not to exceed 40 mg once daily. For patients receiving weak CYP3A4 inhibitors such as alprazolam, amiodarone, amlodipine, atorvastatin, bicalutamide, cilostazol, cimetidine, cyclosporine, fluoxetine, fluvoxamine, ginkgo, goldenseal, isoniazid, lapatinib, nilotinib, pazopanib, ranolazine, ticagrelor, or zileuton, initial dosage of 10 mg or more reduced by half and maximum dosage not to exceed 30 mg once daily. However, for patient taking oral contraceptives which are also weak CYP3A4 inhibitors, maximum daily dosage reduced to 40 mg daily. For patients who develop elevated transaminases three times or greater but less than five times upper normal limits during therapy, daily dosage reduced with degree of reduction individualized.

## **Mechanism of Action**

Binds and inhibits microsomal triglyceride transfer protein, located in the lumen of the endoplasmic reticulum of cells which in turn prevents the assembly of apo B-containing lipoproteins in enterocytes and hepatocytes. This then prevents the synthesis of chylomicrons and very low-density lipoproteins (VLDL). Lower VLDL levels leads to reduced levels of plasma low-density lipoprotein-cholesterol.

## **Contraindications**

Active liver disease, concurrent therapy with moderate or strong CYP3A4 inhibitors, hypersensitivity to lomitapide or its components, moderate or severe hepatic impairment, pregnancy, unexplained persistent elevations of serum transaminases

# Interactions

## DRUGS

*bile acid sequestrants*: Possibly decreased absorption of lomitapide

*CYP3A inhibitors*: Increased lomitapide exposure with possible increased risk of adverse reactions

*lovastatin, simvastatin*: Increased risk of myopathy, including rhabdomyolysis

*P-glycoprotein substrates such as aliskiren, colchicine, dabigatran etexilate, digoxin, everolimus, fexofenadine, imatinib, lapatinib, maraviroc, nilotinib, posaconazole, ranolazine, saxagliptin, sirolimus, sitagliptin, talinolol, tolvaptan, topotecan*: Increased absorption of these drugs resulting in higher drug levels

*warfarin*: Increased plasma warfarin levels with possible increased risk of bleeding events

## FOODS

*grapefruit juice*: Increased lomitapide exposure and adverse reactions

## ACTIVITIES

*alcohol use*: Possibly increased risk of hepatic steatosis

# Adverse Reactions

**CNS**: Dizziness, fatigue, fever, headache

**CV**: Chest pain, palpitations

**EENT**: Nasal congestion, nasopharyngitis, pharyngolaryngeal pain

**GI**: Abdominal distention or pain, constipation, defecation urgency, diarrhea (may become severe), dyspepsia,

elevated liver enzymes, flatulence, gastroenteritis, gastroesophageal reflux disease, hepatic steatosis, **hepatotoxicity**, nausea, rectal tenesmus, transaminase elevations, vomiting

**MS:** Back pain, myalgia

**SKIN:** Alopecia

**Other:** Fat-soluble vitamin deficiency, flu-like symptoms, serum fatty acid deficiency, weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy Exposure Registry: 1-877-902-4099.
- Drug may cause fetal harm.
- Drug is contraindicated in pregnancy.
- Women of childbearing age should have a negative pregnancy test before starting drug.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

### REPRODUCTION

- Advise women of childbearing age pregnancy should be avoided during drug therapy.
- Women of childbearing age must use effective contraception during drug therapy.

## Nursing Considerations

- Be aware that lomitapide should not be given to patients with rare, hereditary problems of galactose intolerance, glucose-galactose malabsorption, or Lapp lactase deficiency because drug may cause diarrhea and malabsorption in these patients.
- Know that because lomitapide increases risk of hepatotoxicity, the drug can only be administered through the Juxtapid REMS program.
- Determine patient has had ALT, AST, alkaline phosphatase and total bilirubin measured, has had a negative pregnancy test if patient is female, and has initiated a low-fat diet supplying less than 20% of energy from fat prior to initiating lomitapide therapy.
- Be aware that ALT and AST levels should be measured prior to potential dosage increase or monthly, whichever comes first, for first year of therapy and then before each actual dosage increase and every 3 months thereafter. If transaminase values are equal to or greater than three times upper limit normal but less than five times upper limit normal, expect to confirm elevation with a repeat measurement within 1 week. If confirmed, expect dosage to be decreased and additional liver-related tests done, such as measurement of alkaline phosphatase, total bilirubin, and patient's INR. Repeat tests weekly, as ordered, and expect to withhold drug if there are signs of abnormal liver function such as an elevation in patient's bilirubin or an increase in patient's INR. If transaminase levels are above five times upper limit normal, or if transaminase levels do not fall below three times upper limit normal within about 4 weeks, expect drug to be withheld or discontinued. Know that if drug therapy is resumed, dosage should be reduced and more frequent liver-related tests ordered.
- Monitor patient closely for signs and symptoms of liver impairment, such as presence of abdominal pain, fever, flu-like symptoms, jaundice, or lethargy; a bilirubin result that is equal to or greater than two times upper limit normal, or active liver disease is suspected because risk of hepatotoxicity increases with lomitapide therapy.
- Monitor patient for fat-soluble vitamin and fatty acids deficiencies, especially patients with chronic bowel or pancreatic diseases that predispose to malabsorption, because lomitapide reduces the absorption of fat-soluble vitamins.
- Monitor patient for adverse reactions, especially gastrointestinal reactions, which are the most common reactions associated with lomitapide therapy. Give drug with a full glass of water 2 hours after evening meals. Ensure patient is adhering to a low-fat diet that supplies less than 20% of energy needs from fat to reduce the risk of adverse gastrointestinal reactions.

- Know that lomitapide may cause severe diarrhea in some patients, requiring hospitalization because of diarrhea-induced volume depletion. Monitor patients closely, especially the elderly and those who are taking drugs that can lead to hypotension or volume depletion.

## PATIENT TEACHING

- Advise patient to take lomitapide with a full glass of water 2 hours after the evening meal because taking drug with food may increase the risk of gastrointestinal adverse reactions.
- Caution patient to swallow capsule whole and not to chew, crush, dissolve, or open capsule.
- Instruct patient to take daily supplements of 400 international units of vitamin E and at least 210 mg alpha-linolenic acid, 110 mg eicosapentaenoic acid, and 80 mg of docosahexaenoic acid to prevent deficiencies.
- Remind patient of importance of adhering to the low-fat diet prescribed as lomitapide therapy is not a replacement for dietary control of fat in her diet.
- Tell patient to inform all prescribers about lomitapide therapy because of potential drug interactions.
- Review signs and symptoms of liver impairment, and emphasize importance of reporting such to prescriber. Inform patient of need for blood tests to monitor her liver function and importance of compliance with test schedule.
- Instruct patient to stop taking drug and notify prescriber if severe diarrhea occurs or if he experiences symptoms such as decreased urine output, lightheadedness, or unexplainable tiredness that accompanies diarrhea.

**WARNING** Instruct patient not to consume more than one alcoholic beverage daily.

**WARNING** Caution women of childbearing age to notify prescriber immediately if pregnancy occurs or is suspected because drug will have to be discontinued. Also, encourage them to enroll in the pregnancy exposure registry that monitors pregnancy outcomes in women exposed to the drug during pregnancy. Also

inform these women that breastfeeding is not recommended during drug therapy.

## lorazepam

**Ativan, Lorazepam Intensol, Nu-Loraz (CAN)**

### Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anxiolytic

*Controlled substance schedule:* IV

### Indications and Dosages

➤ *To treat anxiety*

#### ORAL CONCENTRATE, TABLETS

**Adults.** *Initial:* 2 to 3 mg twice daily or three times daily, increased as needed. *Usual:* 2 to 6 mg daily in divided doses, with the largest dose taken before bedtime.

*Maximum:* 10 mg daily.

***DOSAGE ADJUSTMENT*** For elderly or debilitated patients, initial dosage may be reduced to 1 to 2 mg daily in divided doses.

➤ *To treat insomnia caused by anxiety*

#### ORAL CONCENTRATE, TABLETS

**Adults.** 2 to 4 mg at bedtime.

**DOSAGE ADJUSTMENT** Dosage possibly reduced for elderly or debilitated patients.

➤ *To provide preoperative sedation*

## I.V. INJECTION

**Adults.** 0.044 mg/kg or 2 mg, whichever is less, given at 2 mg/min 2 hr before procedure. Higher dosage may be required for some patients but not to exceed maximum dose. *Maximum:* 0.05 mg/kg or total of 4 mg.

## I.M. INJECTION

**Adults.** 0.05 mg/kg up to maximum dosage 2 hr before procedure. *Maximum:* 4 mg.

➤ *To treat status epilepticus*

## I.V. INJECTION, I.M. INJECTION (ONLY IF I.V. INJECTION CANNOT BE USED)

**Adults.** *Initial:* 4 mg at a rate of 2 mg/min. Repeated in 10 to 15 min if seizures don't subside. *Maximum:* 8 mg/24 hr.

**DOSAGE ADJUSTMENT** For patients receiving drug I.M. or I.V. and also taking probenecid or valproate, dosage reduced by 50%. Dosage may need to be increased in female patients who are concomitantly taking oral contraceptives.

Route	Onset	Peak	Duration
I.V.	5 min	Unknown	12-24 hr
I.M.	15-30 min	Unknown	12-24 hr

## Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding

to specific benzodiazepine receptors in cortical and limbic areas of CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. Limbic system contains a highly dense area of benzodiazepine receptors, which may explain drug's antianxiety effects. Also, lorazepam hyperpolarizes neuronal cells, thereby interfering with their ability to generate seizures.

## Incompatibilities

Don't mix I.V. lorazepam in same syringe as buprenorphine.

## Contraindications

*For all forms of lorazepam:* Acute angle-closure glaucoma; hypersensitivity to lorazepam, other benzodiazepines, or their components; *For parenteral form:* intra-arterial delivery premature infants, severe respiratory insufficiency (except in patients requiring anxiety relief and/or diminished recall of events while being mechanically ventilated), sleep apnea syndrome

## Interactions

### DRUGS

*aminophylline, theophylline:* Possibly reduced sedative effects of lorazepam

*clozapine:* Increased risk of ataxia, delirium, excessive salivation, hypotension, marked sedation, and respiratory arrest

*CNS depressants:* Additive CNS depression, potentially fatal respiratory depression

*fentanyl:* Possibly decreased therapeutic effects of fentanyl

*probenecid, valproate*: Possibly increased therapeutic and adverse effects of lorazepam

*other benzodiazepines, sedating antihistamines, opioids, tricyclic antidepressants*: Increased risk of profound respiratory depression, sedation, and somnolence

## ACTIVITIES

*alcohol use*: Increased CNS depression and severe respiratory depression

## Adverse Reactions

**CNS**: Amnesia, anxiety, ataxia, **coma**, confusion, delusions, depression, dizziness, drowsiness, euphoria, extrapyramidal symptoms, fatigue, headache, hypokinesia, irritability, malaise, nervousness, **seizures**, slurred speech, **suicidal ideation**, tremor, unsteadiness, vertigo

**CV**: Chest pain, palpitations, tachycardia

**EENT**: Blurred vision, diplopia, dry mouth, increased salivation, photophobia

**ENDO**: Syndrome of inappropriate ADH

**GI**: Abdominal pain, constipation, diarrhea, elevated liver enzymes, jaundice, nausea, thirst, vomiting

**GU**: Libido changes

**HEME**: **Agranulocytosis, pancytopenia, thrombocytopenia**

**RESP**: **Apnea, respiratory depression**, worsening of obstructive pulmonary disease or sleep apnea

**SKIN**: Diaphoresis

**Other**: **Anaphylaxis**, injection-site pain (I.M.) or phlebitis (I.V.), physical and psychological dependence, withdrawal symptoms

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm such as congenital abnormalities, neurotoxicity and neonatal withdrawal symptoms.
- Drug should not be used during pregnancy except in life-threatening situations.

## LACTATION

- Drug is present in breast milk.
- Drug should not be given to breastfeeding mothers unless benefit to mother outweighs the potential risk to breastfed infant.
- Infants being breastfed should be observed for inability to suckle, irritability, and sedation.

# Nursing Considerations

- Be aware that parenteral form of lorazepam is contraindicated in premature infants because the formulation contains benzyl alcohol, increasing risk of gasping syndrome, kernicterus, and toxicity. Lorazepam should be used with extreme caution in neonates because although the amount of benzyl alcohol is well below that associated with toxicity, a total daily metabolic load of benzyl alcohol from combined sources may increase the risk of toxicity.
- Before starting lorazepam therapy in a patient with depression, make sure he already takes an antidepressant, because of the increased risk of suicide in patients with untreated depression.
- Be aware that the combination of general anesthesia and sedation drugs like lorazepam used during procedures or surgeries in pregnant women in their third trimester is not recommended because it may affect brain development in the fetus.
- Use extreme caution when giving lorazepam to elderly patients, especially those with compromised respiratory function, because drug can cause hypoventilation, respiratory depression, sedation, and unsteadiness. Also, use extreme caution when administering lorazepam to children under the

age of 3 because of the risk of neurotoxicity, especially if exposed to drug longer than 3 hours or with repeated exposure.

- Use drug cautiously in patients with a history of alcohol or drug abuse or a personality disorder because of an increased risk of physical and psychological dependence. Also use cautiously in patients with encephalopathy or severe hepatic insufficiency because drug may worsen hepatic encephalopathy.
- Be aware that benzodiazepine therapy such as lorazepam should only be used concomitantly with opioids in patients for whom other treatment options are inadequate because adverse effects could be profound and possibly result in death. If prescribed together, expect dosing and duration of the opioid to be limited. Monitor patient closely for signs and symptoms of profound decrease in consciousness, including coma, sedation, and respiratory depression. Notify prescriber immediately and provide emergency supportive care.
- For I.M. use, inject lorazepam deep into large muscle mass, such as gluteus maximus.
- For I.V. use, dilute lorazepam with equal amount of D<sub>5</sub>W, sterile water for injection, or sodium chloride for injection. Give diluted lorazepam slowly, at no more than 2 mg/min.
- Monitor patient's respirations every 5 to 15 minutes and keep emergency resuscitation equipment readily available.

**WARNING** Monitor patient's respiratory status closely because drug may cause life-threatening respiratory depression.

- Know that because stopping drug abruptly increases risk of withdrawal symptoms, dosage should be tapered gradually, especially in epileptic patients.

## **PATIENT TEACHING**

- Instruct patient to take lorazepam exactly as prescribed and not to stop without consulting prescriber because of the risk of withdrawal symptoms.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.

- Urge patient to avoid alcohol while taking lorazepam because it increases drug's CNS depressant effects and can cause severe respiratory depression which may lead to death.
- Instruct patient to report excessive drowsiness and nausea.
- Inform pregnant patient that lorazepam therapy will need to be discontinued early in third trimester to avoid possible withdrawal symptoms in newborn.
- Warn patient about potentially fatal additive effects of combining lorazepam with an opioid. Instruct him to inform all prescribers of lorazepam use, especially when pain medication may be prescribed.

## lorcaserin hydrochloride

### Belviq, Belviq XR

## Class, Category, and Schedule

*Pharmacologic class:* Serotonin 2C receptor agonist

*Therapeutic class:* Appetite suppressant

*Controlled substance schedule:* IV

## Indications and Dosages

- *Adjunct to reduced-calorie diet and increased physical activity for chronic weight management in patients with an initial body mass index of 30 kg/m<sup>2</sup> or greater (obese), or 27 kg/m<sup>2</sup> or greater (overweight) in the presence of at least one weight-related comorbid condition such as dyslipidemia, hypertension, or type 2 diabetes*

## TABLETS

**Adults.** 10 mg twice daily.

## **E.R. TABLETS**

**Adults.** 20 mg once daily.

## **Mechanism of Action**

Selectively activates 5-HT<sub>2C</sub> receptors on anorexigenic pro-opiomelanocortin neurons located in the hypothalamus to decrease food consumption and promote satiety.

## **Contraindications**

Hypersensitivity to lorcaserin or its components, pregnancy

## **Interactions**

### **DRUGS**

*bupropion, dextromethorphan, linezolid, lithium, MAOIs, selective serotonin norepinephrine reuptake inhibitors (SSNRIs), selective serotonin reuptake inhibitors (SSRIs), St. John's wort, tramadol, tricyclic antidepressants (TCAs), triptans, tryptophan:* Increased risk for serotonin syndrome  
*cytochrome P450 (2D6) substrates:* Increased exposure of these drugs

## **Adverse Reactions**

**CNS:** Anxiety, cognitive impairment, depression, dizziness, euphoria, fatigue, headache, insomnia, **neuroleptic malignant syndrome-like reaction, serotonin syndrome, suicidal ideation**

**CV:** **Bradycardia**, hypertension, peripheral edema, valvulopathy

**EENT:** Abnormal ocular sensations; blurred vision; cataracts; conjunctival infections, inflammation, or irritation; dry eyes or mouth; nasopharyngitis; ocular sensation disorders; oropharyngeal pain; sinus congestion; toothache; visual impairment

**ENDO:** Elevated prolactin level, **hypoglycemia**, worsening of diabetes mellitus

**GI:** Constipation, decreased appetite, diarrhea, gastroenteritis, nausea, vomiting

**GU:** UTI

**HEME:** Anemia; **leukopenia**, **lymphopenia**, **neutropenia**

**MS:** Back or musculoskeletal pain

**RESP:** Cough, upper respiratory infection

**SKIN:** Rash

**Other:** **Hypersensitivity reactions**, seasonal allergy

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm although it may cause lower body weight in fetus, which may persist into adulthood.
- Drug is contraindicated during pregnancy because weight loss offers no benefit to a pregnant woman.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended.

## Nursing Considerations

- Use extreme caution when administering lorcaserin with any drug that affects the serotonergic neurotransmitter system, especially when drug is initiated and during dosage changes, because of the risk of serotonin syndrome.
- Use caution when administering lorcaserin to patients with congestive heart failure or hemodynamically significant valvular heart disease because lorcaserin has been linked to regurgitant cardiac valvular disease, primarily affecting the aortic and/or mitral valves. Monitor patient closely for congestive heart failure, dependent edema, dyspnea, or a new cardiac murmur. If present, notify prescriber and expect drug to be discontinued.
- Use caution when administering lorcaserin to men who have conditions that might predispose them to priapism (e.g., leukemia, multiple myeloma, or sickle cell anemia), or in men with anatomical deformation of the penis (e.g., angulation, cavernosal fibrosis, or Peyronie's disease) because priapism is a potential effect of 5-HT<sub>2C</sub> receptor agonism.
- Use lorcaserin cautiously in patients with bradycardia or a history of heart block greater than first degree because a decrease in heart rate may occur with lorcaserin therapy.
- Use lorcaserin cautiously in patients with moderate renal impairment or severe hepatic impairment because the effects of lorcaserin in these patients are unknown. The drug is not recommended for patients with severe renal impairment or end-stage renal disease.
- Be aware that daily dosage should not exceed 10 mg twice a day for immediate-release formulation and 20 mg once daily for extended-release formulation, because of increased risk of psychiatric disorders such as dissociation, euphoria, or hallucinations.
- Assess patient's weight loss at the end of 12 weeks. If patient has not lost at least 5% of his baseline body weight, notify prescriber and expect lorcaserin to be discontinued, as no further benefits are likely.

**WARNING** Monitor patient for signs and symptoms of serotonin syndrome, which may include autonomic instability (e.g., hyperthermia, labile blood pressure, tachycardia), gastrointestinal symptoms (e.g., diarrhea, nausea, vomiting), mental status changes (e.g., agitation, coma, hallucinations), and/or neuromuscular aberrations (e.g., hyperreflexia, incoordination). Know that serotonin syndrome, in its most severe form, can resemble neuroleptic malignant syndrome, which

includes autonomic instability with possible rapid fluctuation of vital signs, hyperthermia, mental status changes, and muscle rigidity. If present, discontinue lorcaserin immediately, notify prescriber, and provide supportive care.

- Monitor patient's blood glucose level, especially patient with type 2 diabetes mellitus who is also being treated with insulin and/or oral hypoglycemic agents. As weight is lost, the risk of hypoglycemia increases. If hypoglycemia develops, treat appropriately and notify prescriber, as a dosage reduction may be needed with the patient's antidiabetic drug regimen.
- Monitor patient's complete blood count (CBC) periodically, as ordered, as hematological changes may occur during lorcaserin therapy.
- Monitor patient for signs and symptoms of prolactin excess (e.g., galactorrhea, gynecomastia) because lorcaserin moderately elevates prolactin levels. If present, notify prescriber and expect to obtain a prolactin level to confirm.
- Monitor patient for emergence or worsening of depression, suicidal behavior or thoughts, and/or any unusual changes in behavior or mood, because some drugs such as lorcaserin that target the central nervous system may be associated with depression or suicidal ideation. Monitor patient closely and expect drug to be discontinued if patient experiences suicidal behavior or thoughts.

## **PATIENT TEACHING**

- Warn patient not to exceed prescribed dosage because serious adverse effects may occur.
- Instruct patient prescribed extended-release form that tablet must be swallowed whole and must not be chewed, crushed, or divided.
- Tell patient using drug for weight loss that drug is not a replacement for a diet and exercise regimen. Instruct patient to stop drug after 12 weeks if patient has not achieved a 5% weight loss.
- Advise patient to avoid hazardous activities until drug's CNS effects on cognition are known.
- Instruct patient with type 2 diabetes mellitus who is also taking insulin or an oral hypoglycemic agent to monitor his blood glucose level closely. If

hypoglycemia develops, tell him to notify prescriber, as a dosage adjustment of his antidiabetic agent(s) may be needed.

- Inform a male patient to seek emergency care if he develops a painful erection that lasts longer than 4 hours and to discontinue lorcaserin therapy immediately.
- Instruct patient to tell prescriber of all medications being taken, including over-the-counter drugs and any weight loss products.
- Advise patient to inform prescriber of any persistent, severe, or unusual signs and symptoms.
- Tell women of childbearing age to notify prescriber immediately if pregnancy is suspected or has occurred.
- Inform mothers that breastfeeding is not recommended, because of the risk for serious adverse reactions in a breastfed infant.
- Caution family and caregivers to monitor patient for emergence or worsening of depression, suicidal behavior or thoughts, and/or any unusual changes in behavior or mood. If present, urge them to contact prescriber immediately.

## losartan potassium

**Cozaar**

### Class and Category

*Pharmacologic class:* Angiotensin II receptor blocker (ARB)

*Therapeutic class:* Antihypertensive

### Indications and Dosages

➤ *To manage hypertension*

**SUSPENSION, TABLETS**

**Adults.** *Initial:* 50 mg daily. *Maintenance:* 25 to 100 mg as a single dose or in 2 divided doses.

**Children age 6 and over with an estimated glomerular filtration rate 30 ml/min or greater.** *Initial:* 0.7 mg/kg (up to 50 mg total) once daily, with dosage adjusted, as needed. *Maximum:* 1.4 mg/kg or 100 mg daily.

- *To treat nephropathy in patients with type 2 diabetes and hypertension*

## SUSPENSION, TABLETS

**Adults.** *Initial:* 50 mg daily, increased to 100 mg daily, as needed.

- *To reduce stroke risk in patients with hypertension and left ventricular hypertrophy*

## SUSPENSION, TABLETS

**Adults.** *Initial:* 50 mg daily, followed by 12.5 mg hydrochlorothiazide daily. Dosage increased to 100 mg daily, as needed, followed by 25 mg hydrochlorothiazide daily, as needed.

***DOSAGE ADJUSTMENT*** Initial losartan dosage reduced to 25 mg daily for patients with impaired hepatic function or volume depletion.

Route	Onset	Peak	Duration
P.O.	Unknown	6 hr	Over 24 hr

## Mechanism of Action

Blocks binding of angiotensin II to receptor sites in many tissues, including adrenal glands and vascular smooth muscle. Angiotensin II is a potent vasoconstrictor that also

stimulates the adrenal cortex to secrete aldosterone. The inhibiting effects of angiotensin II reduce blood pressure.

Decreases left ventricular mass index in patients with left ventricular hypertrophy who also have hypertension. By targeting the renin-angiotensin system, a renoprotective action occurs through the lowering of the albumin excretion rate in patients with type 2 diabetes.

## **Contraindications**

Concurrent aliskiren therapy (in patients with diabetes), hypersensitivity to losartan or its components

## **Interactions**

### **DRUGS**

*ACE inhibitors, aliskiren (in patients with diabetes or renal impairment with a glomerular filtration rate less than 60 ml/min), other angiotensin receptor blockers:* Increased risk of hyperkalemia, hypotension, and renal dysfunction  
*lithium:* Increased serum lithium levels and risk of lithium toxicity

*NSAIDs:* Possibly decreased renal function in elderly patients or those with renal dysfunction or volume depletion; possibly decreased effectiveness of losartan

*potassium-sparing diuretics, potassium supplements:* Increased risk of hyperkalemia

### **FOODS**

*high-potassium diet, potassium-containing salt substitutes:* Increased risk of hyper-kalemia

## **Adverse Reactions**

**CNS:** Dizziness, fatigue, headache, insomnia, malaise

**CV:** **Hypotension**

**EENT:** Nasal congestion

**GI:** Diarrhea, indigestion, nausea, vomiting

**HEME:** **Thrombocytopenia**

**MS:** Back pain, leg pain, muscle spasms

**RESP:** Cough, upper respiratory tract infection

**SKIN:** Erythroderma

**Other:** **Angioedema, hyperkalemia, hyponatremia**

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm and should be discontinued as soon as pregnancy is known.
- Drug given during the second or third trimester reduces fetal renal function and increases fetal and neonatal morbidity and death. Resulting oligohydramnios can cause fetal lung hypoplasia and skeletal malformations.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that in some patients, losartan is more effective when given in 2 divided doses daily; it may be used with other antihypertensives.
- Know that patients of African descent with hypertension and left ventricular hypertrophy may not benefit from losartan to reduce stroke risk.

**WARNING** Be aware that patients who have renal artery stenosis or severe heart failure may experience acute renal failure from losartan therapy because losartan inhibits the angiotensin-aldosterone system, on which renal function depends.

- Monitor blood pressure and renal function studies, as ordered, to evaluate drug effectiveness.
- Periodically monitor patient's serum potassium level, as ordered, to detect hyperkalemia.
- Monitor patient for muscle pain; rarely, rhabdomyolysis has developed in patients taking other angiotensin II receptor blockers.

## **PATIENT TEACHING**

- Instruct patient to avoid potassium-containing salt substitutes because they may increase risk of hyperkalemia.
- Advise patient to avoid exercising in hot weather and drinking excessive amounts of alcohol; instruct her to notify prescriber if she has prolonged diarrhea, nausea, or vomiting.
- Warn patient to tell all prescribers of losartan therapy.
- Instruct women to notify prescriber immediately if pregnancy occurs or is suspected as drug may cause fetal harm and will need to be discontinued.

**lovastatin**

**(mevinolin)**

**Altoprev**

## **Class and Category**

*Pharmacologic class:* HMG-CoA reductase inhibitor (statin)  
*Therapeutic class:* Antilipemic

## Indications and Dosages

- *To reduce LDL and total cholesterol levels in patients with primary hypercholesterolemia; to reduce risk of coronary revascularization procedures, myocardial infarction, or unstable angina in patients without symptomatic cardiovascular disease and who have average to moderately elevated total-C and LDL-C, and below average HDL-C as primary prevention of coronary heart disease; to slow progression of coronary atherosclerosis in patients with coronary heart disease*

### **TABLETS**

**Adults.** *Initial:* 20 mg as a single dose with evening meal for LDL-C reduction of 20% or more, 10 mg daily for LDL-C reduction of less than 20%; dosage adjusted after at least 4 wk. *Maintenance:* 10 to 80 mg daily as a single dose or in 2 divided doses with meals. *Maximum:* 80 mg daily.

### **E.R. TABLETS (ALTOPREV)**

**Adults.** *Initial:* 20, 40, or 60 mg as single dose at bedtime, increased, as needed, every 4 wk, up to maximum dose. *Maintenance:* 20 to 60 mg daily as single dose. *Maximum:* 60 mg daily.

- *To reduce apolipoprotein B, LDL, and total cholesterol levels in adolescents with heterozygous familial hypercholesterolemia*

### **TABLETS**

**Adolescents 1 yr postmenarche (ages 10 to 17).** *Initial:* 20 mg daily with evening meal for LDL-C reduction of 20% or more, 10 mg daily for LDL-C reduction of less than 20%; dosage adjusted after at least 4 wk. *Maintenance:* 10 to 40 mg daily. *Maximum:* 40 mg daily.

**DOSAGE ADJUSTMENT** For patients who also take amiodarone, maximum dosage limited to 40 mg daily. For patients who also take danazol, diltiazem, dronedarone, or verapamil, initial therapy begun at 10 mg daily and maximum dosage limited to 20 mg daily. For patients with creatinine clearance less than 30 ml/min, maximum dosage limited to 20 mg daily or increased, if needed, very carefully.

Route	Onset	Peak	Duration
P.O.	In 2 wk	Unknown	4–6 wk

## Mechanism of Action

Interferes with the hepatic enzyme hydroxymethylglutaryl-coenzyme A reductase. By doing so, lovastatin reduces formation of mevalonic acid (a cholesterol precursor), thus interrupting the pathway by which cholesterol is synthesized. When cholesterol level declines in hepatic cells, LDLs are consumed, which also reduces amount of circulating total cholesterol and serum triglycerides. The decrease in LDLs may result in decreased level of apolipoprotein B, which is found in each LDL particle.

## Contraindications

Acute hepatic disease; breastfeeding; concomitant therapy with cobicistat-containing products or strong CYP3A4 inhibitors (such as boceprevir, clarithromycin, erythromycin, HIV protease inhibitors, itraconazole, ketoconazole, nefazodone, posaconazole, telaprevir,

telithromycin, voriconazole); hypersensitivity to lovastatin or its components; pregnancy; unexplained elevated liver enzymes

## **Interactions**

### **DRUGS**

*amiodarone, boceprevir, cobicistat-containing products, clarithromycin, colchicine, cyclosporine, danazol, diltiazem, dronedarone, erythromycin, fibric acid derivatives, gemfibrozil and other fibrates, HIV protease inhibitors, itraconazole, ketoconazole, nefazodone, niacin (1 g daily or more), posaconazole, ranolazine, telaprevir, telithromycin, verapamil, voriconazole:* Increased risk of severe myopathy or rhabdomyolysis

*oral anticoagulants:* Increased anticoagulant effect and risk of bleeding

### **FOODS**

*grapefruit juice (more than 1 qt daily):* Increased risk of myopathy or rhabdomyolysis

### **ACTIVITIES**

*alcohol use:* Increased lovastatin blood level

## **Adverse Reactions**

**CNS:** Anxiety, asthenia, cognitive impairment, chills, confusion, cranial nerve dysfunction, depression, dizziness, fatigue, fever, headache, insomnia, malaise, memory loss, paresthesia, peripheral nerve palsy, peripheral neuropathy, psychic disturbances, tremor, vertigo

**CV:** Vasculitis

**EENT:** Blurred vision, cataracts, ophthalmoplegia, pharyngitis, rhinitis, sinusitis

**ENDO:** Elevated glycosylated hemoglobin levels, gynecomastia, hyperglycemia, thyroid function abnormalities

**GI:** Abdominal cramps and pain, anorexia, cholestatic jaundice, **cirrhosis**, constipation, diarrhea, elevated liver enzymes, flatulence, **fulminant hepatic necrosis**, **hepatic failure** (rare), **hepatitis**, hyperbilirubinemia, indigestion, nausea, hepatoma, **pancreatitis**, vomiting

**GU:** Erectile dysfunction, loss of libido

**HEME:** Elevated ESR, eosinophilia, **hemolytic anemia**, **leukopenia**, positive ANA, purpura, **thrombocytopenia**

**MS:** Arthralgias, arthritis, back pain, immune-mediated necrotizing myopathy, muscle pain, myalgia, myopathy, myositis, polymyalgia rheumatica, **rhabdomyolysis**

**RESP:** Cough, dyspnea, **interstitial lung disease**, upper respiratory tract infection

**SKIN:** Alopecia, changes to hair and nails, dermatomyositis, discolored or dry skin, **erythema multiforme**, flushing, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, elevated alkaline phosphatase, lupus erythematosus-like syndrome

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm according to animal studies.
- Drug is contraindicated in pregnancy because there is no apparent benefit to drug therapy in pregnancy and it may cause fetal harm.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Drug is contraindicated in breastfeeding.

## **REPRODUCTION**

- Women of childbearing age should be advised to use effective contraception during drug treatment.

## **Nursing Considerations**

- Give lovastatin cautiously in patients who have a history of liver disease and patients who consume large amounts of alcohol.
- Give drug 1 hour before or 4 hours after bile acid sequestrant, cholestyramine, or colestipol.
- Expect patient to be prescribed a standard low-cholesterol diet during therapy.
- Be aware that drug affects mainly total cholesterol and LDL levels; it has only slight effects on HDL and triglyceride levels.
- Monitor liver enzymes before therapy begins, as ordered. If indicated, expect to measure them during therapy, as ordered. If ALT or AST level reaches or exceeds three times upper limit of normal and persists at that level, expect to discontinue lovastatin.
- Monitor patient closely for muscle pain, tenderness, or weakness suggestive of myopathy. Also monitor creatinine kinase, as ordered. If patient becomes symptomatic or creatine kinase becomes highly elevated, withhold drug, notify prescriber and expect drug to be discontinued. Be especially alert for myopathy that could become its more severe form, rhabdomyolysis, in patients with other disorders such as diabetes complicated with renal dysfunction.
- Expect to withhold drug temporarily in patients who develop an acute or serious condition predisposing the patient to the development of renal failure secondary to rhabdomyolysis. Conditions to be watchful for include hypotension; major surgery or trauma; sepsis; or severe electrolyte, endocrine, or metabolic disorders; or uncontrolled epilepsy. Be mindful that the drug interactions may not be the same for the extended-release

formulation of lovastatin as for those encountered with the immediate-release formulation.

## **PATIENT TEACHING**

- Tell patient who takes drug once daily to do so with evening meal to enhance absorption.
- Advise patient to report muscle aches, pains, tenderness, or weakness, being especially watchful of these symptoms when dosage is increased. If present, tell him to stop taking lovastatin immediately and notify prescriber.
- Instruct patient to report severe GI distress or vision changes, as well as the development of dark urine, fatigue, loss of appetite, right upper abdominal pain or yellowing of skin.
- Advise patient to avoid performing any hazardous activity, such as driving, if cognitive impairment develops and to notify prescriber.
- Tell patient to alert prescriber of any over-the-counter or prescription drugs being taken because serious drug interactions could occur.
- Urge patient to avoid consuming alcohol or more than 1 quart of grapefruit juice daily while taking drug.
- Direct patient to follow a low-cholesterol diet during therapy. Recommend exercise and weight loss programs as appropriate.
- Emphasize the importance of periodic eye examinations during therapy.
- Teach female patients appropriate contraceptive methods and the need to report suspected pregnancy immediately.
- Tell mothers that breastfeeding is contraindicated while taking lovastatin.

**lubiprostone**

**Amitiza**

## **Class and Category**

*Pharmacologic class:* Chloride channel activator  
*Therapeutic class:* GI motility

## Indications and Dosages

- *To treat chronic idiopathic constipation; to treat opioid-induced constipation in patients with chronic noncancer pain*

### CAPSULES

**Adults.** 24 mcg twice daily.

- *To treat irritable bowel syndrome with constipation*

### CAPSULES

**Women at least 18 years of age.** 8 mcg twice daily.

***DOSAGE ADJUSTMENT*** For patients with chronic idiopathic constipation or opioid-induced constipation who have moderate liver impairment, dosage reduced to 16 mcg twice daily. For patients being treated for any listed indication who have severe liver impairment, dosage reduced to 8 mcg once daily.

## Mechanism of Action

Enhances a chloride-rich intestinal fluid secretion specifically by activating CIC-2, which is a normal constituent of the apical membrane of the human intestine. By increasing intestinal fluid secretion, motility in the intestine is increased, which facilitates the passage of stool to alleviate the symptoms associated with chronic idiopathic constipation. In addition, activation of the apical CIC-2 channels in intestinal epithelial cells bypasses the antisecretory action of opiates through suppression of secretomotor neuron excitability.

# Contraindications

Hypersensitivity to lubiprostone or its components,  
mechanical gastrointestinal obstruction

# Interactions

## DRUGS

*diphenylheptaine opioids such as methadone*: Decreased effectiveness of lubiprostone

# Adverse Reactions

**CNS:** Anxiety, asthenia, depression, dizziness, fatigue, headache, lethargy, malaise, syncope, tremor

**CV:** Chest discomfort or pain, **hypotension**, palpitations, peripheral edema, tachycardia

**EENT:** Distortion of sense of smell, dry mouth, pharyngolaryngeal pain, **throat tightness**

**GI:** Abdominal distention or pain, anorexia, constipation, defecation urgency, diarrhea, dyspepsia, elevated liver enzymes, eructation, fecal incontinence, flatulence, frequent bowel movements, gastritis, gastroesophageal reflux disease, intestinal functional disorder, **ischemic colitis**, nausea, **rectal hemorrhage**, vomiting

**GU:** Pollakiuria, UTI

**MS:** Fibromyalgia, joint swelling, muscle cramps or spasms, myalgia

**RESP:** Cough, dyspnea

**SKIN:** Cold sweat, erythema, excessive diaphoresis, rash

**Other:** Flu-like symptoms, generalized pain, **hypokalemia**, swelling, weight gain

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for diarrhea.

# Nursing Considerations

- Be aware that lubiprostone should not be given to patients with severe diarrhea. If severe diarrhea occurs while patient is taking drug, notify prescriber and expect drug to be discontinued.
- Administer lubiprostone with food and water to reduce nausea.
- Monitor patient's blood pressure for hypotension. Syncope and hypotension have occurred with lubiprostone therapy and sometimes within 1 hour after drug administration, including the first dose. Risk factors include the presence of diarrhea or vomiting or taking drugs known to lower blood pressure.
- Assess patient for dyspnea, which generally has occurred as an acute onset within 30 to 60 minutes after being given the first dose of lubiprostone. Although dyspnea usually resolves within 3 hours after taking drug, it may reoccur with subsequent doses. If it becomes severe or reoccurs, notify prescriber.

## PATIENT TEACHING

- Instruct patient to swallow capsules whole and not to break apart or chew the capsules.

- Tell patient to take lubiprostone with food and water.
- Inform patient of the possibility of diarrhea occurring with lubiprostone therapy. If diarrhea becomes severe, tell patient to stop taking drug and notify prescriber.
- Tell patient that drug may lower his blood pressure to the point of fainting. Caution patient to avoid performing hazardous activities until the effects of drug are known.
- Instruct patient to inform all prescribers of lubiprostone therapy, because drugs known to lower blood pressure increase patient's risk of low blood pressure and possibly fainting.
- Alert patient that difficulty breathing may occur after the first dose of lubiprostone but generally resolves within 3 hours. Tell patient to notify prescriber if dyspnea occurs.
- Tell mothers who are breastfeeding while taking lubiprostone to monitor the infant for diarrhea.

## lumateperone

### Caplyta

## Class and Category

*Pharmacologic class:* Neuroleptic

*Therapeutic class:* Atypical antipsychotic

## Indications and Dosages

➤ *To treat schizophrenia*

### CAPSULES

**Adults.** 42 mg once daily with food.

# Mechanism of Action

Although exact mechanism is unknown, drug may be mediated through a combination of antagonist activity of central serotonin 5-HT<sub>2A</sub> receptors and postsynaptic antagonist activity at central dopamine D<sub>2</sub> receptors.

# Contraindications

Hypersensitivity to lumateperone or its components

# Interactions

## DRUGS

*CYP3A4 inducers:* Decreased exposure and effectiveness of lumateperone

*Moderate to strong CYP3A4 inhibitors, UGT inhibitors:* Increased exposure and risk of adverse reactions to lumateperone

# Adverse Reactions

**CNS:** Body temperature dysregulation, cognitive and motor impairment, dizziness, dystonia, extrapyramidal symptoms, fatigue, **neuroleptic malignant syndrome**, **seizures**, syncope, tardive dyskinesia

**CV:** Dyslipidemia, orthostatic hypotension

**EENT:** Dry mouth

**ENDO:** Hyperglycemia

**GI:** Anorexia, dysphagia, nausea, vomiting

**HEME:** **Agranulocytosis**, **leukopenia**, **neutropenia**

**MS:** Elevated creatine phosphokinase levels

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry>.
- Drug may cause fetal harm if fetus is exposed to drug during the third trimester, as extrapyramidal and/or withdrawal symptoms may occur after delivery.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## REPRODUCTION

- Drug may impair female and male fertility.

# Nursing Considerations

**WARNING** Know that lumateperone shouldn't be used in elderly patients with dementia-related psychosis because drug increases risk of death in these patients. Also, know that lumateperone should not be given to patients with moderate or severe hepatic impairment or to patients taking CYP3A4 inducers or moderate to strong CYP3A4 inhibitors.

- Use lumateperone cautiously in patients at risk for aspiration because drug may cause dysphagia.

**WARNING** Monitor patient for signs and symptoms of neuroleptic malignant syndrome (autonomic instability, delirium, hyperpyrexia, muscle rigidity) and report any such effects to prescriber immediately. Expect lumateperone to be discontinued and appropriate intensive treatment instituted, as prescribed.

- Notify prescriber if patient develops tardive dyskinesia, as the risk it will become irreversible increases with duration of treatment and cumulative dose. Be aware that tardive dyskinesia can develop after only a relatively brief treatment period, even at low doses, and it may occur after drug has been discontinued.
- Monitor patient's blood glucose and lipid levels as well as weight because drug may cause metabolic changes such as hyperglycemia, dyslipidemia, and weight gain.

**WARNING** Monitor patient with clinically significant neutropenia for fever or other signs of infection and report promptly. Expect to monitor patient's complete blood count during drug therapy. Know that lumateperone should be discontinued if patient's absolute neutrophil count falls to less than 1,000/mm<sub>3</sub>.

- Assess patient for orthostatic hypotension, especially elderly patients; patients with concomitant treatment with antihypertensive drugs, dehydration, or hypovolemia; patients with known cardiovascular disease; and patients with cerebrovascular disease.
- Institute fall precautions, because lumateperone may cause motor and sensory instability, postural hypotension, and somnolence, which may lead to falls.
- Institute seizure precautions, as lumateperone may cause seizures.

## **PATIENT TEACHING**

- Encourage patient to inform all prescribers of lumateperone therapy and any other drugs taken, including over-the-counter and herbal products.

- Instruct patient to rise from a lying or sitting position slowly, especially early in drug therapy and when drug is being reinitiated, to avoid a drop in blood pressure. Inform patient that hot tubs, prolonged hot showers, and saunas may worsen this effect.
- Review signs and symptoms of infection with patient and stress importance of reporting a suspected infection to prescriber.
- Encourage patient to monitor weight and report excessive weight gain. Also inform patient that drug may increase blood glucose and lipid levels. Review signs and symptoms of hyperglycemia with patient and stress importance of complying with laboratory testing for these metabolic alterations.
- Review signs and symptoms of tardive dyskinesia and tell patient to report these abnormal movements, if present.

**WARNING** Review signs and symptoms of neuroleptic malignant syndrome with patient and family. Urge patient to seek emergency care if present.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Advise women of childbearing age that fetal harm may occur in the third trimester and to notify prescriber if pregnancy is suspected or known. Also alert pregnant women that breastfeeding is not recommended during lurasidone therapy.
- Inform patient that drug may impair fertility.

## **lurasidone hydrochloride**

**Latuda**

### **Class and Category**

*Pharmacologic class:* Atypical antipsychotic

*Therapeutic class: Antipsychotic*

## Indications and Dosages

- *To treat schizophrenia*

### **TABLETS**

**Adults.** *Initial:* 40 mg once daily (with a meal consisting of at least 350 calories), increased as needed. *Maximum:* 160 mg once daily.

**Adolescents ages 13 to 17.** *Initial:* 40 mg once daily (with a meal consisting of at least 350 calories), increased as needed. *Maximum:* 80 mg daily.

- *To treat depressive episodes associated with bipolar I disorder as monotherapy or adjunctive therapy with either lithium or valproate*

### **TABLETS**

**Adults.** *Initial:* 20 mg once daily (with a meal consisting of at least 350 calories), increased as needed. *Maximum:* 120 mg once daily.

- *To treat depressive episodes associated with bipolar I disorder as monotherapy*

### **TABLETS**

**Children age 10 to 17 years.** *Initial:* 20 mg once daily (with a meal consisting of at least 350 calories), increased weekly, after one week, as needed. *Maximum:* 80 mg daily.

***DOSAGE ADJUSTMENT*** For patients already taking a moderate CYP3A4 drug or who have moderate hepatic impairment or moderate (creatinine clearance 30 to less than 50 ml/min) or severe (creatinine clearance less than 30 ml/min) renal impairment, initial dosage reduced to 20 mg daily and

maximum dose should not exceed 80 mg once daily. For patient with severe hepatic impairment, initial dosage reduced to 20 mg daily and maximum dose should not exceed 40 mg once daily. For patient newly prescribed a moderate CYP3A4 inhibitor, dosage reduced to half of the original dose of lurasidone prescribed. For patient receiving a moderate CYP3A4 inducer, dosage may have to be increased after CYP3A4 inducer therapy has been in place for at least 7 days.

## **Mechanism of Action**

Possibly mediated through a combination of central dopamine type 2 and serotonin type 2 receptor antagonism to suppress psychotic symptoms.

## **Contraindications**

Concurrent therapy with strong CYP3A4 inducers such as avasimibe, carbamazepine, phenytoin, rifampin or St. John's wort; concurrent therapy with strong CYP3A4 inhibitors such as clarithromycin, ketoconazole, mibefradil, ritonavir, or voriconazole; hypersensitivity to lurasidone or its components

## **Interactions**

### **DRUGS**

*CYP3A4 inducers:* Possibly decreased effect of lurasidone

*CYP3A4 inhibitors:* Possibly increased effect of lurasidone

## **Adverse Reactions**

**CNS:** Agitation, akathisia, anxiety, **CVA**, dizziness, dystonia, extrapyramidal symptoms, fatigue, hypomania or mania activation, impaired cognitive and motor function, insomnia, **neuroleptic malignant syndrome**, parkinsonism, psychomotor hyperactivity, restlessness, **seizures**, somnolence, **suicidal ideation**, syncope, tardive dyskinesia, transient ischemic attacks

**CV:** Hypertension, orthostatic hypotension, tachycardia

**EENT:** Blurred vision, dry mouth, increased salivation, oropharyngeal pain, rhinitis, **throat swelling**, tongue swelling

**ENDO:** Hyperglycemia, hyperprolactinemia

**GI:** Abdominal pain, anorexia, diarrhea, dyspepsia, dysphagia, nausea, vomiting

**GU:** Elevated creatinine level

**HEME:** **Agranulocytosis**, **leukopenia**, **neutropenia**

**MS:** Back pain, **rhabdomyolysis**

**RESP:** Dyspnea

**SKIN:** Pruritus, rash, urticaria

**Other:** Elevated CPK level, **hyponatremia**, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- Drug may cause fetal harm. Neonates exposed to the drug in the third trimester of pregnancy are at risk for extrapyramidal and/or withdrawal symptoms following delivery.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Be aware that lurasidone should not be used to treat dementia-related psychosis in the elderly because of an increased risk of death nor in patients at risk for aspiration pneumonia because drug may cause esophageal dysmotility, resulting in dysphagia.

- Use lurasidone cautiously in patients with cardiovascular disease, cerebrovascular disease, or conditions that would predispose them to hypotension. Also, use cautiously in those with a history of seizures or with conditions that lower the seizure threshold, such as Alzheimer's disease.
- Also, use cautiously in elderly patients because of increased risk of serious adverse cerebrovascular effects, such as stroke and transient ischemic attack.

**WARNING** Monitor patient closely for neuroleptic malignant syndrome, seizures, and tardive dyskinesia throughout therapy, and take safety precautions, as needed. Notify prescriber immediately of any occurrence.

- Monitor patient's blood glucose level routinely; risk of hyperglycemia may increase.
- Watch patients closely for suicidal tendencies, especially in children and young adults, and particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, and neutropenia. Assess more often during first few months of therapy if patient has a history of drug-induced leukopenia or neutropenia or a significantly low WBC count. If abnormalities occur during therapy, watch for fever or other signs of infection, notify prescriber, and, if severe, expect drug to be discontinued.

- Know that extrapyramidal symptoms and withdrawal symptoms may occur in newborns following delivery to mothers taking lurasidone during the third trimester.
- Be aware that the occurrence of tardive dyskinesia and the chances of the dyskinesia being irreversible increase the longer therapy continues, as well as with the total cumulative dose. Although less common, tardive dyskinesia may also occur after relatively short periods of therapy at low doses and may even occur after therapy has been discontinued. Monitor patient closely and notify prescriber at once if present.
- Assess patient for fall risk and institute fall precautions.

## **PATIENT TEACHING**

- Instruct patient or caregiver that lurasidone must be taken with a meal consisting of at least 350 calories.
- Urge patient to avoid alcohol during lurasidone therapy.
- Instruct patient to avoid hazardous activities until drug's effects are known. Warn patient that falls can also occur due to the effects of drug on the nervous system. Review fall precautions with patient.
- Caution patient to avoid dehydration, exercising strenuously, exposure to extreme heat or taking medication with anticholinergic activity because lurasidone therapy may interfere with being able to reduce the body's core body temperature.

**magnesium oxide**

**Mag-200, Mag-Ox 400, Maox, Uro-Mag**

**magnesium sulfate**

## **Class and Category**

*Pharmacologic class:* Mineral

*Therapeutic class:* Electrolyte replacement

## **Indications and Dosages**

- *To correct magnesium deficiency caused by alcoholism, magnesium-depleting drugs, malnutrition, or restricted diet; to prevent magnesium deficiency based on U.S. and Canadian recommended daily allowances*

**CAPSULES, CHEWABLE TABLETS, CRYSTALS, ENTERIC-COATED TABLETS, E.R. TABLETS, LIQUID, LIQUID CONCENTRATE, ORAL SOLUTION, TABLETS (MAGNESIUM CHLORIDE, CITRATE, GLUCONATE, HYDROXIDE, LACTATE [EXCEPT IN CHILDREN], OXIDE, SULFATE)**

Dosage individualized based on severity of deficiency and normal recommended daily allowances listed below.

**Adult men and children over age 10.** 270 to 400 mg daily (*Canada*: 130 to 250 mg daily).

**Adult women and children over age 10.** 280 to 300 mg daily (*Canada*: 135 to 210 mg daily).

**Pregnant women.** 320 mg daily (*Canada*: 195 to 245 mg daily).

**Breastfeeding women.** 340 to 355 mg daily (*Canada*: 245 to 265 mg daily).

**Children ages 7 to 10.** 170 mg daily (*Canada*: 100 to 135 mg daily).

**Children ages 4 to 6.** 120 mg daily (*Canada*: 65 mg daily).

**Children from birth to age 3.** 40 to 80 mg/day (*Canada*: 20 to 50 mg daily).

➤ *To treat mild magnesium deficiency*

## **I.M. INJECTION (MAGNESIUM SULFATE)**

**Adults and adolescents.** 1 g every 6 hr for 4 doses.

➤ *To treat severe hypomagnesemia*

## **I.V. INFUSION (MAGNESIUM CHLORIDE)**

**Adults.** 4 g diluted in 250 ml D<sub>5</sub>W and infused at no more than 3 ml/min. *Maximum*: 40 g daily.

## **I.V. INFUSION (MAGNESIUM SULFATE)**

**Adults and adolescents.** 5 g diluted in 1 L I.V. solution and infused over 3 hr.

➤ *To prevent and control seizures in preeclampsia or eclampsia*

## **I.M. INJECTION, I.V. INFUSION OR INJECTION (MAGNESIUM SULFATE)**

**Adults.** *Loading:* 4 g of a 10% to 20% solution and given I.V. very slowly following manufacturer's guidelines for type of solution used. Simultaneously up to 10 g I.M. *Maintenance required for some patients:* 1 to 2 g/hr by continuous infusion. *Maximum:* 40 g/day and for no longer than 5 to 7 days.

➤ *To treat acute nephritis in children*

## **I.M. INJECTION (MAGNESIUM SULFATE)**

Children. 20 to 40 mg/kg of a 20% solution, repeated as needed.

➤ *To treat torsades de pointes*

## **I.V. INFUSION**

**Adults.** *For patient with pulse:* 1 to 2 g diluted in 50 to 100 ml D5W and infused over 5 to 60 min, followed by 0.5 to 1 g/hr. *For patient in cardiac arrest:* 1 to 2 g diluted in 10 ml D5W and infused over 5 to 20 min.

➤ *To relieve indigestion with hyperacidity*

## **CHEWABLE TABLETS, LIQUID, LIQUID CONCENTRATE, ORAL SOLUTION TABLETS (MAGNESIUM HYDROXIDE)**

**Adults and adolescents.** 400 to 1,200 mg (5 to 15 ml liquid or 2.5 to 7.5 ml liquid concentrate) up to four times daily with water, or 622 to 1,244 mg (tablets or chewable tablets) up to four times daily.

## **CAPSULES, TABLETS (MAGNESIUM OXIDE)**

**Adults and adolescents.** 140 mg (capsules) three times daily or four times daily with water or milk, or 400 to 800 mg (tablets) daily.

- *To relieve constipation, to evacuate colon for rectal or bowel examination*

## **LIQUID, LIQUID CONCENTRATE (MAGNESIUM HYDROXIDE)**

**Adults and children age 12 and over.** 2.4 to 4.8 g (30 to 60 ml) daily as single dose at bedtime or divided doses.

**Children ages 6 to 11.** 1.2 to 2.4 g (15 to 30 ml)/day as a single dose or in divided doses.

**Children ages 2 to 5.** 0.4 to 1.2 g (5 to 15 ml) daily as single dose or divided doses.

## **ORAL SOLUTION (MAGNESIUM CITRATE)**

**Adults and children age 12 and over.** Up to 10 ounces with 8 ounces of water as a single dose or in divided doses.

**Children ages 6 to 11.** Up to 5 ounces with 8 ounces of water.

**Children ages 2 to 5.** Highly individualized.

## **CRYSTALS (MAGNESIUM SULFATE)**

**Adults and children age 12 and over.** 10 to 30 g daily with 8 ounces of water as single dose or divided doses.

*Maximum: Two times daily.*

**Children age 6 to 12.** 5 to 10 g with 8 ounces of water as a single dose or divided doses.

***DOSAGE ADJUSTMENT*** Dosage limited to 20 g of magnesium sulfate every 48 hr for patients with severe renal impairment.

---

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.*	0.5–3 hr	Unknown	Unknown
P.O.†	20 min	Unknown	20–180 min

Route	Onset	Peak	Duration
I.M. <sup>‡</sup>	1 hr	Unknown	3–4 hr
I.V. <sup>‡</sup>	Immediate	Unknown	About 30 min

\* For laxative effect.

† For antacid effect.

‡ For anticonvulsant effect.

## Mechanism of Action

Assists all enzymes involved in phosphate transfer reactions that use adenosine triphosphate (ATP). Magnesium is required for normal function of the ATP-dependent sodium–potassium pump in muscle membranes. It may effectively treat digitalis glycoside-induced arrhythmias because correction of hypomagnesemia improves the sodium–potassium pump’s ability to distribute potassium into intracellular spaces and because magnesium decreases calcium uptake and potassium outflow through myocardial cell membranes.

As a laxative, magnesium exerts a hyperosmotic effect in the small intestine. It causes water retention that distends the bowel and causes the duodenum to secrete cholecystokinin. This substance stimulates fluid secretion and intestinal motility.

As an antacid, magnesium reacts with water, converting magnesium oxide to magnesium hydroxide. Magnesium hydroxide rapidly reacts with gastric acid to form water and magnesium chloride, which increases gastric pH.

As an anticonvulsant, magnesium depresses the CNS and blocks peripheral neuromuscular impulse transmission by decreasing available acetylcholine.

## Incompatibilities

Don't combine magnesium sulfate with alkali carbonates and bicarbonates, alkali hydroxides, arsenates, calcium, clindamycin phosphate, dobutamine, fat emulsions, heavy metals, hydrocortisone sodium succinate, phosphates, polymyxin B, procaine hydrochloride, salicylates, sodium bicarbonate, strontium, and tartrates.

## Contraindications

Hypersensitivity to magnesium salts or any component of magnesium-containing preparations

*For magnesium chloride:* Coma, marked heart disease, renal impairment

*For magnesium sulfate:* Heart block, MI, preeclampsia 2 hours or less before delivery (I.V. form)

*For use as laxative:* Acute abdominal problem (as indicated by abdominal pain, nausea, or vomiting), diverticulitis, fecal impaction, intestinal obstruction or perforation, colostomy or ileostomy, severe renal impairment, ulcerative colitis

## Interactions

### DRUGS

*oral drugs:* Possibly decreased absorption of oral drugs when magnesium salts given orally

*calcium salts (I.V.):* Possibly neutralization of magnesium sulfate's effects

*calcium channel blockers:* Possibly enhanced adverse/toxic effects of magnesium salts

*CNS depressants:* Increased CNS depression

*digoxin:* Possibly heart block and conduction changes

*misoprostol:* Increased misoprostol-induced diarrhea

*neuromuscular blockers*: Possibly increased neuromuscular blockade

*sodium polystyrene sulfonate resin*: Possibly metabolic alkalosis

## **FOODS**

*high glucose intake*: Increased urinary excretion of magnesium

## **ACTIVITIES**

*alcohol use*: Increased urinary excretion of magnesium

## **Adverse Reactions**

**CNS**: Confusion, decreased reflexes, dizziness, syncope

**CV**: **Arrhythmias, hypotension**

**GI**: Flatulence, vomiting

**MS**: Muscle cramps

**RESP**: Dyspnea, **respiratory depression or paralysis**

**SKIN**: Diaphoresis

**Other**: **Hypermagnesemia, hypersensitivity reactions**, injection-site pain or irritation (I.M. form), laxative dependence, **magnesium toxicity**

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm for some forms of magnesium.
- Magnesium sulfate may cause fetal harm if administered continuously beyond 5 to 7 days to pregnant women causing hypocalcemia and bone abnormalities in the developing fetus.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Some authorities recommend magnesium chloride and magnesium sulfate not be administered within 2 hours prior to delivery because of the risk of hypermagnesemia stimulated respiratory depression in the neonate.
- If magnesium sulfate is administered by continuous IV infusion, especially for more than 24 hours preceding delivery, to control seizures in a toxemic woman, monitor newborn for signs of magnesium toxicity, including neuromuscular or respiratory depression.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that magnesium sulfate is the elemental form of magnesium. Oral preparations aren't all equivalent.
- Be aware that drug isn't metabolized. Drug remaining in the GI tract produces watery stool within 30 minutes to 3 hours.
- Make sure patient chews chewable tablets thoroughly before swallowing.
- Avoid giving other oral drugs within 2 hours of magnesium-containing antacid.
- Before giving drug as laxative, shake oral solution, liquid, or liquid concentrate well and give with a large amount of water.

**WARNING** Observe for and report early evidence of hypermagnesemia: bradycardia, depressed deep tendon reflexes, diplopia, dyspnea, flushing, hypotension, nausea, slurred speech, vomiting, and weakness.

**WARNING** Be aware that magnesium may precipitate myasthenic crisis by decreasing patient's sensitivity to acetylcholine.

- Frequently assess cardiac status of patient taking drugs that lower heart rate, such as beta blockers because magnesium may aggravate symptoms of heart block.

**WARNING** Be aware that magnesium chloride for injection contains the preservative benzyl alcohol, which may cause fatal toxic syndrome in neonates and premature infants.

- Provide adequate diet, exercise, and fluids for patient being treated for constipation.
- Monitor serum electrolyte levels in patients with renal insufficiency because they're at risk for magnesium toxicity.
- Be aware that magnesium salts aren't intended for long-term use. For example, magnesium sulfate may cause fetal abnormalities if administered for more than 5 to 7 days to pregnant women. When magnesium sulfate is administered by continuous I.V. infusion (especially for more than 24 hours preceding delivery) to control convulsions in a toxemic woman, monitor newborn for signs of magnesium toxicity, such as neuromuscular or respiratory depression.

## **PATIENT TEACHING**

- Advise patient to chew magnesium chewable tablets thoroughly before swallowing, and then drink a full glass of water. Mention that tablets have a chalky taste.
- Instruct patient to take magnesium-containing antacid between meals and at bedtime. Urge him not to take other drugs within 2 hours of the antacid.
- Tell patient to notify prescriber and avoid using magnesium-containing laxative if he has abdominal pain, nausea, or vomiting.
- Instruct patient to refrigerate magnesium citrate solution.
- Caution patient about risk of dependence with long-term laxative use.

- Teach patient to prevent constipation by increasing dietary fiber and fluid intake and exercising regularly.
- Inform patient that magnesium supplements used to replace electrolytes can cause diarrhea.

## mannitol

### Osmitrol, Resectisol

## Class and Category

*Pharmacologic class:* Osmotic diuretic

*Therapeutic class:* Diuretic

## Indications and Dosages

➤ *To reduce intracranial or intraocular pressure*

### I.V. INFUSION (OSMITROL)

**Adults and adolescents.** 0.25 g/kg infused over 30 min and repeated every 6 to 8 hrs. If used to reduce intraocular pressure, 1.5 to 2 g/kg of a 15% or 20% solution infused as a single dose over at least 30 min. If used before eye surgery, infused 60 to 90 min before procedure.

### I.V. INFUSION (RESECTISOL)

**Adults and adolescents.** 0.25 to 2 g/kg as 20% solution given over 30 to 60 min and repeated every 6 to 8 hr. If used before eye surgery, 60 to 90 min before procedure.

**Children:** 1 to 2 g/kg or 30 to 60g/m<sup>2</sup> body surface infused over 30 to 60 min. If used before eye surgery, 1.5 to 2 g/kg 60 to 90 min before procedure.

**DOSAGE ADJUSTMENT** For small or debilitated patients, dosage reduced to 0.5 g/kg.

➤ *To measure glomerular filtration rate*

## I.V. INFUSION

**Adults.** 100 ml of a 20% solution (20 g) diluted with 180 ml of sodium chloride injection and infused at a rate of 20 ml/min.

➤ *To provide irrigation during transurethral resection of prostate gland*

## IRRIGATION SOLUTION

**Adults.** 2.5% or 5% solution, as needed.

Route	Onset	Peak	Duration
I.V.*	1-3 hr	Unknown	Up to 8 hr
I.V.†	30-60 min	Unknown	4-8 hr
I.V.‡	In 15 min	Unknown	3-8 hr

\* To produce diuresis.

† To decrease intraocular pressure.

‡ To decrease intracranial pressure.

## Mechanism of Action

Elevates plasma osmolality, causing water to flow from tissues, such as brain and eyes, and from CSF, into extracellular fluid, thereby decreasing intracranial and intraocular pressure.

As an osmotic diuretic, mannitol increases the osmolarity of glomerular filtrate, which decreases water reabsorption. This leads to increased excretion of chloride, sodium, water, and toxic substances.

As an irrigant, mannitol minimizes the hemolytic effects of water used as an irrigant and reduces the movement of hemolyzed blood from the urethra to the systemic circulation, which prevents hemoglobinemia and serious renal complications.

## Incompatibilities

Don't administer mannitol through same I.V. line as blood or blood products.

## Contraindications

Active intracranial bleeding (except during craniotomy), anuria, hypersensitivity to mannitol or its components, severe pulmonary vascular congestion or pulmonary edema, severe hypovolemia

## Interactions

### DRUGS

*digoxin, drugs that prolong the QT interval, neuromuscular blocking agents:* Increased risk of electrolyte imbalances resulting in serious cardiac adverse reactions; increased risk of digitalis toxicity from hypokalemia

*diuretics; nephrotoxic drugs such as aminoglycosides, cyclosporine:* Increased risk of renal failure and toxicity  
*lithium:* Initial increased elimination of lithium followed by increased risk of lithium toxicity in patients with hypovolemia or renal impairment

*neurotoxic drugs such as aminoglycosides:* Increased risk of CNS toxicity

*renally eliminated drugs:* Increased elimination and decreased effectiveness of these drugs

## Adverse Reactions

**CNS:** Asthenia, chills, **coma**, confusion, dizziness, fever, headache, lethargy, malaise, **rebound increased intracranial pressure, seizures**

**CV:** Chest pain, **heart failure**, hypertension, **hypotension**, palpitations, peripheral edema, tachycardia, thrombophlebitis

**EENT:** Blurred vision, dry mouth, rhinitis

**GI:** Diarrhea, nausea, vomiting

**GU:** **Acute kidney injury, anuria, azotemia**, hematuria, oliguria, osmotic nephrosis, polyuria, urine retention

**MS:** Musculoskeletal stiffness, myalgia

**RESP:** Cough, dyspnea, **pulmonary edema**

**SKIN:** Diaphoresis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, dehydration, extravasation (with compartment syndrome, swelling, and tissue necrosis), generalized discomfort or pain, **hyperkalemia, hypernatremia, hyperosmolarity**, hypervolemia, **hypokalemia, hyponatremia** (dilutional), hypovolemia, infusion-site reactions (erythema, inflammation, pain, phlebitis, pruritus, or extravasation complications of compartment syndrome, tissue necrosis), **metabolic acidosis**, thirst

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that if crystals form in mannitol solution exposed to low temperature, solution should be placed in hot-water bath to redissolve crystals.
- Know that elderly patients and patients with preexisting renal disease are at greater risk for developing adverse reactions. Expect to evaluate patient's cardiac, pulmonary, and renal status and correct any preexisting fluid and electrolyte imbalances before therapy begins, as ordered.
- Use a 5-micron in-line filter when administering drug solution of 15% or greater. Know that infusion of hypertonic solutions of mannitol should be administered through a large central vein, if possible, because administration through a peripheral vein can cause severe infusion-site reactions, such as compartment syndrome and swelling associated with extravasation.
- Be aware that depending on dosage and duration of mannitol administration, acid-base and electrolyte imbalances may occur, which can be severe and potentially fatal. Monitor central venous pressure, fluid intake and output, and vital signs every hour during I.V. infusion of mannitol. Measure urine output with indwelling urinary catheter, as appropriate. Notify prescriber if renal function worsens and expect mannitol to be discontinued.

**WARNING** Assess patient for hypersensitivity reactions, including anaphylaxis, dyspnea, and hypotension; cardiac arrest and death have occurred. If hypersensitivity reactions present, stop infusion immediately, notify prescriber, and expect to provide supportive emergency care. Be aware that concomitant

administration of nephrotoxic drugs or other diuretics should be avoided during mannitol therapy.

- Check weight and monitor BUN and serum creatinine electrolyte levels daily, as ordered.
- Expect to monitor patient's cardiac, pulmonary, and renal function as well as signs and symptoms of hyper- or hypovolemia for patient receiving mannitol therapy for reduction in intracranial pressure. Also expect to monitor this patient's acid-base balance, intracranial pressure, osmol gap, and serum electrolytes and osmolarity.

**WARNING** Monitor patient, especially patient with impaired renal function, for CNS toxicity such as coma, confusion, or lethargy. This may occur as a result of high serum mannitol concentrations or disturbances of electrolyte and acid-base balance caused by mannitol administration. Patients with preexisting compromise of the blood-brain barrier are at increased risk for increasing cerebral edema with mannitol use. Monitor patient closely for a rebound increase in intracranial pressure for at least several hours after mannitol has been discontinued. Know that use of neurotoxic drugs should be avoided, if possible, during mannitol administration.

- Provide frequent mouth care to relieve dry mouth and thirst.
- Know that high concentrations of mannitol may produce false low results for inorganic phosphorus blood concentrations. Mannitol therapy may also produce false positive results in tests for blood ethylene glycol concentrations.

## **PATIENT TEACHING**

- Inform patient that he may experience dry mouth and thirst during mannitol therapy.
- Instruct patient to report chest pain, difficulty breathing, or pain at I.V. site, along with any other new, persistent, or severe adverse reactions.

# maraviroc

## Selzentry

### Class and Category

*Pharmacologic class:* CCR5 co-receptor antagonist

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat CCR5-tropic human immunodeficiency virus type 1 (HIV-1) infection*

#### ORAL SOLUTION, TABLETS

**Adults taking potent CYP3A inhibitors such as boceprevir, delavirdine, clarithromycin, elvitegravir/ritonavir, itraconazole, ketoconazole, nefazodone, protease inhibitors except tipranavir/ritonavir, or telithromycin; children age 2 and over weighing 40 kg (88 lb) or more.** 150 mg twice daily.

**Children age 2 and overweighing at least 30 kg (66 kg) to less than 40 kg (88 lb) taking potent CYP3A inhibitors such as boceprevir, delavirdine, clarithromycin, elvitegravir/ritonavir, itraconazole, ketoconazole, nefazodone, protease inhibitors except tipranavir/ritonavir, or telithromycin.** 100 mg twice daily.

**Children age 2 and overweighing at least 20 kg (44 lb) to less than 30 kg (66 lb) taking potent CYP3A**

**inhibitors such as boceprevir, delavirdine, clarithromycin, elvitegravir/ritonavir, itraconazole, ketoconazole, nefazodone, protease inhibitors except tipranavir/ritonavir, or telithromycin. 75 mg (tablet) or 80 mg (oral solution) twice daily.**

**Children age 2 and overweighing at least 10 kg (22 lb) to less than 20 kg (44 lb) taking potent CYP3A inhibitors such as boceprevir, delavirdine, clarithromycin, elvitegravir/ritonavir, itraconazole, ketoconazole, nefazodone, protease inhibitors except tipranavir/ritonavir, or telithromycin. 50 mg twice daily.**

**Adults taking potent CYP3A inducers (without a potent CYP3A inhibitor) such as carbamazepine, efavirenz, etravirine, phenobarbital, phenytoin, or rifampin. 600 mg twice daily.**

**Adults and children age 2 and over weighing at least 30 kg (66 lb) taking drugs that are not potent CYP3A inducers or inhibitors. 300 mg twice daily.**

## **Mechanism of Action**

Selectively binds to the human chemokine receptor CCR5 present on the cell membrane, preventing an interaction that would allow CCR5-tropic HIV-1 to enter the cell. This prevents replication of the CCR5-tropic human immunodeficiency virus type I.

## **Contraindications**

End-stage renal disease or severe renal impairment in patients receiving potent CYP3A inducers or inhibitors, hypersensitivity to maraviroc or its components

# Interactions

## DRUGS

*CYP3A and P-gp inducers:* Decreased effectiveness of maraviroc

*CYP3A and P-gp inhibitors:* Increased plasma concentration of maraviroc with increased risk of adverse reactions

*multidrug resistance-associated protein (MRP)2 and organic anion transporting polypeptide (OATP)1B1 inducers:* Possibly decreased effectiveness of maraviroc

*multidrug resistance-associated protein (MRP)2 and organic anion transporting polypeptide (OATP)1B1 inhibitors:* Possibly increased plasma concentration of maraviroc with increased risk of adverse reactions

*St. John's wort:* Decreased plasma concentration of maraviroc with substantially decreased effectiveness; increased risk of development of resistance to maraviroc

## Adverse Reactions

**CNS:** Anxiety, changes in levels of consciousness including loss of consciousness, **CVA**, depression, dizziness, dysesthesias, facial palsy, fever, malaise, memory loss excluding dementia, paresthesias, peripheral neuropathies, sensory abnormalities, sleep disturbances, **seizures**, syncope, tremor

**CV:** **Acute heart failure**, coronary artery disease, **coronary artery occlusion**, **endocarditis**, hypertension, **MI**, myocardial ischemia, orthostatic hypotension, **unstable angina**

**EENT:** Conjunctivitis, ear disorders, hemianopia, nasal or ocular infections or inflammations, oral lesions, paranasal sinus disorders, visual field defects

**GI:** Abdominal distention, appetite disorders, bilirubin increase, bloating, cholestatic jaundice, constipation, elevated pancreatic and liver enzymes, flatulence, gastrointestinal atonic and hypomotility disorders, **hepatic cirrhosis or failure, hepatitis, hepatotoxicity, jaundice, portal vein thrombosis**

**GU:** Ejaculation and erection disorders, urinary tract signs and symptoms

**HEME:** Anemias, eosinophilia, **hypoplastic anemia, marrow depression, neutropenia**

**MS:** Elevated creatine kinase, joint or muscle aches or pains, myositis, osteonecrosis, **rhabdomyolysis**

**RESP:** **Breathing difficulties**, cough, respiratory infections

**SKIN:** Acne, alopecia, apocrine and eccrine gland disorders, benign skin neoplasms, blisters, erythemas, lipodystrophies, nail and nail bed disorders, pruritus, rash (could be severe), **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Angioedema; drug reaction with eosinophilia and systemic symptoms (DRESS)**; elevated IgE; generalized discomfort or pain; immune reconstitution syndrome; infections such as bacterial, herpes, *Neisseria*, respiratory, tinea, and viral

## Childbearing Considerations

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Know that maraviroc is not recommended in patients with dual/mixed- or CXCR4-tropic HIV-1 infections.
- Be sure patient has been checked for CCR5 tropism before treatment with maraviroc is started, because it is only effective against this type of infection.

**WARNING** Check patient's bilirubin and liver enzyme levels before maraviroc treatment is started and periodically throughout treatment, as ordered, because drug increases risk of hepatotoxicity. Know that patients with a history of liver dysfunction or patients with co-infection with hepatitis B and/or C virus may require additional monitoring. Severe rash or evidence of systemic allergic reactions (including DRESS, eosinophilia, elevated IgE, and other systemic symptoms) has occurred with hepatotoxicity about 1 month after maraviroc therapy was started in some patients. Know that cases of hepatitis have occurred in some patients in the absence of allergic manifestations or who have had no history of hepatic disease.

**WARNING** Monitor patient closely for severe skin reactions. Notify prescriber and expect maraviroc to be discontinued immediately if patient develops a rash that is accompanied by blisters, conjunctivitis, eosinophilia, facial edema, fever, joint or muscle aches, lip swelling, malaise, or oral lesions. Be aware that a delay in discontinuing the drug may result in a life-threatening situation.

- Monitor patient's cardiovascular status throughout maraviroc therapy because, although uncommon, major events such as acute heart failure, endocarditis, hypertension, myocardial infarction or ischemia and unstable angina have been reported with maraviroc therapy. Pay close attention to the patient's blood pressure if renal impairment is present, because of risk of orthostatic hypotension. Patients with severe renal impairment or end-stage renal disease experiencing orthostatic hypotension should be evaluated for a dosage reduction.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including maraviroc. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.
- Assess patient frequently for signs and symptoms of infection, because maraviroc affects some immune cells placing patient at increased risk.
- Be aware that maraviroc may put patient at increased risk for malignant tumors because of its effect on the immune system.

## PATIENT TEACHING

- Advise patient to avoid missing doses of maraviroc, as it can result in the development of resistance to drug. If she misses a dose, she should take it as soon as she remembers, but should not double the next dose or take more than prescribed.

**WARNING** Inform patient to seek immediate medical attention if signs and symptoms of hepatitis or an allergic reaction occurs.

- Advise patients with a history of cardiovascular disease or postural hypotension to notify prescriber if signs and symptoms develop or increase, as such patients are at increased risk for cardiovascular events.
- Tell patient to avoid hazardous activities, such as driving, until drug's CNS effects are known. Urge her to take safety precautions to prevent falling if she has adverse reactions, such as dizziness.
- Instruct patient to alert all prescribers of maraviroc therapy and not to take any over-the-counter medication, including herbal products, without

the consent of the prescriber. Inform her that St. John's wort should not be taken while on maraviroc therapy.

- Advise female patient to alert prescriber if pregnancy is suspected or has occurred, and encourage her to register with the Antiretroviral Pregnancy Registry by calling 1-800-258-4263.
- Inform mothers that breastfeeding is not recommended during maraviroc therapy.
- Instruct patient prescribed oral solution to throw away any unused solution 60 days after first opening the bottle.

## meloxicam

**Mobic, Vivlodex**

### Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic

### Indications and Dosages

➤ *To relieve signs and symptoms of osteoarthritis*

#### **ORAL SUSPENSION, TABLETS (MOBIC)**

**Adults.** 7.5 mg daily. *Maximum:* 15 mg daily.

#### **CAPSULES (VIVLODEX)**

**Adults.** 5 mg once daily. *Maximum:* 10 mg once daily (5 mg once daily for patient on hemodialysis).

➤ *To relieve signs and symptoms of rheumatoid arthritis*

## **ORAL SUSPENSION, TABLETS (MOBIC)**

**Adults.** 7.5 mg daily. *Maximum:* 15 mg daily.

- *To relieve pauciarticular or polyarticular signs and symptoms of juvenile rheumatoid arthritis*

## **ORAL SUSPENSION, TABLETS (MOBIC)**

**Children age 2 and over.** 0.125 mg/kg daily. *Maximum:* 7.5 mg daily.

***DOSAGE ADJUSTMENT*** For patient on hemodialysis, the maximum dosage of Mobic brand not to exceed 7.5 mg daily and for Vivlodex brand not to exceed 5 mg daily.

## **Mechanism of Action**

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local pain, swelling, and vasodilation. By inhibiting prostaglandins, the NSAID meloxicam reduces inflammatory symptoms. It also relieves pain because prostaglandins promote pain transmission from the periphery to the spinal cord.

## **Contraindications**

History of angioedema, asthma, bronchospasm, nasal polyps, rhinitis, or urticaria induced by hypersensitivity to aspirin or other NSAIDs; hypersensitivity to meloxicam or its components; setting of coronary artery bypass graft (CABG) surgery

## **Interactions**

### **DRUGS**

*ACE inhibitors, angiotensin receptor blockers, beta-blockers*: Decreased antihypertensive effect, increased risk of renal failure in patients who are elderly, volume-depleted, or have existing renal impairment

*anticoagulants (warfarin), antiplatelets (aspirin), selective serotonin reuptake inhibitors (SSRIs), serotonin norepinephrine reuptake inhibitors (SNRIs)*: Synergistic effect on bleeding.

*aspirin*: Increased risk of GI adverse reactions such as bleeding and ulceration

*cyclosporine*: Increased risk of nephrotoxicity

*diuretics (loop and thiazide)*: Decreased diuretic effect; possibly renal impairment

*lithium*: Elevated blood lithium level, possibly lithium toxicity

*methotrexate*: Increased risk of methotrexate toxicity

*NSAIDs, salicylates*: Increased risk of GI toxicity

*pemetrexed*: Increased risk of GI toxicity, myelosuppression, and renal toxicity

## ACTIVITIES

*alcohol use, smoking*: Increased risk of GI bleeding

## Adverse Reactions

**CNS**: Confusion, **CVA**, dizziness, fever, headache, insomnia, mood alteration, **seizures**

**CV**: Chest pain, edema, **heart failure**, hypertension, **MI**, tachycardia, vasculitis

**EENT**: Laryngitis, pharyngitis, sinusitis

**GI**: Abdominal pain, anorexia, colitis, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, elevated liver enzymes, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, **GI bleeding** and

ulceration, **hepatic failure**, **hepatitis**, indigestion, **melena**, nausea, **pancreatitis**, **perforation of intestines or stomach**, stomatitis, vomiting

**GU: Acute renal failure**, acute urine retention (children), urinary frequency, UTI

**HEME: Agranulocytosis**, anemia, easy bruising, **hemolytic anemia**, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS: Arthralgia**; back pain; joint crepitation, effusion, or swelling; muscle spasms; myalgia

**RESP: Asthma**, **bronchospasm**, cough, dyspnea, **respiratory depression**, upper respiratory tract infection

**SKIN: Erythema multiforme**, **exfoliative dermatitis**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other: Anaphylaxis**, **angioedema**, flu-like symptoms

## Childbearing Considerations

### PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

### REPRODUCTION

- Be aware that drug may delay or prevent rupture of ovarian follicles, which has been associated with reversible infertility in some women.
- Drug is not recommended for use in women having difficulty conceiving or who are undergoing investigation of infertility.

## Nursing Considerations

- Be aware that NSAIDs like meloxicam should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Know that the risk of heart failure increases with NSAID use. Meloxicam should not be used in patients with severe heart failure but, if unavoidable, monitor patient for worsening of heart failure.
- Use meloxicam with extreme caution in patients with history of GI bleeding or ulcer disease because NSAIDs, such as meloxicam, increase risk of GI bleeding and ulceration. Expect to use drug for shortest time possible in these patients.
- Be aware that capsules are not interchangeable with other formulations of oral meloxicam even if the total milligram strength is the same. Do not substitute similar dose strengths of other meloxicam products for capsule form.
- Be aware that serious GI tract bleeding, perforation, and ulceration may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food and a full glass of water. If GI distress occurs, withhold drug and notify prescriber immediately.
- Use meloxicam cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk. These events may occur early in treatment and risk increases with duration of use. Be aware that these events have occurred even in patients who do not have a history or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, slurring of speech, shortness of breath, or weakness. If

any signs and symptoms develop, withhold meloxicam, alert prescriber immediately, and provide supportive care, as prescribed.

- Monitor patient—especially if elderly or taking meloxicam long-term—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes because, rarely, elevations may progress to severe hepatic reactions, including fatal hepatitis, hepatic failure, or liver necrosis.
- Monitor BUN and serum creatinine levels in elderly patients; patients taking ACE inhibitors, angiotensin II receptor antagonists, or diuretics; and patients with heart failure, hepatic dysfunction, or impaired renal function. Drug may cause renal failure.
- Monitor CBC for decreased hemoglobin and hematocrit. Drug may worsen anemia.

**WARNING** Keep in mind if patient has bone marrow suppression or is receiving an antineoplastic drug, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of meloxicam may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for rash or other hypersensitivity reaction because meloxicam is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Monitor patient for adequate hydration before beginning meloxicam therapy to decrease risk of renal dysfunction.

## **PATIENT TEACHING**

- Instruct patient to take meloxicam with food or after meals if she has stomach upset.

- For oral suspension, tell patient to shake container gently before use.
- Caution patient to avoid using other NSAIDs, aspirin, or products containing aspirin while taking meloxicam.
- Advise patient to refrain from alcohol use or smoking because these activities may increase risk of adverse GI reactions.
- Instruct patient to notify prescriber if she develops signs or symptoms of hepatic dysfunction, such as dark yellow or brown urine, fatigue, fever, itching, lethargy, nausea, or yellowing of eyes or skin.
- Advise patient, especially if she's taking an oral anticoagulant such as warfarin, to report immediately signs of bleeding, such as black or tarry stools, blood in urine, easy bruising, or stomach pain.
- Alert women of childbearing age that meloxicam may cause a reversible delay in ovulation that may make conception more difficult. If pregnancy is desired, she should consult with prescriber about discontinuing meloxicam therapy and using an alternative drug to treat her condition.
- Caution pregnant patient not to take NSAIDs, such as meloxicam, during the last trimester because they may cause premature closure of ductus arteriosus.
- Explain that meloxicam may increase risk of serious adverse cardiovascular reactions including heart failure; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, edema, shortness of breath, slurring of speech, unexplained weight gain, or weakness.
- Explain that meloxicam may increase risk of serious adverse GI reactions; emphasize importance of seeking immediate medical attention for such signs and symptoms as abdominal or epigastric pain, black or tarry stools, indigestion, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge her to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.

## memantine hydrochloride

**Namenda, Namenda XR**

# Class and Category

*Pharmacologic class:* N-methyl-D-aspartate (NMDA) receptor antagonist

*Therapeutic class:* Antidementia agent

# Indications and Dosages

- *To treat moderate-to-severe dementia of the Alzheimer's type*

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 5 mg daily, increased by 5 mg/wk, as needed, to 10 mg daily in two divided doses; then 15 mg daily with one 5-mg and one 10-mg dose daily; then 20 mg daily in two divided doses. *Maintenance:* 20 mg daily.

## E.R. CAPSULES

**Adults.** *Initial:* 7 mg once daily, increased by 7 mg/wk, as needed, to 28 mg once daily. *Maximum:* 28 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment, maintenance dosage reduced to 5 mg twice daily for oral solution and tablet form and 14 mg once daily for extended-release capsules.

# Contraindications

Hypersensitivity to memantine, amantadine, or their components

# Interactions

## DRUGS

*amantadine, dextromethorphan, ketamine*: Possibly additive effects

*carbonic anhydrase inhibitors, sodium bicarbonate*: Decreased memantine clearance, leading to increased blood drug levels and risk of adverse effects

## Adverse Reactions

**CNS:** Abnormal gait, agitation, akathisia, anxiety, confusion, **CVA**, delirium, delusions, depression, dizziness, drowsiness, dyskinesia, fatigue, hallucinations, headache, hyperexcitability, insomnia, **neuroleptic malignant syndrome**, psychosis, restlessness, **seizures**, somnolence, **suicidal ideation**, tardive dyskinesia

**CV:** **AV block**, chest pain, **congestive heart failure**, hypertension, peripheral edema, **prolonged QT interval**, **supraventricular tachycardia**, tachycardia

**ENDO:** **Hypoglycemia**

**GI:** **Acute pancreatitis**, anorexia, colitis, constipation, diarrhea, **hepatic failure**, **hepatitis**, ileus, nausea, **pancreatitis**, vomiting

**GU:** **Acute renal failure**, elevated creatinine levels, impotence, **renal insufficiency**, urinary incontinence, UTI

**HEME:** **Agranulocytosis**, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**, **thrombotic thrombocytopenic purpura**

**MS:** Arthralgia, back pain

## Mechanism of Action

Memantine blocks the excitatory amino acid glutamate on N-methyl-D-aspartate (NMDA) receptor cells in the CNS. In Alzheimer's disease, glutamate levels are abnormally high when brain cells are both active and at rest. Normally, when certain brain cells are resting, magnesium ions block NMDA receptors and prevent influx of calcium and sodium ions and outflow of potassium ions. When learning and memory cells in the brain are active, glutamate engages with NMDA receptors, magnesium ions are removed from NMDA receptors, and cells are depolarized. During depolarization, calcium and sodium ions enter brain cells, and potassium ions leave. In Alzheimer's disease, excessive circulating glutamate permanently removes magnesium ions and opens ion channels. Excessive influx of calcium may damage brain cells and play a major role in Alzheimer's disease. What's more, dying brain cells release additional glutamate, worsening the cycle of brain cell destruction.

Memantine replaces magnesium on NMDA receptors of brain cells, closing ion channels and preventing calcium influx and the resulting damage to brain cells. By preventing excessive brain cell death, memantine slows progression of Alzheimer's disease.

## Description

**RESP:** Bronchitis, cough, dyspnea, upper respiratory tract infection

**SKIN:** **Stevens-Johnson syndrome**

**Other:** Generalized pain, flu-like symptoms

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use memantine cautiously in patients with renal tubular acidosis or severe UTI because these conditions make urine alkaline, reducing memantine excretion and increasing the risk of adverse reactions.
- Use cautiously in patients with severe hepatic impairment because drug undergoes partial hepatic metabolism, which may increase risk of adverse reactions.
- Monitor patient's response to memantine, and notify prescriber if bothersome or serious adverse reactions occur.
- Monitor patient closely for suicidal thoughts.

## PATIENT TEACHING

- Instruct patient to take memantine exactly as prescribed. Inform him to notify the prescriber if he fails to take the drug for several days, as dosage adjustments may be necessary. Caution him not to double dose if he misses a single dose. Instead, tell him to take the next dose as scheduled.
- Advise patient to avoid a diet excessively high in fruits and vegetables because these foods contribute to alkaline urine, which can alter memantine clearance and increase adverse reactions.
- Tell patient that capsule should be swallowed whole and not chewed, crushed, or opened. If patient has difficulty swallowing the capsule, instruct him to open capsule, sprinkle contents on applesauce, and immediately consume entire amount of applesauce.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Alert patient or caregiver that memantine has the potential to cause suicidal thoughts. If present, prescriber should be notified immediately.

**meperidine hydrochloride**

**(pethidine hydrochloride)**

**Demerol**

## Class, Category, and Schedule

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

## Indications and Dosages

- *To relieve pain severe enough to require opioid treatment and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated*

## **SYRUP, TABLETS, I.M. OR SUBCUTANEOUS INJECTION**

**Adults.** 50 to 150 mg every 3 to 4 hr, as needed.

**Children.** 1.1 to 1.8 mg/kg (0.5 to 0.8 mg/lb) every 3 to 4 hr, as needed.

## **I.V. INFUSION, I.V. INJECTION**

**Adults.** 15 to 35 mg/hr, as needed. Alternatively, dosage highly individualized using patient-controlled analgesia device.

- *To provide preoperative sedation*

## **I.M. OR SUBCUTANEOUS INJECTION**

**Adults.** 50 to 100 mg 30 to 90 min before surgery.

**Children.** 1 to 2 mg/kg (0.5 to 1 mg/lb) 30 to 90 min before surgery.

- *As adjunct to anesthesia*

## **I.V. INFUSION OR INJECTION**

**Adults.** Individualized. Repeated slow injections of 10 mg/ml solution or continuous infusion of dilute solution (1 mg/ml) titrated as needed.

- *To provide obstetric analgesia*

## **I.M. OR SUBCUTANEOUS INJECTION**

**Adults.** 50 to 100 mg given with regular, painful contractions; repeated every 1 to 3 hr.

**DOSAGE ADJUSTMENT** For elderly patients, total daily dosage decreased. For patients receiving CNS depressants, phenothiazines, and tranquilizers concurrently, dosage proportionately reduced by 25% to 50%.

Route	Onset	Peak	Duration
P.O.	15 min	1-1.5 hr	2-4 hr
I.V.	1 min	5-7 min	2-4 hr
I.M., SubQ	10-15 min	30-50 min	2-4 hr

## Mechanism of Action

Binds with opiate receptors in the spinal cord and higher levels of the CNS. In this way, meperidine stimulates kappa and mu receptors, which alters the perception of and emotional response to pain.

## Incompatibilities

Don't mix meperidine in same syringe with aminophylline, barbiturates, heparin, iodides, methicillin, morphine sulfate, phenytoin, sodium bicarbonate, sulfadiazine, or sulfoxazole.

## Contraindications

Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment; hypersensitivity to meperidone or its components; known or suspected gastrointestinal obstruction, including paralytic ileus; significant respiratory depression; use within 14 days of MAO inhibitor therapy

## Interactions

## DRUGS

*5-HT<sub>3</sub> receptor antagonists, drugs that affect the serotonin neurotransmitter system (mirtazapine, tramadol, trazodone), MAO inhibitors including I.V. methylene blue and linezolid, selected muscle relaxants (cyclobenzaprine, metaxalone), selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors (SNRIs), tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

*acyclovir:* Possibly increased blood meperidine level

*anticholinergics:* Increased risk of severe constipation which may lead to paralytic ileus; increased risk of urinary retention

*benzodiazepines, CNS depressants, other opioids, sedating antihistamines, tricyclic antidepressants:* Increased risk of significant respiratory depression and other life-threatening adverse effects

*cimetidine:* Reduced clearance and volume of distribution of meperidine

*CYP3A4 inducers such as carbamazepine, phenytoin,*

*rifampin:* Increased clearance of meperidine with decreased effectiveness

*CYP3A4 inhibitors such as azole-antifungals, macrolide antibiotics, protease inhibitors:* Decreased clearance of meperidine resulting in increased or prolonged opioid effects

*diuretics:* Reduced effectiveness of diuretics

*mixed agonist/antagonist and partial agonist opioid*

*analgesics such as buprenorphine, butorphanol,*

*nalbuphine, pentazocine:* Decreased analgesic effect of meperidine; possibly precipitation of withdrawal symptoms

*MAO inhibitors:* Increased risk of coma, hypotension, or severe respiratory depression

*muscle relaxants:* Possibly enhanced neuromuscular blocking action of skeletal muscle relaxants; increased degree of respiratory depression

## **ACTIVITIES**

*alcohol use:* Possibly increased CNS and respiratory depression and hypotension

## **Adverse Reactions**

**CNS:** Agitation, confusion, delirium, depression, dizziness, drowsiness, headache, **increased intracranial pressure**, lack of coordination, malaise, mood changes, nervousness, nightmares, restlessness, **seizures**, syncope, transient hallucinations or disorientation, tremor, weakness

**CV:** **Hypotension**, orthostatic hypotension, tachycardia

**EENT:** Blurred vision, diplopia, dry mouth

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal cramps or pain, anorexia, constipation, ileus, nausea, vomiting

**GU:** Decreased libido, dysuria, erectile dysfunction, impotence, infertility, lack of menstruation, urinary frequency, urine retention

**MS:** Involuntary muscle movements

**RESP:** Dyspnea, **respiratory arrest or depression**, wheezing

**SKIN:** Diaphoresis, flushing, pruritus, rash, urticaria

**Other:** **Anaphylaxis**; injection-site pain, redness, or swelling; physical and psychological dependence

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the newborn. Monitor newborn closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, monitor infant for excess sedation and respiratory depression and for withdrawal symptoms when breastfeeding is stopped.

## **REPRODUCTION**

- Chronic use of opioids may reduce fertility.

## **Nursing Considerations**

- Be aware that excessive use of opioids like meperidine may lead to abuse, addiction, misuse, overdose, and possibly death. Because of this, a Risk Evaluation and Mitigation Strategy (REMS) is required. Monitor patient's intake of drug closely and for evidence of physical dependence.

- Know that chronic maternal use of meperidine during pregnancy can result in neonatal opioid withdrawal syndrome (NOWS), which may be life-threatening if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to opioid drugs like meperidine for a prolonged period while in utero.
- Use meperidine with extreme caution in patients with acute abdominal conditions, hepatic or renal disorders, hypothyroidism, prostatic hyperplasia, seizures, or supraventricular tachycardia.
- Use cautiously in debilitated patients or patients with adrenocortical insufficiency, pheochromocytoma, sickle cell anemia, toxic psychosis, and any other condition that might worsen with CNS depression, such as acute alcoholism.
- Be aware that meperidine should only be used concomitantly with benzodiazepine and other CNS depressants therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of meperidine to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.
- Be aware that dosing errors related to confusion between milligrams (mg) and milliliters (ml) and different concentrations of oral solutions can result in accidental overdose and death. Check dosage and concentration of oral solution very carefully before administering.
- Dilute meperidine syrup with water before use to minimize local anesthetic effect.
- Give I.V. dose slowly by direct injection or as a slow continuous infusion. Mix with D<sub>5</sub>W, normal saline solution, or Ringer's or lactated Ringer's solution.
- Keep naloxone available when giving I.V. meperidine.
- Be aware that subcutaneous injection is painful and isn't recommended unless no other route can be used.
- Be aware that oral form of meperidine is less than half as effective as parenteral meperidine. Give I.M. form when possible, and expect to increase dosage when switching patient to oral form.

**WARNING** Monitor patient's respiratory and cardiovascular status during treatment. Notify prescriber immediately and expect to discontinue drug if respiratory rate falls

to less than 12 breaths/minute or if respiratory depth decreases because serious, life-threatening, or fatal respiratory depression may occur. Monitor patient especially during initiation or following a dose increase.

- Monitor patient's bowel function to detect constipation, and assess the need for stool softeners.
- Know that prolonged use may increase risk of toxicity exhibited by seizures from the accumulation of the meperidine metabolite, normeperidine.
- Expect withdrawal symptoms to occur if drug is abruptly withdrawn after long-term use.
- Be aware that concomitant use with CYP3A4 inhibitors or discontinuation of CYP3A4 inducers can result in fatal overdose of meperidine.

**WARNING** Know that many drugs may interact with opioids like meperidine to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If confirmed, expect to administer corticosteroids and wean patient off meperidine, if possible.

## **PATIENT TEACHING**

- Inform patient that meperidine is a controlled substance.
- Instruct patient to use only a calibrated measuring device when measuring a dose of oral solution and never use a teaspoon or tablespoon,

because a spoon is inexact and it is easy to use the wrong size spoon when measuring. Advise patient to dilute oral solution in half a glass of water before taking, because the undiluted solution may exert a slight topical anesthetic effect on mucous membranes.

- Advise patient to take drug exactly as prescribed. Warn patient that excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death. If patient has been receiving meperidine for more than a few weeks and the drug is to be discontinued, advise patient to taper dosage off, as abrupt discontinuation could precipitate withdrawal symptoms.
- Instruct patient to report constipation, severe nausea, and shortness of breath.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to prevent postoperative atelectasis by turning, coughing, and deep breathing.
- Warn patient not to consume alcohol or take a benzodiazepine without prescriber knowledge, as severe respiratory depression can occur and may lead to death.
- Urge patient to avoid alcohol, sedatives, and tranquilizers during therapy.
- Inform patient that long-term use of opioids like meperidine may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms to prescriber.
- Caution pregnant patient not to increase dosage or take drug for a prolonged period, as adverse effects can cause infant to experience life-threatening withdrawal when born.
- Instruct patient to notify all prescribers of opioid use.
- Stress importance of keeping meperidine out of the reach of children, as ingestion may lead to a fatal overdose.

## meropenem

### **Merrem I.V.**

# Class and Category

*Pharmacologic class:* Carbapenem

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat complicated appendicitis and peritonitis caused by susceptible strains of alpha-hemolytic streptococci, Bacteroides fragilis, B. thetaiotaomicron, Escherichia coli, Klebsiella pneumoniae, Peptostreptococcus species, or Pseudomonas aeruginosa*

### I.V. INFUSION OR INJECTION

**Adults and children weighing more than 50 kg (110 lb).** 1 g every 8 hr infused over 15 to 30 min or given as a bolus over 3 to 5 min.

**Children over age 3 months weighing less than 50 kg (110 lb).** 20 mg/kg every 8 hr infused over 15 to 30 min or given as bolus over 3 to 5 min. *Maximum:* 1 g every 8 hr.

### I.V. INFUSION

**Infants with gestational age of 32 weeks and over and postnatal age of 2 weeks and over.** 30 mg/kg every 8 hr given over 30 min.

**Infants with gestational age of 32 weeks and over but postnatal age less than 2 weeks or infants with gestational age less than 32 weeks but postnatal age of 2 weeks or over.** 20 mg/kg every 8 hr given over 30 min.

**Infants with gestational age less than 32 weeks and postnatal age less than 2 weeks.** 20 mg/kg every 12 hr

given over 30 min.

- *To treat complicated skin and skin structure infections caused by B. fragilis, Enterococcus faecalis (excluding vancomycin-resistant isolates), E. coli, Peptostreptococcus species, Proteus mirabilis, P. aeruginosa, Staphylococcus aureus, Streptococcus agalactiae, S. pyogenes, and viridans group streptococci*

## **I.V. INFUSION OR INJECTION**

**Adults and children weighing more than 50 kg (110 lb).** 500 mg (1 g if caused by *Pseudomonas aeruginosa*) every 8 hr infused over 15 to 30 min or given as a bolus over 3 to 5 min.

**Children over age 3 months weighing 50 kg (110 lb) or less.** 10 mg/kg (20 mg/kg if caused by *Pseudomonas aeruginosa*) every 8 hr infused over 15 to 30 min or given as bolus over 3 to 5 min. *Maximum:* 500 mg every 8 hr.

- *To treat bacterial meningitis caused by Haemophilus influenzae, Neisseria meningitidis, or Streptococcus pneumoniae (penicillin-susceptible isolates) in children*

## **I.V. INFUSION OR INJECTION**

**Children weighing more than 50 kg (110 lb).** 2 g every 8 hr infused over 15 to 30 min or given as a bolus over 3 to 5 min.

**Children over age 3 months weighing less than 50 kg (110 lb).** 40 mg/kg every 8 hr infused over 15 to 30 min or given as bolus over 3 to 5 min. *Maximum:* 2 g every 8 hr.

***DOSAGE ADJUSTMENT*** For adult patients with a creatinine clearance of 26 to 50 ml/min, dosage interval increased to every 12 hours. For adult patients with a creatinine

clearance of 10 to 25 ml/min, dosage reduced by half and given every 12 hr. For adults with creatinine clearance less than 10 ml/min, dosage reduced by half and given every 24 hr. There is no experience for children with renal impairment.

## Mechanism of Action

Penetrates cell walls of most gram-negative and gram-positive bacteria, inactivating penicillin-binding proteins. This action inhibits bacterial cell wall synthesis and causes cell death.

## Incompatibilities

Don't mix meropenem in same solution with other drugs.

## Contraindications

Hypersensitivity to meropenem, other carbapenem drugs, beta-lactams, or their components

## Interactions

### DRUGS

*probenecid*: Inhibited renal excretion of meropenem increasing meropenem plasma concentrations

*valproic acid*: Possibly reduced blood level of valproic acid to subtherapeutic level

## Adverse Reactions

**CNS:** Headache, paresthesias, **seizures**

**CV:** **Shock**

**EENT:** Epistaxis, glossitis, oral candidiasis

**GI:** Anorexia, constipation, diarrhea, elevated liver enzymes, nausea, **pseudomembranous colitis**, vomiting

**GU:** Elevated BUN and serum creatinine levels, hematuria, **renal failure**

**HEME:** **Agranulocytosis**, **hemolytic anemia**, **leukopenia**, **neutropenia**, positive Coombs' test

**RESP:** **Apnea**, dyspnea

**SKIN:** Acute generalized exanthematous pustulosis, diaper rash from candidiasis (children), **erythema multiforme**, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Anaphylaxis**; **angioedema**; **drug reaction with eosinophilia and systemic symptoms (DRESS)**; injection-site inflammation, pain, phlebitis, or thrombophlebitis; **sepsis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Obtain body fluid and tissue samples, as ordered, for culture and sensitivity testing. Expect to review test results, if possible, before giving first dose of meropenem.
- For I.V. bolus, add 10 ml sterile water for injection to 500 mg/20-ml vial, or 20 ml diluent to 1 g/30-ml vial of drug. Shake to dissolve.

**WARNING** Be aware that fatal hypersensitivity reactions have occurred with meropenem use. Determine whether patient has had previous reactions to antibiotics or other allergens. Monitor patient closely and stop drug immediately if signs and symptoms of anaphylaxis occur. Notify prescriber, and expect to provide supportive emergency care that may include airway management, epinephrine and I.V. steroid administration, and oxygen.

- Monitor patient closely for diarrhea, which may indicate pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold meropenem and treat with an antibiotic effective against *C. difficile*, and electrolytes, fluids, and protein.
- Monitor patient for blister formation, rash, and other cutaneous abnormalities, because drug may cause severe cutaneous adverse reactions that may become life-threatening. At first sign of skin abnormality, stop drug therapy immediately and notify prescriber.
- Take seizure precautions according to facility policy, especially for patients with bacterial meningitis or CNS or renal disorders because of an increased risk of seizures with meropenem.
- Monitor patient with creatinine clearance of 10 to 26 ml/min for signs and symptoms of heart failure, renal failure, seizures, or shock.

## PATIENT TEACHING

- Tell patient to report immediately difficulty breathing, injection-site pain, skin changes (blister formation, rash), and sore mouth.
- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Remind patient that bloody or watery stools can occur 2 or

more months after antibiotic therapy and can be serious, requiring prompt treatment.

- Instruct patient to avoid hazardous activities until drug's CNS effects are known.

## mesalamine

**Apriso, Asacol, Asacol HD, Canasa, Delzicol, Lialda, Pentasa, Rowasa, Salofalk (CAN), sfRowasa**

### Class and Category

*Pharmacologic class:* Aminosalicylate

*Therapeutic class:* Anti-inflammatory

### Indications and Dosages

- *To treat and maintain remission of mildly to moderately active ulcerative colitis*

#### **DELAYED-RELEASE TABLETS (ASACOL), DELAYED-RELEASE CAPSULES (DELZICOL)**

**Adults.** *Initial:* 0.8 g three times daily for 6 wk.

*Maintenance:* 1.6 g daily in 2 to 4 divided doses.

- *To induce and maintain remission in patients with active mild to moderate ulcerative colitis.*

#### **DELAYED-RELEASE TABLETS (LIALDA)**

**Adults.** *Initial:* 2.4 or 4.8 g once daily with a meal for up to 8 wk. **Maintenance:** 2.4 g once daily with a meal.

➤ *To treat mildly to moderately active ulcerative colitis*

### **DELAYED-RELEASE TABLETS (ASACOL HD)**

**Adults.** 1,600 mg three times daily for 6 wk. *Maximum:* 4.8 g daily.

### **DELAYED-RELEASE TABLETS (ASACOL), DELAYED-RELEASE CAPSULES (DELZICOL)**

**Children age 5 and over weighing 54 to 90 kg ( 119 to 198 lb):** 27 to 44 mg/kg/day in two divided doses for 6 wk. *Maximum:* 2.4 g daily.

**Children age 5 and over weighing 33 to 54 kg (72.5 to 119 lb):** 37 to 61 mg/kg daily in two divided doses for 6 wk. *Maximum:* 2 g daily.

**Children age 5 and over weighing 17 to 33 kg (37.5 to 72.5 lb):** 36 to 71 mg/kg daily in two divided doses for 6 wks. *Maximum:* 1.2 g daily.

➤ *To maintain remission of ulcerative colitis*

### **E.R. CAPSULES (APRISO)**

**Adults.** 1.5 g once daily in morning.

➤ *To treat mild to moderate distal ulcerative colitis, proctitis, and proctosigmoiditis*

### **RECTAL SUSPENSION (ROWASA, SFROWASA)**

**Adults.** 4 g (60 ml) daily at bedtime for 3 to 6 wk.

➤ *To treat active ulcerative proctitis*

### **SUPPOSITORIES (CANASA)**

**Adults.** 1 g at bedtime for 3 to 6 wk.

## Mechanism of Action

May reduce inflammation by inhibiting the enzyme cyclooxygenase and decreasing production of arachidonic acid metabolites, which may be increased in patients with inflammatory bowel disease. Cyclooxygenase is needed to form prostaglandins from arachidonic acid. Prostaglandins mediate inflammatory activity and produce signs and symptoms of inflammation. Mesalamine also may reduce inflammation by interfering with leukotriene synthesis and inhibiting the enzyme lipoxygenase, both of which take part in inflammatory response.

## Contraindications

Hypersensitivity to mesalamine, other salicylates including aminosaliclates, or their components

## Interactions

### DRUGS

*azathioprine, 6-mercaptopurine:* Possibly increased risk for blood disorders

*nephrotoxic agents including NSAIDs:* Possibly increased risk of nephrotoxicity

## Adverse Reactions

**CNS:** Chills, confusion, depression, dizziness, emotional lability, fatigue, fever, **Guillain-Barré syndrome**, headache (severe), **intracranial hypertension**, peripheral

neuropathy, somnolence, transverse myelitis, tremor, vertigo, weakness

**CV:** Myocarditis, pericardial effusion, pericarditis

**EENT:** Blurred vision, dry mouth, rhinitis, swelling of eye, taste perversion, tinnitus

**GI:** Abdominal cramps or pain (severe), anal pruritus, anorexia, bloody diarrhea, cholecystitis, colitis, constipation, diarrhea, discoloration of feces, distention (abdomen), elevated liver enzymes, feeling of incomplete defecation, flatulence, gastritis, GI bleeding, hepatitis, hepatotoxicity, indigestion, jaundice, Kawasaki-like syndrome, liver failure or necrosis, mucous stools, nausea, pancreatitis, perforated peptic ulcer, rectal discharge or pain, vomiting

**GU:** Acute or chronic renal failure, interstitial nephritis, nephrogenic diabetes insipidus, nephrotoxicity, reversible oligospermia

**HEME:** Agranulocytosis, anemia, aplastic anemia, eosinophilia, granulocytopenia, leukopenia, lymphadenopathy, neutropenia, pancytopenia, thrombocytopenia

**MS:** Back pain, dysarthria, myalgia

**RESP:** Allergic alveolitis, Allergic alveolitis, asthma exacerbation, eosinophilic or interstitial pneumonitis, fibrosing alveolitis, pleuritis, pneumonitis

**SKIN:** Acne, alopecia, dryness, erythema including erythema nodosum, photosensitivity, psoriasis, pruritus, pyoderma gangrenosum, rash, Stevens-Johnson syndrome, urticaria

**Other:** Acute intolerance syndrome, anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS), gout, systemic lupus erythematosus or lupus-like syndrome

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm although it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, infant should be monitored for diarrhea.

# Nursing Considerations

**WARNING** Use mesalamine cautiously in patients with sulfite sensitivity. Some drug formulations contain sulfites, which may cause hypersensitivity reactions in these patients. Know that hypersensitivity reactions may affect internal organs such as the heart (myocarditis, pericarditis), kidneys (nephritis), liver (hepatitis), and lungs (pneumonitis), as well as cause hematologic adverse effects. If hypersensitivity is suspected, notify prescriber immediately, expect mesalamine to be discontinued, and provide supportive care, as ordered.

- Use mesalamine cautiously in patients with liver disease because hepatic dysfunction may occur. Monitor patient's liver enzymes, as ordered, for elevations.
- Expect to assess patient's renal function prior to the initiation of mesalamine therapy and then periodically throughout therapy, as ordered, because drug may cause renal impairment.

- Ensure that suppository is firm before inserting it. If it's too soft, chill in refrigerator for 30 minutes or run under cold water before removing wrapper. Moisten with water-soluble lubricant or tap water before insertion. Have patient retain suppository for 1 to 3 hours, as directed.
- Give rectal suspension at bedtime, and have patient retain for prescribed time—about 8 hours, if possible. Retention time ranges from 3.5 to 12 hours.
- Be aware that rectal suspension may darken slightly over time but that this change doesn't affect potency. Discard rectal suspension that turns dark brown.
- Assess patient for evidence of acute intolerance similar to flare-up of inflammatory bowel disease: acute abdominal cramps and pain, bloody diarrhea, and, possibly, fever, headache, and rash. If present, notify prescriber.
- Monitor patient's CBC with differential for eosinophilia, which may indicate an allergic reaction, and other hematological adverse reactions. Know that patients age 65 and over are at increased risk for blood dyscrasias such as agranulocytosis, neutropenia, and pancytopenia.
- Be aware that mesalamine may interfere with the measurement of urinary normetanephrine producing falsely elevated test results if the test is done by liquid chromatography with electrochemical detection.
- Monitor patient for signs and symptoms of acute intolerance syndrome, such as acute abdominal pain, bloody diarrhea, fever, headache, and rash. If suspected, expect to discontinue mesalamine therapy and provide supportive care, as ordered.
- Be aware that patients with preexisting skin conditions such as atopic dermatitis and atopic eczema are at higher risk for more severe photosensitivity reactions.

## **PATIENT TEACHING**

- Instruct patient taking oral drug to swallow tablets or capsules whole and not to break outer coating by cutting or chewing.
- Tell patient taking extended-release product to take it with a meal unless prescribed otherwise.
- Teach patient how to use rectal suspension or suppositories correctly. Emphasize shaking suspension bottle well before using. Tell patient not to break or cut suppository. Remind him to retain the suppository for 1 to 3 hours or longer, if possible. Caution patient not to use two suppositories

at the same time to make up for a missed dose. Make patient aware that suppository will cause staining if drug comes into direct contact with surfaces, such as clothing, floors, enamel, granite, marble, painted surfaces, and vinyl.

- Advise patient to notify prescriber immediately about abdominal cramps or pain, bloody diarrhea, fever, headache, or rash or any other adverse effects that are persistent, severe, or worsen during mesalamine therapy.
- Inform woman who is breastfeeding to monitor her infant for diarrhea and report if diarrhea occurs.
- Advise patient to take sun precautions such as using sunscreen and protective clothing while outdoors, as drug may cause photosensitivity reactions that could be severe, especially in patient with preexisting skin conditions.
- Tell patient to alert all prescribers of mesalamine therapy because of potential drug interactions, especially those drugs that increase sensitivity to sun and UV light.
- Alert patient that Apriso brand of drug contains phenylalanine, which can be harmful to patient if a diagnosis of phenylketonuria (PKU) exists. Patient should alert prescriber that he has PKU.

## metaxalone

### **Skelaxin**

## **Class and Category**

*Pharmacologic class:* Oxazolidinone derivative

*Therapeutic class:* Skeletal muscle relaxant

## **Indications and Dosages**

- *As adjunct to relieve discomfort caused by acute, painful musculoskeletal conditions*

## TABLETS

**Adults and children over age 12.** 800 mg three times daily or four times daily.

Route	Onset	Peak	Duration
P.O.	Usually in 1 hr	Unknown	4-6 hr

## Mechanism of Action

May depress CNS, causing sedation, which in turn may reduce skeletal muscle spasms to provide pain relief. Metaxalone doesn't directly relax tense skeletal muscles.

## Contraindications

Hypersensitivity to metaxalone or its components, significant hepatic or renal disease, tendency to develop drug-induced, hemolytic, or other anemias

## Interactions

### DRUGS

*CNS depressants (benzodiazepines, opioids, tricyclic antidepressants):* Increased CNS depression  
*serotonergic drugs (5-HT<sub>3</sub> receptor antagonists (especially fentanyl, meperidine, methadone), drugs that affect the serotonin neurotransmitter system (mirtazapine, tramadol, trazodone), MAO inhibitors, selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

## ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Dizziness, drowsiness, excitement, **CNS depression**, headache, insomnia, irritability, nervousness, restlessness

**GI:** Abdominal cramps or pain, GI upset, jaundice, **hepatotoxicity**, nausea, vomiting

**HEME:** **Hemolytic anemia**, **leukopenia**

**SKIN:** Pruritus, rash

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Drug should not be used in women who are or may become pregnant and especially during early pregnancy unless the benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy.

## Nursing Considerations

- Know that metaxalone may not be prescribed for women who are or may become pregnant unless potential benefits outweigh risks, because drug's effect on fetus is unknown.
- Expect to avoid giving metaxalone with food because food may increase CNS depression, especially in elderly patients.
- Monitor patient for excessive drowsiness, which may lead to respiratory depression.

- Monitor liver enzymes for elevations, especially in patients with preexisting hepatic disease.
- Monitor renal function test results, as prescribed, for signs of impaired renal function because drug is excreted by kidneys.
- Provide rest and other pain-relief measures.
- Store drug at 15° to 30°C (59° to 86°F).

## **PATIENT TEACHING**

- Advise patient to take metaxalone tablets exactly as prescribed and not to increase dosage or frequency.
- Instruct patient to take metaxalone tablets on an empty stomach.
- Caution patient to avoid hazardous activities, such as driving or operating machinery, until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other CNS depressants during therapy.
- Caution patient to consult prescriber before taking other drugs, such as allergy or cold preparations, antidepressants, opioid analgesics, or sleeping pills.
- Urge patient to notify prescriber if he notices itching or a rash, which may signify a hypersensitivity reaction, or if he develops signs of hepatotoxicity, such as flu-like symptoms, tiredness, nausea, or yellow skin.

## **metformin hydrochloride**

**Fortamet, Gen-Metformin (CAN),  
Glucophage, Glucophage XR,  
Glumetza, Glycon (CAN), Riomet**

# Class and Category

*Pharmacologic class:* Biguanide

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to reduce blood glucose level in type 2 diabetes mellitus*

### **ORAL SOLUTION (RIOMET), TABLETS (GLUCOPHAGE)**

**Adults.** *Initial:* 500 mg twice daily or 850 mg daily with meals, increased by 500 mg/wk or by 850 mg every 2 wk until desired response occurs. *Maximum:* 2,550 mg daily given in divided doses.

**Children ages 10 to 17.** 500 mg twice daily with meals, increased as prescribed by 500 mg/wk until desired response occurs. *Maximum:* 2,000 mg daily in divided doses.

### **E.R. TABLETS (FORTAMET, GLUCOPHAGE XR, GLUMETZA)**

**Adults and adolescents age 17 and over.**

*Initial:* 500 mg daily with evening meal. Increased as prescribed by 500 mg/wk. *Maximum:* 2,000 mg daily.

***DOSAGE ADJUSTMENT*** For patient taking ER tablets but not achieving adequate glucose control at maximum dose of 2,000 mg once daily, dosage split to 1,000 mg twice daily. If that does not achieve adequate control, patient switched to immediate release glucophage so dosage can be increased.

Route	Onset	Peak	Duration
P.O.	Unknown	Up to 2 wk	2 wk after drug discontinued

## Mechanism of Action

May promote storage of excess glucose as glycogen in the liver, which reduces glucose production. Metformin also may improve glucose use by adipose tissue and skeletal muscle by increasing glucose transport across cell membranes. This drug also may increase the number of insulin receptors on cell membranes and make them more sensitive to insulin. In addition, metformin modestly decreases blood total cholesterol and triglyceride levels.

## Contraindications

Acute or chronic metabolic acidosis, including diabetic ketoacidosis with or without coma; hypersensitivity to metformin or its components; severe renal disease (estimated glomerular filtration rate below 30 ml/min)

## Interactions

### DRUGS

*calcium channel blockers, corticosteroids, estrogens, isoniazid, nicotinic acid, oral contraceptives, phenothiazines, phenytoin, sympathomimetics, thiazide and other diuretics, thyroid drugs:* Possibly reduced effectiveness of metformin resulting in hyperglycemia  
*carbonic anhydrase inhibitors such as acetazolamide, dichlorphenamide, topiramate, zonisamide:* Possibly increased risk of lactic acidosis  
*cimetidine, dolutegravir, ranolazine, vandetanib:* Increased blood metformin level and possibly increased risk of lactic

acidosis

*insulin, sulfonylureas*: Increased risk of hypoglycemia

## ACTIVITIES

*alcohol use*: Increased risk of hypoglycemia and lactate formation

## Adverse Reactions

**CNS:** Headache

**EENT:** Metallic taste

**ENDO:** Hypoglycemia

**GI:** Abdominal distention, anorexia, constipation, diarrhea, flatulence, hepatic injury, indigestion, nausea, vomiting

**HEME:** Aplastic anemia, megaloblastic anemia, thrombocytopenia

**SKIN:** Photosensitivity, rash

**Other:** Lactic acidosis, vitamin B<sub>12</sub> deficiency (with immediate-release formulation), weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm although it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Caution women of childbearing age of the potential for unintended pregnancy as drug may cause ovulation in some anovulatory women.
- Advise women of childbearing age not wishing to conceive to use effective contraception measures while taking drug.

## Nursing Considerations

- Know that metformin should never be given to a patient with severe renal impairment (eGFR below 30 ml/min). Also be aware that metformin is not recommended for use in patients with hepatic impairment because of risk of lactic acidosis.
- Give metformin tablets with food, which decreases and slightly delays absorption, thus reducing risk of adverse GI reactions. Give E.R. tablets with evening meal; don't break or crush them.
- Expect prescriber to alter dosage if patient has a condition that decreases or delays gastric emptying, such as diarrhea, gastroparesis, GI obstruction, ileus, or vomiting.
- Expect to assess patient's estimated glomerular filtration rate (eGFR) at least annually. Anticipate that the elderly and those at increased risk for renal impairment may be tested more frequently. Be aware that initiation of metformin is not recommended in patients who have an eGFR between 45 and 60 ml/min.

**WARNING** Monitor patient closely for signs and symptoms of lactic acidosis that often are subtle and nonspecific, such as abdominal pain, increased somnolence, malaise, myalgias, and respiratory distress. Know that hypotension and resistant bradyarrhythmias have occurred with severe acidosis. Be aware that most cases of lactic acidosis have occurred in patients with significant renal impairment because metformin is substantially excreted by the kidneys. Other risk factors include being age 65 or older; certain drug interactions, such as carbonic anhydrase inhibitors; excessive alcohol intake; hepatic impairment; hypoxic

states; radiologic studies with contrast; and withholding of fluids and food, which increases risk of volume depletion. If lactic acidosis is suspected, notify prescriber, expect metformin to be immediately discontinued, and provide appropriate supportive care. Know that prompt hemodialysis may be needed to correct the acidosis and remove the accumulated metformin.

- Monitor patient's blood glucose level to evaluate drug effectiveness. Assess for hyperglycemia and the need for insulin during times of increased stress, such as infection and surgery.
- Withhold drug, as ordered, if patient becomes dehydrated or develops hypoxemia or sepsis because these conditions increase the risk of lactic acidosis.
- Know that iodinated contrast media used in radiographic studies increase risk of renal failure and lactic acidosis during metformin therapy. Expect to withhold drug for 48 hours before and after testing.
- Expect yearly measurements of patient's hematologic status as well as vitamin B<sub>12</sub> level. Be aware that vitamin B<sub>12</sub> deficiency has occurred with use of the immediate-release formulation of metformin.

## **PATIENT TEACHING**

- Instruct patient to take immediate-release metformin tablet at breakfast if taking drug once a day, or at breakfast and dinner if taking drug twice a day. Instruct him to take E.R. tablets once daily with evening meal and to swallow them whole without chewing or crushing.
- Direct patient to take drug exactly as prescribed and not to change the dosage or frequency unless instructed.
- Emphasize importance of checking blood glucose level regularly, controlling weight, exercising regularly, and following prescribed diet.
- Teach patient how to measure blood glucose level and recognize hyperglycemia and hypoglycemia. Urge him to notify prescriber of abnormal blood glucose level.
- Caution patient to avoid alcohol, which can increase the risk of hypoglycemia and lactic acidosis.

- Instruct patient to report early signs of lactic acidosis, including drowsiness, hyperventilation, malaise, and muscle pain.
- Advise patient to expect laboratory testing of glycosylated hemoglobin every 3 months until blood glucose is controlled.
- Alert women of childbearing age that metformin may cause ovulation in some premenopausal anovulatory women, which may lead to unintended pregnancy.

## methadone hydrochloride

### Dolophine, Methadose

## Class, Category, and Schedule

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid agonist

*Controlled substance schedule:* II

## Indications and Dosages

- *To manage opioid detoxification and then maintenance of opioid abstinence*

### DISPERSIBLE TABLETS, ORAL CONCENTRATE, ORAL SOLUTION, TABLETS

**Adults.** *Initial on day 1:* 20 to 30 mg as a single dose, followed by 5 to 10 mg 2 to 4 hr later, if needed. *Maximum for day 1:* 40 mg. *Maintenance:* Highly individualized with dosage adjustments made until opioid withdrawal symptoms have ceased for 24 hr. *Maximum:* 120 mg daily.

## I.V., I.M., OR SUBCUTANEOUS INJECTION

**Adults unable to take drug orally.** Highly individualized. If oral methadone had been used prior to hospitalization, dosage initially decreased by 50%.

- *To manage moderate to severe pain when a continuous, around-the-clock opioid analgesic is needed for an extended period of time and for which alternative treatment options are inadequate*

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 2.5 mg every 8 to 12 hr increased slowly, as needed, every 3 to 5 days. *Maximum:* 120 mg/day.

## I.V., I.M., OR SUBCUTANEOUS INJECTION

**Adults unable to take drug orally.** *Initial:* 2.5 to 10 mg every 8 to 12 hr increased slowly, as needed, every 3 to 5 days. *Maximum:* 120 mg/day.

**DOSAGE ADJUSTMENT** Addison's disease, debilitated patients, elderly patients, hypothyroidism, patients with severe hepatic or renal dysfunction, prostatic hyperplasia, or urethral stricture; and patients who are taking CNS depressants such as anxiolytics, hypnotics, neuroleptics, other opioids, or sedatives or who are suspected of alcohol or illicit drug use need individualized reduced dosages.

Route	Onset	Peak	Duration
P.O.	30-60 min	1.5-2 hr	4-6 hr
I.M., SubQ	10-20 min	1-2 hr	4-5 hr
I.V.	Unknown	15-30 min	Unknown

## Mechanism of Action

Binds with and activates opioid receptors (primarily mu receptors) in spinal cord and higher levels of CNS to produce analgesia and euphoric effects.

## Contraindications

Acute or severe bronchial asthma in unmonitored setting or in absence of resuscitative equipment, hypersensitivity to methadone or its components, paralytic ileus, significant respiratory depression

## Interactions

### DRUGS

*5-HT<sub>3</sub> receptor antagonists, certain muscle relaxants (cyclobenzaprine, metaxalone), drugs that affect the serotonin neurotransmitter system (mirtazapine, tramadol, trazodone), I.V. methylene blue, linezolid, MAO inhibitors, selective serotonin reuptake inhibitors (SSRIs), serotonin and norepinephrine reuptake inhibitors SNRIs), tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

*anticholinergics:* Possibly severe constipation leading to ileus; urine retention

*benzodiazepines, CNS depressants, other opioids, sedating antihistamines, tricyclic antidepressants:* Increased risk of significant respiratory depression and other life-threatening adverse effects

*desipramine:* Increased plasma desipramine levels

*didanosine, stavudine:* Decreased area under the concentration-time curve and peak levels of these drugs

*diuretics:* Decreased diuresis

*diuretics, laxatives, mineralocorticoid hormones:* Increased risk of electrolyte disturbances and prolonged QT interval

*CYP3A4, CYP2B6, CYP2C19, CYP2C9 inducers such as carbamazepine, phenobarbital, phenytoin, rifampin, St. John's wort:* Decreased methadone concentration, resulting in decreased efficacy or onset of withdrawal symptoms in patients dependent on methadone

*CYP3A4, CYP2B6, CYP2C19, CYP2C9, CYP2D6 inhibitors such as azole-antifungal agents, macrolide antibiotics, protease inhibitors, some selective serotonin reuptake inhibitors (fluvoxamine, sertraline):* Increased methadone concentration, resulting in increased or prolonged opioid effects that may result in a fatal overdose

*MAO inhibitors:* Possibly increased risk of opioid toxicity or serotonin syndrome

*mixed agonist-antagonist analgesics and partial agonist opioid analgesics such as buprenorphine, butorphanol, nalbuphine, pentazocine:* Possibly reduced analgesic effect of methadone; possibly precipitation of withdrawal symptoms

*muscle relaxants:* Possibly enhanced neuromuscular blocking action of skeletal muscle relaxants; increased degree of respiratory depression

*zidovudine:* Increased zidovudine levels possibly resulting in toxic effects

## **ACTIVITIES**

*alcohol use:* Increased CNS and respiratory depression, possibly hypotension

## **Adverse Reactions**

**CNS:** Agitation, amnesia, anxiety, asthenia, **coma**, confusion, decreased concentration, delirium, delusions, depression, dizziness, drowsiness, euphoria, fever, hallucinations, headache, insomnia, lethargy, light-

headedness, malaise, psychosis, restlessness, sedation, **seizures**, syncope, tremor

**CV:** **Bradycardia**, **cardiac arrest**, **cardiomyopathy**, edema, **heart failure**, **hypotension**, orthostatic hypotension, palpitations, phlebitis, **prolonged QT interval**, **shock**, tachycardia, **torsades de pointes**, T-wave inversion on ECG, **ventricular fibrillation or tachycardia**

**EENT:** Blurred vision, diplopia, dry mouth, glossitis, **laryngeal edema or laryngospasm**, miosis, nystagmus, rhinitis

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal cramps or pain, anorexia, biliary tract spasm, constipation, diarrhea, dysphagia, elevated liver enzymes, gastroesophageal reflux, hiccups, ileus and **toxic megacolon** (in patients with inflammatory bowel disease), indigestion, nausea, vomiting

**GU:** Amenorrhea, decreased ejaculate potency, decreased libido, difficult ejaculation, impotence, infertility, lack of menstruation, prolonged labor, urinary hesitancy, urine retention

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia

**RESP:** **Apnea**, **asthma exacerbation**, **atelectasis**, **bronchospasm**, depressed cough reflex, **hypoventilation**, **pulmonary edema**, **respiratory arrest or depression**, wheezing

**SKIN:** Diaphoresis, flushing

**Other:** **Allergic reaction**; **angioedema**; **hypokalemia**; **hypomagnesemia**; injection-site edema, pain, rash, or redness; physical and psychological dependence; weight gain; withdrawal symptoms

## Childbearing Considerations

## **PREGNANCY**

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Be aware that there are conflicting reports on whether Sudden Infant Death Syndrome occurs with an increased incidence in infants born to women treated with methadone during pregnancy.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.
- Pregnancy can decrease the terminal half-life of drug during the second and third trimesters resulting in possible withdrawal symptoms in some pregnant women. To avoid this, dosage may need to be increased or the dosing interval decreased to achieve therapeutic effect.

## **LABOR & DELIVERY**

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the newborn. Monitor newborn closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, monitor infant for excess sedation and respiratory depression.

## **REPRODUCTION**

- Chronic use of opioids may reduce fertility.

## Nursing Considerations

- Make sure opioid antagonist and equipment for administering oxygen and controlling respiration are nearby before giving methadone.
- Assess patient's current drug use, including all prescription and OTC drugs before therapy begins. Be aware that excessive use of methadone may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely.
- Be aware that use of methadone requires a Risk Evaluation and Mitigation Strategy (REMS) before drug can be dispensed, to ensure that the benefits outweigh the risks of abuse, addiction, and misuse.
- Know that benzodiazepine and other CNS depressant therapy should only be used concomitantly in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of methadone to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.
- Use extreme caution when administering methadone to patients with conditions accompanied by hypercapnia or hypoxia or decreased respiratory reserve such as asthma, chronic obstructive pulmonary disease or cor pulmonale, CNS depression or coma, kyphoscoliosis, myxedema, severe obesity, or sleep apnea syndrome. This is because methadone, even with usual therapeutic doses, may decrease respiratory drive while simultaneously increasing airway resistance to the point of apnea. Know that the peak respiratory depressant effect of methadone occurs later and persists longer than the peak analgesic effect. Monitor patient's respiratory status closely, especially when initiating drug or following a dosage increase.

**WARNING** Give drug cautiously to patients at risk for a prolonged QT interval, such as those with cardiac hypertrophy, hypokalemia, or hypomagnesemia; those with a history of cardiac conduction abnormalities; and those taking diuretics or medications that affect cardiac conduction.

- Dilute oral concentrate with water or another liquid to volume of at least 30 ml, but preferably to 90 ml or more, before administration. Dissolve dispersible tablets in 120 ml of water or another liquid before giving. Know that the dispersible tablet may not completely dissolve in water. If a residue remains in the cup after initial administration with water, add a small amount of liquid to the cup and give to patient to drink to ensure all of the drug has been ingested.
- Monitor patient for expected excessive confusion, drowsiness, or unsteadiness during first 3 to 5 days of therapy, and notify prescriber if effects continue to worsen or persist beyond this time.

**WARNING** Monitor circulatory and respiratory status carefully and often during methadone therapy, especially when drug therapy is initiated and when patient is being converted to methadone, because cardiac arrest, circulatory or respiratory depression, hypotension, respiratory arrest, and shock, can develop. Life-threatening respiratory depression can occur even when drug is being used as prescribed and is not abused or misused. Be especially vigilant with cachectic, debilitated, and elderly patients, who are at higher risk for developing respiratory depression. Assess patient for excessive or persistent sedation; dosage may need to be adjusted.

- Be aware that patients tolerant to other opioids may be incompletely tolerant to methadone. A high degree of “opioid tolerance” does not eliminate the possibility of methadone toxicity. Some patients have died during conversion from chronic high-dose therapy with other opioid agonists. Monitor patient closely during the conversion process.
- Watch for drug tolerance, especially in patients with a history of chronic drug abuse, because methadone can cause physical and psychological dependence.
- Monitor patient for pain because maintenance dosage doesn’t provide pain relief; patients with tolerance to opiate agonists, including those with chronic cancer pain, may require a higher dosage.
- Know that chronic maternal use of methadone during pregnancy can result in NOWS, which may be life-threatening, if not recognized and treated appropriately. Monitor patients who are pregnant or who have

liver or renal impairment for increased adverse effects from methadone because drug may have a prolonged duration and cumulative effect in these patients. Methadone may prolong labor by reducing duration, frequency, strength of uterine contractions, so expect dosage to be tapered before third trimester of pregnancy. Breast-feeding mothers on maintenance therapy put their infants at risk of withdrawal symptoms if they abruptly stop breastfeeding or discontinue methadone therapy. Methadone also accumulates in CNS tissue, increasing the risk of seizures in infants.

- Check plasma amylase and lipase levels in patients who develop biliary tract spasms because levels may increase up to 15 times normal. Notify prescriber immediately of any significant or sustained increase.
- Monitor patients who have head injuries or other conditions that may increase intracranial pressure (ICP) because methadone may further increase ICP.
- Assess patient for withdrawal symptoms and tolerance to therapy because physiologic dependence can occur with long-term methadone use. Avoid abrupt discontinuation because withdrawal symptoms will occur within 3 to 4 days after last dose.
- Monitor patients, especially the elderly, for cardiac arrhythmias, hypotension, hypovolemia, orthostatic hypotension, and vasovagal syncope because methadone may produce cholinergic effects in patients with cardiac disease, resulting in bradycardia and peripheral vasodilation; dosage decrease may be indicated.
- Monitor patients with prostatic hypertrophy, renal disease, or urethral stricture for urine retention and oliguria because methadone can increase tension of detrusor muscle.
- Be prepared to treat patient's symptoms of anxiety; be aware that anxiety may be confused with symptoms of opioid abstinence and that methadone doesn't have antianxiety effects.
- Monitor patients with seizure disorders because methadone may induce or aggravate seizure activity.

**WARNING** Know that many drugs may interact with opioids like methadone to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once

because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care. Also be aware that concomitant use of methadone with CYP3A4, CYP2B6, CYP2C19, or CYP2D6 inhibitors or discontinuation of concomitantly used CYP3A4, CYP2B6, CYP2C19, or CYP2C9 inducers can result in a fatal overdose.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If confirmed, expect to administer corticosteroids and wean patient off methadone, if possible.

## **PATIENT TEACHING**

- Inform patient that misuse of drug either by taking excessive amounts or by taking drug for prolonged periods of time can lead to addiction, overdose, or even death. Therefore, tell patient to take drug exactly as prescribed and for the shortest time possible.
- Instruct patient taking oral concentrate form of methadone to dilute it with water or another liquid to a volume of at least 30 ml, and preferably to 90 ml or more, before administration.
- Instruct patient to dissolve dispersible tablets in 120 ml of water or other liquid immediately before administration. Alert patient that if water is used and residue is left in the cup after ingesting, he should add a little more liquid to the cup and drink to ensure all the drug was consumed.
- Advise patient to notify prescriber of all other drugs he's currently taking, including benzodiazepines, and to avoid alcohol and other depressants, such as sleeping pills and tranquilizers, because they may increase drug's CNS depressant effects and cause severe respiratory depression that could result in death.
- Inform patient that abrupt cessation of methadone therapy can precipitate withdrawal symptoms. Urge him to notify prescriber if he develops any concerns over therapy.
- Urge patient to notify prescriber if he experiences dizziness, light-headedness, palpitations, or syncope, which may be caused by methadone-induced arrhythmias.

- Instruct patient to avoid potentially hazardous activities or those that require mental alertness because methadone therapy may cause drowsiness or sleepiness.
- Teach patient to change positions slowly to minimize the effects of orthostatic hypotension.
- Instruct patient to notify prescriber of worsening or breakthrough pain because dosage may need to be adjusted.
- Instruct female patient to notify prescriber immediately if she becomes pregnant during methadone therapy because drug may cause physical dependence in fetus and withdrawal symptoms in neonate.
- Instruct patient or parents to keep methadone out of the reach of children because accidental ingestion can be fatal.
- Inform patient that long-term use of opioids like methadone may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms.
- Advise patient that drug may cause severe constipation and to take measures to avoid constipation. If unresolved or severe, tell patient to seek medical attention.

## methimazole

### Tapazole

## Class and Category

*Pharmacologic class:* Thyroid hormone antagonist

*Therapeutic class:* Antithyroid

## Indications and Dosages

- *To treat hyperthyroidism*

## TABLETS

**Adults and adolescents.** *Initial:* 15 mg daily for mild hyperthyroidism, 30 to 40 mg daily for moderate hyperthyroidism, and 60 mg daily for severe hyperthyroidism given in divided doses three times daily 8 hr apart for 6 to 8 wk or until euthyroid level is reached. *Maintenance:* 5 to 15 mg daily.

**Children.** *Initial:* 0.4 mg/kg daily in divided doses three times daily 8 hr apart. *Maintenance:* 0.2 mg/kg daily.

Route	Onset	Peak	Duration
P.O.	5 days	7 wk	Unknown

## Mechanism of Action

Directly interferes with thyroid hormone synthesis in the thyroid gland by inhibiting iodide incorporation into thyroglobulin. Iodination of thyroglobulin is an important step in synthesizing the thyroid hormones thyroxine and triiodothyronine. Eventually, thyroglobulin is depleted and the circulating thyroid hormone level drops.

## Contraindications

Breastfeeding, hypersensitivity to methimazole or its components

## Interactions

### DRUGS

*beta blockers:* Possibly increased blood levels of these drugs when patient becomes euthyroid

*digoxin*: Possibly increased blood digoxin level when patient becomes euthyroid

*oral anticoagulants*: Possibly action of oral anticoagulants may be potentiated

*theophylline*: Increased blood theophylline level when patient becomes euthyroid

## Adverse Reactions

**CNS**: Drowsiness, headache, paresthesia, vertigo

**CV**: Edema

**EENT**: Loss of taste

**ENDO**: Hypothyroidism

**GI**: Diarrhea, indigestion, jaundice, nausea, vomiting

**HEME**: **Agranulocytosis, aplastic anemia, leukopenia, thrombocytopenia**

**MS**: Arthralgia, myalgia

**SKIN**: Alopecia, pruritus, rash, skin discoloration, urticaria

**Other**: Lupus-like symptoms, lymph-adenopathy

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm as it crosses the placental barrier and can induce goiter and even cretinism in the developing fetus. In addition, rare cases of congenital defects have occurred in infants born to mothers who received the drug during pregnancy.
- If pregnancy occurs, it is recommended that drug be discontinued and an alternative drug substituted during the pregnancy.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is contraindicated during drug therapy.

# Nursing Considerations

- Closely monitor thyroid function test results during methimazole therapy.
- Check CBC results to detect abnormalities caused by inhibition of myelopoiesis.
- Watch for signs and symptoms of hypothyroidism, such as cold intolerance, depression, and edema.
- Be aware that hyperthyroidism may increase metabolic clearance of beta blockers and theophylline and that dosages of these drugs may need to be reduced as the patient's thyroid condition becomes corrected.

## PATIENT TEACHING

- Instruct patient to take drug with meals to avoid adverse GI reactions.
- Explain about possible hair loss or thinning during and for months after therapy.
- Instruct patient to notify prescriber immediately about cold intolerance, fever, sore throat, tiredness, and unusual bleeding or bruising.

**methocarbamol**

**Robaxin, Robaxin 750**

## Class and Category

*Pharmacologic class:* Carbamate derivative

*Therapeutic class:* Skeletal muscle relaxant

## Indications and Dosages

- *As adjunct to relieve discomfort caused by acute, painful musculoskeletal conditions*

## **TABLETS**

**Adults.** *Initial:* 1,500 mg four times daily for 2 to 3 days; for severe discomfort 8,000 mg daily. *Maintenance:* 1,000 mg four times daily (Robaxin). Alternatively, 750 mg every 4 hr, or 1,500 mg three times daily (Robaxin 750).

## **I.M. INJECTION, I.V. INJECTION**

**Adults.** *Initial:* 1 g followed by 1 g every 8 hours, if needed, for a total of 3 g in 24 hr. Then, 1 g every 8 hr for no longer than 2 more days, if needed. I.V. injected at a rate of 300 mg/min. I.M. dosage split with no more than 500 mg injected into each gluteal site. *Maximum:* 3 g daily for no longer than 3 days.

- *To provide supportive therapy for tetanus*

## **TABLETS**

**Adults and adolescents.** Up to 24 g daily in divided doses given by NG tube.

## **I.V. INFUSION OR INJECTION**

**Adults.** *Initial:* 1 to 2 g directly into I.V. tubing slowly, at a maximum rate of 3 ml/min, followed by an additional 1 to 2 g by I.V. infusion at a maximum rate of 300 mg/min for a total dose of up to 3 g. Dosing procedure repeated every 6 hr, as needed, until nasogastric tube can be inserted and oral therapy begun.

**Children.** *Initial:* 15 mg/kg at a rate of 180 mg/m<sup>2</sup> and repeated every 6 hr, as needed. *Maximum:* 1.8 g/m<sup>2</sup>/day for 3 days only.

Route	Onset	Peak	Duration
P.O.	30 min	Unknown	Unknown
I.V.	Immediate	Unknown	Unknown

## Mechanism of Action

May depress CNS, which leads to sedation and reduced skeletal muscle spasms. Methocarbamol also alters perception of pain.

## Contraindications

Hypersensitivity to methocarbamol or its components

## Interactions

### DRUGS

*anticholinesterase drugs:* Possibly inhibit the effect of these drugs such as pyridostigmine bromide.

*CNS depressants:* Increased CNS depression

### ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Dizziness, drowsiness, fever, headache, light-headedness, **seizures (I.V.)**, syncope, vertigo, weakness

**CV:** **Bradycardia**, **hypotension**, and thrombophlebitis (parenteral)

**EENT:** Blurred vision, conjunctivitis, diplopia, metallic taste, nasal congestion, nystagmus

**GI:** Nausea

**GU:** Black, brown, or green urine

**SKIN:** Flushing, pruritus, rash, urticaria

**Other:** **Anaphylaxis (parenteral), angioedema,** injection-site irritation or pain (I.M.), injection-site sloughing (I.V.)

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm. Reports of congenital abnormalities following in utero exposure to drug have occurred.
- Drug should not be given to women who are or may become pregnant, especially early in pregnancy unless the benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Crush methocarbamol tablets and mix with water or saline solution for administration by NG tube.
- Give I.V. form directly undiluted into the vein or give through infusion line at 3 ml/min. To prepare solution for infusion, add 10 ml to no more than 250 ml D<sub>5</sub>W or normal saline solution. Infuse at no more than 300 mg (3 ml)/min to avoid hypotension and seizures.
- Keep patient recumbent during I.V. administration and for at least 15 minutes afterward. Then have him rise slowly.
- Monitor I.V. site regularly for signs of phlebitis.
- Inject I.M. form deep into large muscle, such as the gluteus. Give no more than 5 ml/dose every 8 hours. One dose is usually adequate.

- Don't give methocarbamol by subcutaneous route.
- Keep antihistamines, corticosteroids, and epinephrine available in case patient experiences anaphylactic reaction.
- Be aware that the parenteral dosage form shouldn't be used in patients with renal dysfunction because the polyethylene glycol 300 vehicle is nephrotoxic.

## **PATIENT TEACHING**

- Tell patient to take drug exactly as prescribed.
- Advise patient to take drug with food or milk to avoid nausea.
- Inform patient that urine may turn black, brown, or green until methocarbamol is discontinued.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to avoid alcohol and other CNS depressants during therapy.

**methotrexate**

**(amethopterin)**

**Otrexup PFS, Rasuvo, Reditrex,  
Rheumatrex, Xatmep**

**methotrexate sodium**

**Trexall**

## **Class and Category**

*Pharmacologic class:* Folate antagonist (antimetabolite)  
*Therapeutic class:* Antineoplastic

## Indications and Dosages

- *To treat severe psoriasis unresponsive to other therapy*

### **TABLETS (RHEUMATREX, TREXALL)**

**Adults.** 2.5 mg every 12 hr for 3 doses/wk, increased as ordered by 2.5 mg/wk. Alternatively, 7.5 mg once weekly. *Maximum:* 30 mg/wk.

### **I.V. OR I.M INJECTION (METHOTREXATE SODIUM), SUBCUTANEOUS INJECTION (OTREXUP PFS, RASUVO, REDITREX)**

**Adults.** 10 to 25 mg as a single dose weekly. I.V. injection rate dependent upon dose. Follow manufacturer instructions. *Maximum:* 30 mg weekly.

- *To treat severe rheumatoid arthritis unresponsive to other therapy*

### **TABLETS (RHEUMATREX, TREXALL)**

**Adults.** 2.5 every 12 hr for 3 doses/wk, increased as ordered by 2.5 mg/wk. Alternatively, 7.5 mg once weekly. *Maximum:* 20 mg/wk.

### **SUBCUTANEOUS INJECTION (OTREXUP PFS, RASUVO, REDITREX TREXALL)**

**Adults.** 7.5 mg once weekly, then gradually increased to achieve an optimal response. *Maximum:* 20 mg/wk.

- *To treat active polyarticular juvenile idiopathic arthritis unresponsive to other therapy*

**ORAL SOLUTION (XATMEP), I.M. INJECTION (METHOTREXATE SODIUM), SUBCUTANEOUS INJECTION (OTREXUP PFS, RASUVO, REDITREX), TABLETS (RHEUMATREX, TREXALL)**

**Children ages 2 to 16.** *Initial:* 10 mg/m<sup>2</sup> once weekly, increased gradually, as needed.

Route	Onset	Peak	Duration
P.O., I.V., I.M.	3–6 wk	Unknown	Unknown
SubQ	Unknown	Unknown	Unknown

## Mechanism of Action

May exert immunosuppressive effects by inhibiting replication and function of T and possibly B lymphocytes. Methotrexate also slows rapidly growing cells, such as epithelial skin cells in psoriasis. This action may result from the drug's inhibition of dihydrofolate reductase, the enzyme that reduces folic acid to tetrahydrofolic acid. Inhibition of tetrahydrofolic acid interferes with DNA synthesis and cell reproduction in rapidly proliferating cells.

## Contraindications

*For all conditions:* Breastfeeding, hypersensitivity to methotrexate or its components, pregnancy; *For treatment of psoriasis or rheumatoid arthritis:* alcoholism; alcoholic liver disease; chronic liver disease; laboratory evidence or overt immunodeficiency syndromes; preexisting blood dyscrasias such as bone marrow hypoplasia, leukopenia, significant anemia, or thrombocytopenia

# Interactions

## DRUGS

*bone marrow depressants*: Possibly increased bone marrow depression

*chloramphenicol, nonabsorbable broad spectrum antibiotics, tetracycline*: Possibly decreased methotrexate absorption

*co-trimoxazole*: Possibly increased bone marrow suppression

*folic acid*: Possibly decreased effectiveness of methotrexate

*hepatotoxic drugs*: Increased risk of hepatotoxicity

*NSAIDs, penicillins, phenylbutazone, phenytoin, probenecid, salicylates, sulfonamides*: Increased risk of methotrexate toxicity

*theophylline*: Possibly increased risk of theophylline toxicity

*vaccines*: Risk of disseminated infection with live-virus vaccines, risk of suppressed response to killed-virus vaccines

## ACTIVITIES

*alcohol use*: Increased risk of hepatotoxicity

# Adverse Reactions

**CNS**: Aphasia, **cerebral thrombosis**, chills, dizziness, drowsiness, fatigue, fever, headache, hemiparesis, **leukoencephalopathy**, malaise, paresis, **seizures**

**CV**: Chest pain, **deep vein thrombosis**, **hypotension**, **pericardial effusion**, **pericarditis**, **thromboembolism**

**ENDO**: Gynecomastia

**EENT**: Blurred vision, conjunctivitis, gingivitis, glossitis, pharyngitis, stomatitis, transient blindness, tinnitus

**GI:** Abdominal pain, anorexia, **cirrhosis**, diarrhea, elevated liver enzymes, enteritis, **GI bleeding** and ulceration,

**hepatitis**, **hepatotoxicity**, nausea, **pancreatitis**, vomiting

**GU:** Cystitis, hematuria, infertility, menstrual dysfunction, nephropathy, **renal failure**, **tubular necrosis**, vaginal discharge

**HEME:** Anemia, **aplastic anemia**, **leukopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, dysarthria, myalgia, stress fracture

**RESP:** Dry nonproductive cough, dyspnea, **interstitial pneumonitis**, pneumonia, **pulmonary fibrosis or failure**, **pulmonary infiltrates**

**SKIN:** Acne, alopecia, altered skin pigmentation, ecchymosis, **erythema multiforme**, **exfoliative dermatitis**, furunculosis, necrosis, photosensitivity, pruritus, psoriatic lesions, rash, **Stevens-Johnson syndrome**, telangiectasia, **toxic epidermal necrolysis**, ulceration, urticaria

**Other:** **Anaphylaxis**, increased risk of infection, lymphadenopathy, **lymphoproliferative disease**

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm such as embryotoxicity and fetal defects or death.
- Drug is contraindicated in pregnant women with psoriasis or rheumatoid arthritis and should be used in the treatment of neoplastic disease only if benefit to the mother outweighs the risk to the fetus.
- A negative pregnancy test should be obtained before drug therapy is started.

### LACTATION

- Drug may be present in breast milk.
- Breastfeeding is contraindicated during drug therapy because of the potential for serious adverse reactions in breast fed infants.

## REPRODUCTION

- Because of fetal harm, both partners should avoid conception during and after drug is discontinued for 3 months for male patients and for at least one ovulatory cycle after therapy for female patients.
- Drug may cause fertility impairment, menstrual dysfunction, and oligospermia during and for a short period after drug is discontinued.

## Nursing Considerations

- Follow facility policy for preparing and handling drug; parenteral form poses a risk of carcinogenicity, mutagenicity, and teratogenicity. Avoid skin contact.
- Use only preservative-free formulation of methotrexate when administering high-dose therapy.
- Monitor results of CBC, chest x-ray, liver and renal function tests, and urinalysis before and during treatment.
- Administer subcutaneous injection into patient's abdomen or thigh.
- Increase patient's fluid intake to 2 to 3 L daily, unless contraindicated, to reduce the risk of adverse GU reactions.
- Assess patient for bleeding and infection.

**WARNING** Expect renal impairment to severely alter drug elimination.

- Be aware that high doses of methotrexate can impair renal elimination by forming crystals that obstruct urine flow. To prevent drug precipitation, alkalinize patient's urine with sodium bicarbonate tablets, as ordered.
- Follow standard precautions because drug can cause immunosuppression.
- Be aware that if patient becomes dehydrated from vomiting, prescriber should be notified, and expect to withhold drug until patient recovers.

- Be aware that if patient receives high doses of drug, leucovorin should be kept readily available as antidote.
- Be aware that methotrexate resistance may develop with prolonged use.

## **PATIENT TEACHING**

- Prepare a calendar of treatment days for patient, and emphasize importance of following instructions exactly.
- Advise parents or caregivers administering oral solution form of methotrexate to use a calibrated measuring device and never to use a household measuring teaspoon because it is not an accurate measuring device.
- Teach patient prescribed weekly subcutaneous injections, how to administer the injection using the single-dose auto-injector. Tell him to give the injection into his abdomen or thigh and to rotate injection sites.
- Instruct patient to avoid alcohol during methotrexate therapy.
- Encourage frequent mouth care to reduce the risk of mouth sores.
- Instruct patient to use sunblock when exposed to sunlight.
- Advise patient to notify prescriber about bruising, chills, cough, dark or bloody urine, fever, mouth sores, shortness of breath, sore throat, and yellow skin or eyes.
- Urge women of childbearing age to use reliable contraception during methotrexate therapy.

**methoxypolyethylene  
glycol-epoetin beta**

**Mircera**

## **Class and Category**

*Pharmacological class:* Erythropoietin stimulating protein  
*Therapeutic class:* Antianemic

## Indications and Dosages

- *To treat anemia associated with chronic renal failure in dialysis-dependent and dialysis-independent patients*

### I.V. INJECTION, SUBCUTANEOUS INJECTION

**Adults not currently being treated with an erythropoiesis-stimulating agent.** *Initial:* 0.6 mcg/kg every 2 wk, increased or decreased by 25% monthly as needed. *Maintenance:* Twice that of the every-two-week dose every 4 wk and subsequently titrated as necessary.

**Adults stabilized on less than 8,000 units/wk of epoetin alfa or 40 mcg/wk of darbepoetin alfa.** 60 mcg every 2 wk or 120 mcg every 4 wk.

**Adults stabilized on 8,000 to 16,000 units/wk of epoetin alfa or 40 to 80 mcg/wk of darbepoetin alfa.** 100 mcg every 2 wk or 200 mcg every 4 wk.

**Adults stabilized on more than 16,000 units/wk of epoetin alfa or more than 80 mcg/wk of darbepoetin alfa.** 180 mcg every 2 wk or 360 mcg every 4 wk.

### I.V. INJECTION

**Children ages 5 to 17 on hemodialysis who are converting from another erythropoiesis-stimulating agent (ESA) after hemoglobin level stabilized with an ESA.** 4 x previous weekly epoetin alfa dose (units)/125 or 4 x previous weekly darbepoetin alfa dose (mcg)/0.55.

***DOSAGE ADJUSTMENT*** If hemoglobin increase is greater than 1 g/dl during any 2-wk period or hemoglobin is approaching

or exceeding 11 g/dl in adult patients on dialysis or exceeds 10 g/dl in adult patients not on dialysis, dosage reduced or interrupted. If hemoglobin continues to increase despite this reduction, drug discontinued until hemoglobin begins to decrease; then drug restarted at a dose 25% less than previously given. If hemoglobin doesn't increase by 1 g/dl after 4 wk of therapy in adult patients, dosage increased by 25%.

Route	Onset	Peak	Duration
I.V., SubQ	7-15 days	72 hr	72 hr

## Mechanism of Action

Stimulates release of reticulocytes from bone marrow into the bloodstream, where they develop into mature RBCs.

## Incompatibilities

Don't mix methoxypolyethylene glycol-epoetin beta with any other drug.

## Contraindications

Hypersensitivity to methoxypolyethylene glycolepoetin beta or its components, pure red cell aplasia, uncontrolled hypertension

## Interactions

### DRUGS

None reported

# Adverse Reactions

**CNS:** CVA, headache, seizures

**CV:** Chest pain, congestive heart failure, deep vein thrombosis, hypertension, hypotension, MI, tachycardia, vascular access thrombosis

**EENT:** Nasopharyngitis

**GI:** Constipation, diarrhea, GI bleeding, vomiting

**GU:** UTI

**HEME:** Severe anemia including pure red cell aplasia

**MS:** Back or limb pain, muscle spasms

**RESP:** Bronchospasms, cough, upper respiratory tract infection

**SKIN:** Erythema, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, antibody formation to drug

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use drug cautiously in patients who have conditions that could decrease or delay response to drug, such as aluminum intoxication, folic acid deficiency, hemolysis, infection, inflammation, iron deficiency, malignant neoplasm, osteitis (birrosa cystica), or vitamin B<sub>12</sub> deficiency.
- Also use drug cautiously in patients with a cardiovascular disorder caused by a history of seizures, hypertension, vascular disease. Also use cautiously in patients with a hematologic disorder, such as hypercoagulation, myelodysplastic syndrome, or sickle cell disease.
- Be aware that if patient's blood pressure is difficult to control even with dietary measures or drug therapy, dose of methoxypolyethylene glycol-epoetin beta should be reduced or drug withheld until blood pressure is controlled.
- Don't shake vial during preparation to avoid denaturing glycoprotein, inactivating drug. Protect prefilled syringes and vials from light by storing in original cartons.
- Discard unused portion of single-dose vial because it contains no preservatives.

**WARNING** Know that target hemoglobin shouldn't exceed 11 g/dl because it increases risk of life-threatening adverse cardiovascular effects.

- Monitor drug effectiveness by checking hemoglobin every 2 weeks until stabilized and maintenance dose has been established. Then expect hemoglobin to be monitored at least monthly unless dosage adjustment is needed.
- Expect to give an iron supplement because iron requirements rise when erythropoiesis consumes existing iron stores.
- Notify prescriber if patient has sudden loss of response to drug, evidenced by low reticulocyte count or severe anemia. Anti-erythropoietin antibody-related anemia may be present, which requires stopping drug and any other erythropoietic proteins.
- Take seizure precautions, especially during the first couple months of therapy.
- Keep in mind the risk of hypertensive or thrombotic complications increases if hemoglobin rises more than 1 g/dl over 2 weeks.

## **PATIENT TEACHING**

- Teach patient how to administer drug and how to dispose of needles properly. Caution against reusing needles.
- Stress importance of complying with dosage regimen and keeping follow-up laboratory and medical appointments.
- Review possible adverse reactions, and urge patient to notify prescriber about chest pain, headache, hives, rapid heartbeat, rash, seizures, shortness of breath, or swelling.

**WARNING** Warn patient to stop taking drug immediately if an allergic reaction occurs and notify prescriber. If serious, tell patient to seek emergency treatment.

- Advise patient that the risk of seizures is highest during the first couple of months of methoxypolyethylene glycol-epoetin beta therapy. Urge him to avoid hazardous activities during this time.
- Encourage patient to eat iron-rich foods.

**methyldopa**

**methyldopate hydrochloride**

## **Class and Category**

*Pharmacologic class:* Central alpha agonist

*Therapeutic class:* Antihypertensive

## **Indications and Dosages**

➤ *To manage hypertension*

**ORAL SUSPENSION, TABLETS (METHYLDOPA)**

**Adults.** *Initial:* 250 mg twice daily or three times daily for first 48 hr, decreased or increased as needed after 2 days with adjustments made no less than every 2 days.

*Maintenance:* 500 to 2,000 mg daily in divided doses twice daily to four times daily. *Maximum:* 3,000 mg daily.

**Children.** *Initial:* 10 mg/kg daily in divided doses twice daily to four times daily for first 48 hr, decreased or increased as needed after 2 days with adjustments made no less than every 2 days. *Maximum:* 65 mg/kg or 3,000 mg daily, whichever is less.

➤ *To treat hypertensive crisis*

## **I.V. INFUSION (METHYLDOPATE HYDROCHLORIDE)**

**Adults.** 250 to 500 mg diluted in D<sub>5</sub>W and infused over 30 to 60 min every 6 hr. *Maximum:* 1,000 mg every 6 hr.

**Children.** 20 to 40 mg/kg/day in divided doses every 6 hr and infused over 30 to 60 min. *Maximum:* 65 mg/kg or 3,000 mg daily, whichever is less.

Route	Onset	Peak	Duration
P.O.	Unknown	4-6 hr*	12-24 hr†
I.V.	Unknown	4-6 hr	10-16 hr

\* For single dose; 2 to 3 days for multiple doses.

† For single dose; 24 to 48 hr for multiple doses.

## **Mechanism of Action**

Is decarboxylated in the body to produce alpha-methylnorepinephrine, a metabolite that stimulates central inhibitory alpha-adrenergic receptors. This action may reduce blood pressure by decreasing sympathetic stimulation of heart and peripheral vascular system.

# Incompatibilities

Don't administer methyldopa through same I.V. line as barbiturates or sulfonamides.

# Contraindications

Active hepatic disease, hypersensitivity to methyldopa or its components, impaired hepatic function from previous methyldopa therapy, use within 14 days of MAO inhibitor

# Interactions

## DRUGS

*anesthetics*: Possibly enhanced effect requiring reduced dosage of anesthetics

*antihypertensives*: Increased hypotension

*CNS depressants*: Possibly increased CNS depression

*ferrous gluconate, ferrous sulfate*: Decreased bioavailability of methyldopa

*lithium*: Increased risk of lithium toxicity

*MAO inhibitors*: Possibly hallucinations, headaches, hyperexcitability, and severe hypertension

## ACTIVITIES

*alcohol use*: Possibly increased CNS depression

# Adverse Reactions

**CNS**: Decreased concentration, depression, dizziness, drowsiness, fever, headache, involuntary motor activity, memory loss (transient), nightmares, paresthesia, Parkinsonism, sedation, vertigo, weakness

**CV:** Angina, **bradycardia**, edema, **heart failure**, **myocarditis**, orthostatic hypotension  
**EENT:** Black or sore tongue, dry mouth, nasal congestion  
**ENDO:** Gynecomastia  
**GI:** Constipation, diarrhea, flatulence, **hepatic necrosis**, **hepatitis**, jaundice, nausea, **pancreatitis**, vomiting  
**GU:** Decreased libido, impotence  
**HEME:** **Agranulocytosis**, **hemolytic anemia**, **leukopenia**, positive Coombs' test, positive tests for ANA and rheumatoid factor, **thrombocytopenia**  
**SKIN:** Eczema, rash, urticaria  
**Other:** Weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- For I.V. infusion, add methyldopate to 100 ml of D<sub>5</sub>W and administer over 30 to 60 minutes.
- Expect to monitor CBC and differential results before and periodically during methyldopa therapy.
- Monitor blood pressure regularly during therapy.

- Monitor results of Coombs' test; a positive result after several months of treatment indicates that patient has hemolytic anemia. Expect to discontinue drug.
- Assess for edema and weight gain. If they develop, give a diuretic, as prescribed.
- Notify prescriber if patient has signs of heart failure (dyspnea, edema, hypertension) or involuntary, rapid, jerky movements.
- Be aware that hypertension may return within 48 hours after stopping drug.

## **PATIENT TEACHING**

- Instruct patient to take methyldopa exactly as prescribed and not to skip a dose. Explain that hypertension can return within 48 hours after stopping drug.
- Suggest that patient take drug at bedtime to minimize daytime drowsiness.
- Instruct patient to weigh himself daily and to report a gain of more than 5 lb (2.3 kg) in 2 days.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Direct patient to notify prescriber about bruising, chest pain, fever, involuntary jerky movements, prolonged dizziness, rash, and yellow eyes or skin.
- Caution patient not to stop drug abruptly; doing so may cause withdrawal symptoms, such as headache, hypertension, increased sweating, nausea, and tremor.

**methylnaltrexone bromide**

**Relistor**

## Class and Category

*Pharmacologic class:* Peripheral mu-opioid receptor antagonist

*Therapeutic class:* GI effector

## Indications and Dosages

- *To treat opioid-induced constipation in patients receiving palliative care and not responsive to laxative therapy.*

### SUBCUTANEOUS INJECTION

**Adults weighing more than 114 kg (251 lb).** 0.15 mg/kg every other day, as needed. *Maximum:* 0.15 mg/kg daily.

**Adults weighing 62 to 114 kg (136 to 251 lb).** 12 mg every other day, as needed. *Maximum:* 12 mg daily.

**Adults weighing 38 to less than 62 kg (84 to less than 136 lb).** 8 mg every other day, as needed. *Maximum:* 8 mg daily.

**Adults weighing less than 38 kg (84 lb).** 0.15 mg/kg every other day, as needed. *Maximum:* 0.15 mg/kg daily.

***DOSAGE ADJUSTMENT*** For patient with moderate to severe renal impairment, dosage reduced by half and given one dose every other day.

- *To treat opioid-induced constipation in patients with chronic noncancer pain*

### SUBCUTANEOUS INJECTION

**Adults.** 12 mg once daily.

### TABLETS

**Adults.** 450 mg once daily in the morning.

**DOSAGE ADJUSTMENT** For patients receiving palliative care, with moderate to severe renal failure (creatinine clearance less than 60 ml/min), dosage reduced by half for subcutaneous injection. For patients with chronic noncancer pain with moderate to severe hepatic or renal impairment taking tablet form, daily dosage reduced to 150 mg daily.

Route	Onset	Peak	Duration
SubQ	Unknown	0.5 hr	Unknown

## Mechanism of Action

Binds to peripherally acting mu-opioid receptors in the GI tract, preventing opioid-induced slowing of GI motility and transit time. When motility and transit time are restored to normal, constipation is relieved.

## Contraindications

Hypersensitivity to methylnaltrexone bromide or its components, GI obstruction

## Interactions

### DRUGS

*other opioid antaonists:* Possible additive effects and increased risk of opioid withdrawal

## Adverse Reactions

**CNS:** Anxiety, chills, dizziness, headache, malaise, tremor

**EENT:** Rhinorrhea

**ENDO:** Hot flashes

**GI:** Abdominal distention, pain, or tenderness; diarrhea; flatulence; GI cramping, **GI perforation**; nausea; vomiting

**MS:** Muscle spasms

**SKIN:** Excessive diaphoresis, piloerection

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- The use of drug during pregnancy may precipitate opioid withdrawal in a fetus due to the immature fetal blood-brain barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding should not be undertaken during drug therapy

## Nursing Considerations

- Use methylnaltrexone cautiously in patients with known or suspected lesions of the gastrointestinal (GI) tract as well as conditions that may affect the structural integrity of the GI tract wall, such as diverticular disease, infiltrative GI tract malignancies, Ogilvie's syndrome, peptic ulcer disease, and peritoneal metastases, because of increased risk of GI perforation.
- Know that food affects absorption of tablet form of drug. Give on an empty stomach only with water 30 minutes before the first meal of the day.
- To determine volume of drug to give subcutaneously to patients who weigh more than 114 kg (251 lb) or less than 38 kg (84 lb), multiply patient's weight in pounds by 0.0034 and round up to the nearest 0.1 ml. Or, multiply patient's weight in kilograms by 0.0075 and round up to the

nearest 0.1 ml. For patients who weigh 62 to 114 kg (136 to 251 lb), injection volume administered should be 0.6 ml. For patients who weigh 38 to less than 62 kg (84 to less than 136 lb), injection volume administered should be 0.4 ml.

- Inspect vial before giving drug subcutaneously to make sure solution is clear and colorless to pale yellow.
- Give parenteral form of drug only as subcutaneous injection into patient's abdomen, thigh, or upper arm and no more than once in 24 hours. Make sure to rotate injection sites.
- Once parenteral form of drug is drawn into syringe, it should be given immediately. However, if needed, it may be stored at room temperature for up to 24 hours.
- Notify prescriber about persistent or severe diarrhea, and expect drug to be discontinued. Be aware that elderly patients experience a higher incidence of diarrhea.
- Monitor patient for development of persistent, severe, or worsening abdominal pain because gastrointestinal perforation may occur with severe constipation that has not responded to methylnaltrexone therapy. Notify prescriber immediately and expect drug to be discontinued.
- Monitor patient for symptoms of opioid withdrawal such as abdominal pain, anxiety, chills, diaphoresis, diarrhea, or yawning that has occurred with methylnaltrexone therapy. Patients at greatest risk for opioid withdrawal are those who have disruptions to the blood-brain barrier with opioid administration.

## **PATIENT TEACHING**

- Instruct patient prescribed tablet form to take it on an empty stomach with water 30 minutes before the first meal of the day.
- Teach patient or caregiver how to prepare and give methylnaltrexone subcutaneously. Stress need to rotate injection sites.
- Inform patient that a bowel movement may occur within 30 minutes after drug has been administered.
- Advise patient that if abdominal pain, nausea, persistent or severe diarrhea, or vomiting that is new or worsens occurs, prescriber should be notified and drug discontinued.
- Reassure patient that drug is not a controlled substance.

- Tell patient to stop taking methylphenidate if she stops taking opioid pain medication.

## **methylphenidate hydrochloride**

**Adhansia XR, Aptensio XR, Concerta, Cotempla XR-ODT, Daytrana, Jornay PM, Metadate CD, Metadate ER, Methylin, Methylin ER, QuilliChew ER, Quillivant XR, Ritalin, Ritalin-LA, Ritalin-SR**

### **Class, Category, and Schedule**

*Pharmacologic class:* Piperidine

*Therapeutic class:* CNS stimulant

*Controlled substance schedule:* II

### **Indications and Dosages**

- *To treat attention-deficit hyperactivity disorder (ADHD)*

#### **ORAL SOLUTION, S.R. TABLETS, TABLETS (METHYLIN, RITALIN)**

**Adults** *Initial:* 10 mg twice daily or three times daily 30 to 45 min before breakfast and lunch, and a third dose

between 2 and 4 pm, if needed. Increased by 5 to 10 mg weekly, as needed. *Maximum:* 60 mg daily in two or three divided doses.

**Children age 6 and over.** *Initial:* 5 mg twice daily 30 to 45 min before breakfast and lunch; increased by 5 to 10 mg daily at 1-wk intervals. *Maximum:* 60 mg daily in two to three divided doses.

## **E.R. CAPSULES (RITALIN LA)**

**Children ages 6 to 12 years.** *Initial:* 10 or 20 mg once daily, increased weekly in increments of 10 mg, as needed. *Maximum:* 60 mg daily.

***DOSAGE ADJUSTMENT*** For children switching from Ritalin twice daily or Ritalin SR: if previous dose was 10 mg twice daily, dosage changed to 20 mg once daily; if previous dose was 15 mg twice daily, dosage changed to 30 mg once daily; if previous dose was 20 mg twice daily, dosage changed to 40 mg once daily; and if previous dose was 30 mg twice daily, dosage changed to 60 mg once daily.

## **E.R. ORAL SUSPENSION (QUILLIVANT XR)**

**Adults and children age 6 and over.** *Initially:* 20 mg once daily in morning; increased weekly in increments of 10 to 20 mg, as needed. *Maximum:* 60 mg daily.

## **SUSTAINED RELEASE TABLETS (METADATE ER, RITALIN SR)**

**Adults and children age 6 and over who are switching from immediate release to sustained release form.**

*Initial:* If dosage same as immediate release and not taken more frequently than every 8 hr, sustained release dosage same taken once daily before breakfast, increased by 10

mg weekly, as needed. *Maximum:* 60 mg once daily before breakfast.

## **E.R. ONCE-DAILY TABLETS (CONCERTA)**

**Adults age 18 to 65 years and children age 6 and over who are methylphenidate-naïve.** 18 mg daily before breakfast for children and adolescents and 18 mg to 36 mg once daily before breakfast for adults; increased in 18-mg increments at 1-wk intervals. *Maximum:* 72 mg daily (adults and children over age 12), 54 mg/day (children ages 6 to 12).

**Adults and children age 6 and over who are currently taking immediate-release methylphenidate tablets.** If previous dosage was 5 mg twice daily or three times daily, dosage switched to 18 mg once daily in morning; if previous dosage was 10 mg twice daily or three times daily, dosage switched to 36 mg once daily in morning; if previous dosage was 15 mg twice daily or three times daily, dosage switched to 54 mg in the morning; and for adults only if dosage was 20 mg twice daily or three times daily, dosage switched to 72 mg in the morning.

## **E.R. ONCE-DAILY CAPSULES (METADATE CD)**

**Adults and children age 6 and over.** *Initial:* 20 mg daily in the morning before breakfast, increased by 10 to 20 mg daily every wk, as needed. *Maximum:* 60 mg daily.

## **E.R. CAPSULES (ADHANSIA XR)**

**Adults and children age 6 and over.** *Initial:* 25 mg once daily in morning increased in increments of 10 to 15 mg at intervals of at least 5 days. *Maximum:* 85 mg daily for adults; 70 mg daily for children.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O. (tablets)	Unknown	Unknown	3–6 hr
P.O. (E.R., S.R.)	Unknown	Unknown	About 8 hr
P.O. (E.R. once daily)	Unknown	Unknown	About 12 hr

## **E.R. CAPSULES (APTENSIO XR)**

**Adults and children age 6 and over.** *Initial:* 10 mg once daily in morning, increased by 10 mg once daily weekly, as needed. *Maximum:* 60 mg once a day in the morning.

## **ORALLY DISINTEGRATING TABLET (COTEMPLA XR-ODT)**

**Children ages 6 to 17.** *Initial:* 17.3 mg once daily in the morning, then titrated weekly in increments of 8.6 mg to 17.3 mg. *Maximum:* 51.8 mg daily.

## **E.R. CHEWABLE TABLETS (QUILLICHEW ER)**

**Adults and children ages 6 and over.** *Initial:* 20 mg once daily in the morning, increased weekly in increments of 10 mg, 15 mg, or 20 mg daily, as needed. *Maximum:* 60 mg once daily in the morning.

## **E.R. CAPSULES (JORNAY PM)**

**Adults and children age 6 and over.** 20 mg once daily in evening, increased weekly in increments of 20 mg, as needed. *Maximum:* 100 mg once daily.

## **TRANSDERMAL PATCH (DAYTRANA)**

**Adults and children age 6 and over.** *Initial:* 10-mg (12.5-cm<sup>2</sup>) patch worn 9 hr daily for wk 1; 15-mg (18.75-cm<sup>2</sup>) patch worn 9 hr daily for wk 2; 20-mg (25-cm<sup>2</sup>) patch worn

9 hr daily for wk 3; 30-mg (37.5-cm<sup>2</sup>) patch worn 9 hr daily for wk 4 and thereafter. *Maximum:* 30-mg (37.5-cm<sup>2</sup>) patch worn 9 hr daily.

➤ *To treat narcolepsy*

## **ORAL SOLUTION, TABLETS (METHYLIN, RITALIN)**

**Adults.** *Initial:* 10 mg twice daily or three times daily 30 to 45 min before meals, increased by 5 to 10 mg daily every wk, as needed. *Maximum:* 60 mg daily in two or three divided doses.

**Children age 6 and over.** *Initial:* 5 mg twice daily before breakfast and lunch, increased weekly in increments of 5 to 10 mg weekly. *Maximum:* 60 mg daily in divided doses.

## **SUSTAINED RELEASE TABLETS (METADATE ER, RITALIN SR)**

**Adults who are switching from immediate release to sustained release form.** *Initial:* If dosage same as immediate release and not taken more frequently than every 8 hr, dosage same for sustained release taken once daily before breakfast, increased by 10 mg weekly, as needed. *Maximum:* 60 mg once daily before breakfast.

## **Mechanism of Action**

Blocks the reuptake mechanism of dopaminergic neurons in the cerebral cortex and subcortical structures of the brain, including the thalamus, decreasing motor restlessness, and improving concentration.

Methylphenidate also may trigger sympathomimetic activity. This action produces decreased fatigue and increased alertness and motor activity in patients with narcolepsy.

# Contraindications

*For all forms:* Agitation, marked anxiety, tension; glaucoma; hypersensitivity to methylphenidate or its components; tics or diagnosis or history of Tourette's syndrome; use within 14 days of an MAO inhibitor *For Metadate CD:* Fructose intolerance, glucose-galactose malabsorption, or sucrase-isomaltase insufficiency (Metadate CD): Hypertension and other cardiovascular conditions such as angina pectoris, cardiac arrhythmias, heart failure, and recent myocardial infarction; hyperthyroidism; thyrotoxicosis; use of halogenated anesthetics

# Interactions

## DRUGS

*angiotensin-converting enzyme (ACE inhibitors, angiotensin II receptor blockers (ARBs), beta blockers, calcium channel blockers, centrally acting alpha-2 receptor agonists, potassium-sparing and thiazide diuretics:*

Decreased effectiveness to treat hypertension

*anticonvulsants, oral anticoagulants, phenylbutazone, tricyclic antidepressants:* Inhibited metabolism and increased blood levels of these drugs

*buspirone, fentanyl, lithium, MAO inhibitors, selective serotonin reuptake inhibitors, serotonin-norepinephrine reuptake inhibitors, St. John's wort, tricyclic*

*antidepressants, triptans, tryptophan:* Increased risk of serotonin syndrome

*halogenated anesthetics:* Possibly sudden decrease in blood pressure during surgery

*MAO inhibitors:* Possibly increased adverse effects of methylphenidate, possibly severe hypertension

## FOODS

*caffeine*: Increased methylphenidate effects

## ACTIVITIES

*alcohol use*: Possibly increased CNS effects; with long-acting forms, possible increased adverse effects

## Adverse Reactions

**CNS:** Aggressiveness, agitation, anger, anxiety, cerebral arteritis, **cerebral occlusion**, confusion, **CVA**, depression, disorientation, dizziness, drowsiness, dyskinesia, emotional lability, excessive talkativeness, fatigue, fever, hallucinations, headache, hyperactivity, hypomania, insomnia, irritability, ischemic neurologic defects (reversible), lability of affect, lethargy, mania, migraine, motor tics, nervousness, **neuroleptic malignant syndrome**, obsessive-compulsive disorder (rare), paresthesia, psychosis, restlessness, sedation, **seizures**, somnolence, stroke, **suicidal ideation**, transient mood depression, tension, tremor, Tourette's syndrome (rare), toxic psychosis, vertigo

**CV:** Angina, **arrhythmias**, **bradycardia**, **cardiac arrest**, chest discomfort or pain, **extrasystoles**, hypertension, **hypotension**, **MI**, necrotizing vasculitis, palpitations, peripheral vasculopathy including Raynaud's phenomenon, **sudden death**, **supraventricular tachycardia**, tachycardia, vasculitis

**EENT:** Accommodation abnormality, blurred vision, diplopia, dry mouth or throat, mydriasis, nasopharyngitis, pharyngitis, rhinitis, sinusitis, vision changes

**ENDO:** Dysmenorrhea, growth suppression in children with long-term use, gynecomastia

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated bilirubin and liver enzymes, **hepatotoxicity**, nausea, **severe hepatic failure or injury**, vomiting

**GU:** Decreased libido, hematuria, priapism

**HEME:** Anemia, **decreased platelet count**, **leukopenia**, **pancytopenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**MS:** Arthralgia, myalgia, muscle tightness or twitching, **rhabdomyolysis**

**RESP:** Cough, dyspnea, upper respiratory tract infection

**SKIN:** Allergic contact dermatitis, alopecia, application-site reactions (transdermal patch), bullous skin conditions, chemical leukoderma (persistent loss of skin pigmentation with transdermal patch), excessive diaphoresis, erythema, **erythema multiforme**, exanthemas, **exfoliative dermatitis**, fixed drug eruption, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, elevated alkaline phosphatase, physical and psychological dependence, weight loss (prolonged use)

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <https://womensmentalhealth.org/adhd-medications/>.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Be aware that methylphenidate may induce CNS stimulation and psychosis and may worsen behavior disturbances and thought disorders in patients who already have psychosis. Use drug cautiously in patients with psychosis.

- Keep in mind that, when signs and symptoms of ADHD occur with acute stress reactions or with preexisting structural cardiac abnormalities or other serious heart problems, methylphenidate usually isn't indicated because of possible worsened reaction or sudden death.
- Reconstitute oral suspension form by first tapping bottle until powder flows freely. Remove bottle cap and add specified amount of water to the drug bottle (53 ml of water to 300-mg drug bottle, 105 ml of water to 600-mg drug bottle, 131 ml of water to 750-mg drug bottle, or 158 ml of water to 900-mg drug bottle). Insert bottle adapter into neck of bottle and replace cap. Shake vigorously using a back and forth motion for at least 10 seconds. Know that reconstituted oral suspension is stable up to 4 months.
- Monitor children and adolescents for first-time psychotic or manic symptoms. If present, notify prescriber and expect drug to be discontinued.

**WARNING** Know that the E.R. tablet form (Concerta) shouldn't be given to patients with esophageal motility disorders; drug may cause GI obstruction because tablet doesn't change shape in GI tract.

- Monitor blood pressure and pulse rate to detect hypertension and excessive stimulation. Notify prescriber if present. For patient with hypertension, expect to increase antihypertensive dosage or add another antihypertensive to regimen.

**WARNING** Watch for signs of physical or psychological dependence. Methylphenidate's abuse potential is

similar to that of amphetamines; use cautiously in patients with a history of drug abuse.

- Stopping drug abruptly after long-term use may unmask dysphoria, paranoia, severe depression, or suicidal thoughts.
- Monitor growth in children. Report failure to grow or gain weight, and expect to stop drug.
- Watch closely (especially children, adolescents, and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor transdermal patch application site for erythema. If more intense reactions occur with erythema, such as local edema or papule or vesicle formation that doesn't improve within 48 hours after patch is removed from irritated site or that spreads beyond the patch site, further diagnostic testing is required to determine presence of allergic contact dermatitis.
- Know that patients with allergic contact dermatitis from transdermal patch may develop systemic allergy reaction if methylphenidate is taken by another route, such as by mouth. Monitor patient closely if route of administration changes, and report any evidence of flare-up of previous dermatitis or positive patch-test sites, generalized skin eruptions in previously unaffected skin, or other symptoms such as arthralgia, diarrhea, fever, headache, malaise, or vomiting because drug may need to be discontinued.
- Observe patient for paradoxical aggravation of symptoms or other serious adverse reactions. If present, notify prescriber and expect dosage to be reduced or drug discontinued.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of methylphenidate when taken in combination with serotonergic drugs. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. If symptoms occur, notify prescriber immediately, expect drug to be discontinued, and provide supportive care.

- Inspect patient's fingers and toes for signs of peripheral vasculopathy, such as digital ulceration and/or soft tissue breakdown. Although usually mild and intermittent, more severe manifestation may occur. Notify prescriber if present, and expect dose to be reduced or drug discontinued.

## **PATIENT TEACHING**

- Warn patient that methylphenidate is a controlled substance and can be abused and lead to dependence. Dosage should not be increased or dosage interval shortened without prescriber knowledge.
- For transdermal form, teach patient to apply patch to a clean, dry location in his hip area 2 hours before effect is needed and to remove it 9 hours after application.
- Caution patient to avoid applying patch to skin that's damaged, irritated, or oily and to avoid the waistline, where clothing may dislodge the patch. Tell patient to rotate application sites between hips.
- Instruct patient to apply patch immediately after opening pouch and removing protective liner. Tell him to press patch firmly in place with palm of his hand for about 30 seconds. Reassure patient that exposing site to water shouldn't cause patch to fall off. If a patch does fall off, explain that a new patch may be applied but that the total exposure time for the day shouldn't exceed 9 hours.
- Urge patient not to chew or crush E.R. tablets.
- Tell patient to take tablets at least 6 hours before bedtime to avoid insomnia and to take E.R. once-daily tablets in the morning.
- Advise patient taking E.R. once-daily tablets (Concerta) that he may see intact tablet in stool. Explain that drug is slowly released from nonabsorbable tablet shell.
- Tell patient taking capsule form to swallow it whole or sprinkle contents onto a tablespoon of applesauce and take immediately, followed by a liquid such as water.
- Instruct patient taking E.R. capsules (Jornay PM brand) to take drug only in the evening, starting at 8:00 pm, with timing adjustment of between 6:30 pm and 9:30 pm, as needed. Stress importance of not taking this form of drug in the morning.
- Instruct patient taking E.R. oral suspension form to vigorously shake the bottle for at least 10 seconds before measuring dose to ensure that the proper dose is being taken. If using the oral dosing dispenser, tell patient to remove the bottle cap and confirm that the bottle adapter has been

inserted into the top of the bottle. Tell him to insert the tip of the oral dosing dispenser provided into the bottle adapter, turn bottle upside down, and withdraw prescribed amount of liquid into the oral dosing dispenser. Then have patient remove the filled oral dosing dispenser from bottle and dispense drug directly into his mouth. Tell him to then replace the bottle cap and wash the oral dosing dispenser after each use (components are dishwasher-safe). Also alert patient taking drug long term that prescriber may take patient off of drug periodically to determine continued need.

- Tell patient taking ODT tablet not to remove the tablet from the blister pack until just prior to dosing and to take the tablet immediately after opening the blister pack. Tell him to use dry hands when opening the blister pack and remove tablet by peeling back the foil on the blister pack. Caution him not to push the tablet through the foil. Tell patient to place the whole tablet on his tongue and allow it to disintegrate without chewing or crushing it. Inform patient that no liquid is needed to take the tablet.

**WARNING** Urge patient to seek immediate emergency attention if symptoms of a heart attack or stroke occur. Also teach patient how to take a blood pressure and pulse and to monitor both regularly

- Direct patient to notify prescriber about excessive nervousness, fever, insomnia, palpitations, rash, or vomiting.
- Instruct patient to tell all prescribers about methylphenidate therapy, as serious drug interactions can occur. Stress importance of seeking immediate medical care if persistent, severe, or unusual adverse reactions occur.
- Warn patient with seizure disorder that drug may cause seizures.
- Inform parents of children on long-term therapy that drug may delay growth.
- Warn male patients and parents of male children that painful or prolonged penile erections may occur while taking the drug, especially after a dosage increase or during period of drug withdrawal. In the event that this happens, immediate medical attention should be sought.
- Instruct patient or parents to monitor fingers and toes for ulceration and/or soft tissue breakdown. If noticed, prescriber should be called. Reassure patient that signs and symptoms generally improve after the dose is reduced or drug is discontinued.

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.
- Alert patient prescribed transdermal patch that a persistent loss of skin pigmentation, most commonly at and around the application site, may occur. Tell patient to notify prescriber if this occurs and expect this form of methylphenidate to be discontinued.
- Alert patient and caregiver that psychotic or manic symptoms, even without a prior history, may occur and should be reported to prescriber.
- Advise patient to avoid alcohol while taking methylphenidate.

**methylprednisolone**

**Medrol**

**methylprednisolone acetate**

**Depo-Medrol**

**methylprednisolone sodium succinate**

**Solu-Medrol**

## **Class and Category**

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Corticosteroid

## **Indications and Dosages**

- *To treat immune and inflammatory disorders*

## **TABLETS (METHYLPREDNISOLONE)**

**Adults.** 4 to 48 mg daily as a single dose or in divided doses. Alternatively, twice the daily dose every other day.

**Children.** 0.11 to 1.66 mg/kg daily in divided doses three times daily or four times daily.

## **I.V. INFUSION, I.M. INJECTION, I.V. INJECTION (METHYLPREDNISOLONE SODIUM SUCCINATE)**

**Adults. Initial:** 10 to 40 mg with subsequent doses dictated by patient's response and condition being treated. I.V. injection given over several min but doses greater than 0.5 g must be given over at least 10 min. I.V. infusion given over several min but when dose has reached 30 mg/kg, infusion given over at least 30 min.

## **I.M. INJECTION (METHYLPREDNISOLONE ACETATE)**

**Adults. Initial:** 4 to 120 mg daily according to clinical response.

## **INTRA-ARTICULAR, INTRALESIONAL, OR SOFT-TISSUE INJECTION (METHYLPREDNISOLONE ACETATE)**

**Adults.** 4 to 10 mg for small joints; 10 to 40 mg for medium joints; and 20 to 80 mg for large joints every 1 to 5 wk, according to clinical response.

- *To treat acute exacerbations of multiple sclerosis*

## **TABLETS (METHYLPREDNISOLONE)**

**Adults.** 200 mg daily for 7 days followed by 80 mg every other day for 1 mo.

## **I.V. OR I.M. INJECTION (METHYLPREDNISOLONE ACETATE)**

**Adults.** 160 mg daily for 1 wk followed by 64 mg every other day for 1 mo. I.V. injection given over at least 1 min.

## **I.V. INFUSION (METHYLPREDNISOLONE SODIUM SUCCINATE)**

Adults. 500 to 1,000 mg daily as a single dose or in divided doses for 3 to 5 days infused over at least 30 min

Route	Onset	Peak	Duration
P.O.	In 60 min	1-2 hr	1.25-1.5 days
I.V.	Rapid	30 min	Unknown
I.M.	6-48 hr	4-8 days	1-4 wk

## **Mechanism of Action**

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by inhibiting accumulation of monocytes and neutrophils at inflammation sites, stabilizing lysosomal membranes, suppressing the antigen response of macrophages and helper T cells, and inhibiting the synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

## **Incompatibilities**

Don't mix methylprednisolone with any drug without first consulting pharmacist. Don't dilute methylprednisolone

acetate with any other drug.

## Contraindications

Hypersensitivity to cow's milk or other dairy products for Solu-Medrol 40-mg formulation, hypersensitivity to methylprednisolone or its components, idiopathic thrombocytopenic purpura (I.M.), intrathecal administration, premature infants (preparations containing benzyl alcohol), systemic fungal infections

## Interactions

### DRUGS

*aminoglutethimide*: Possibly loss of methylprednisolone-induced adrenal suppression

*amphotericin B, potassium-depleting diuretics*: Possibly severe hypokalemia

*anticholinesterases*: Possibly severe weakness in patients with myasthenia gravis

*aspirin, NSAIDs*: Increased risk of adverse GI effects and bleeding

*barbiturates, carbamazepine, phenytoin, rifampin*: Decreased blood methylprednisolone level

*cholestyramine*: Possibly increased methylprednisolone clearance

*cyclosporine*: Increased activity of both drugs

*digoxin*: Possibly hypokalemia-induced arrhythmias and digitalis toxicity

*estrogens, oral contraceptives*: Possibly increased therapeutic and toxic effects of methylprednisolone

*insulin, oral antidiabetic drugs*: Possibly increased blood glucose level

*isoniazid*: Possibly decreased therapeutic effects of isoniazid

*ketoconazole, macrolide antibiotics such as erythromycin and troleandomycin*: Decreased methylprednisolone clearance and increased risk of adverse effects

*oral anticoagulants, thrombolytics*: Increased risk of decreased therapeutic effects of these drugs

*vaccines*: Decreased antibody response and increased risk of neurologic complications

## ACTIVITIES

*alcohol use*: Increased risk of adverse GI effects including bleeding

## Adverse Reactions

**CNS**: Ataxia, behavioral changes, depression, dizziness, euphoria, fatigue, headache, **increased intracranial pressure with papilledema**, insomnia, malaise, mood changes, neuropathy, paresthesia, restlessness, **seizures**, steroid psychosis, syncope, vertigo

**CV**: **Arrhythmias**, **cardiac arrest**, edema, **fat embolism**, **heart failure**, hypertension, **hypertrophic cardiomyopathy** (premature infants), **hypotension**, **myocardial rupture following recent MI**, tachycardia, **thromboembolism**, thrombophlebitis

**EENT**: Exophthalmos, glaucoma, increased intraocular pressure, nystagmus, posterior subcapsular cataracts

**ENDO**: **Adrenal insufficiency**, cushingoid symptoms (buffalo hump, central obesity, moon face, supraclavicular fat pad enlargement), diabetes mellitus, growth suppression in children, hyperglycemia

**GI**: Abdominal distention, **acute hepatitis**, elevated liver enzymes, hepatomegaly, hiccups, increased appetite,

**melen**, nausea, **pancreatitis**, peptic ulcer, ulcerative esophagitis, vomiting

**GU:** Amenorrhea, glycosuria, menstrual irregularities, perineal burning or tingling

**HEME:** Easy bruising, leukocytosis

**MS:** Arthralgia; aseptic necrosis of femoral and humeral heads; Charcot-like arthropathy; compression fractures; muscle atrophy, twitching, or weakness; myalgia; osteoporosis; spontaneous fractures; steroid myopathy; tendon rupture

**RESP:** **Pulmonary edema**

**SKIN:** Acne; allergic dermatitis; altered skin pigmentation; diaphoresis; dry, scaly skin; erythema; hirsutism; necrotizing vasculitis; petechiae; purpura; rash; scarring; sterile abscess; striae; subcutaneous fat atrophy; thin, fragile skin; urticaria

**Other:** Activation of latent infections, **anaphylaxis**, **angioedema**, exacerbation of systemic fungal infections, **hypernatremia**, **hypocalcemia**, **hypokalemia**, **hypokalemic alkalosis**, impaired wound healing, masking of signs of infection, **metabolic alkalosis**, negative nitrogen balance from protein catabolism, suppressed skin test reaction, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm. Some formulations contain benzyl alcohol, which can cross the placental barrier and cause “gasping syndrome” in premature infants when born.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- Infants born to mothers who have received corticosteroids during pregnancy should be observed for hypoadrenalism.

## LACTATION

- Drug appears in breast milk and could suppress growth, interfere with endogenous corticosteroid production, or cause other adverse effects if infant is breastfed.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that high doses of systemic corticosteroids, including methylprednisolone, should not be used for the treatment of traumatic brain injury because of increased risk of death or in patients with active ocular herpes simplex because of risk of corneal perforation. Preparations containing benzyl alcohol should not be used to treat pediatric patients because of risk of "gasping syndrome."
- Administer methylprednisolone with extreme caution in patients with a recent myocardial infarction because corticosteroid use may increase risk of left ventricular free wall rupture.
- Use cautiously in patients with congestive heart failure or renal insufficiency because sodium retention and edema can occur in patients taking a corticosteroid. Also use cautiously in patients with diverticulitis, fresh intestinal anastomoses, nonspecific ulcerative colitis, or peptic ulcer; these conditions increase risk of perforation during corticosteroid therapy. In addition, use caution in patients with systemic sclerosis, because drug may increase risk of scleroderma renal crisis.
- Give methylprednisolone tablets with food to minimize GI irritation and indigestion. For once-daily dosing, give in the morning to coincide with normal cortisol secretion. Expect prescriber to add an antacid or H<sub>2</sub>-receptor antagonist to regimen.
- Discard parenteral products that are discolored or contain particles. Discard any remaining Depo-Medrol suspension after prescribed dose is drawn from vial.
- Inject I.M. form deep into gluteal muscle. Avoid injecting into deltoid muscle because of risk of subcutaneous atrophy.
- Arrange for low-sodium diet with added potassium, as prescribed.
- Protect patient from falling, especially elderly patient at risk for fractures from osteoporosis.

- Closely monitor patient for signs of infection because drug may mask them or may worsen systemic fungal infections or active latent disease. Be aware that chickenpox and measles can become life-threatening in patients taking a corticosteroid.
- Assess for possible depression or psychotic episodes during therapy.
- Monitor blood glucose level; dosage of insulin or oral antidiabetic drug may need to be adjusted in diabetic patient.

**WARNING** To avoid possibly fatal acute adrenocortical insufficiency, expect to taper long-term therapy when discontinuing it, but expect dosage to be increased during times of stress.

- Be aware that changes in thyroid function, such as development of hyperthyroidism or hypothyroidism, may require dosage adjustment in chronic therapy because metabolic clearance of methylprednisolone is affected by thyroid activity.
- Know that skin testing should be avoided during methylprednisolone therapy because drug may suppress reaction.
- Monitor patient's liver enzymes, as ordered, especially in patients receiving high doses such as 1 g/day intravenously (usually for treatment of exacerbations of multiple sclerosis). This is important because, although rare, this can develop into a toxic form of acute hepatitis. The onset of liver dysfunction can occur several weeks or even longer after administration of methylprednisolone. Notify prescriber if liver dysfunction is suspected and expect drug to be discontinued, as condition can develop into acute liver failure and death.

## **PATIENT TEACHING**

- Caution patient not to stop taking methylprednisolone abruptly or to change dosage without consulting prescriber.
- Tell patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Caution against double-dosing.
- Urge patient to notify prescriber immediately about dark or tarry stools; signs of impending adrenocortical insufficiency, such as anorexia, dizziness, fainting, fatigue, fever, joint pain, muscle weakness, or nausea; and swelling or sudden weight gain.

- Instruct patient not to obtain vaccinations unless approved by prescriber.
- Urge patient to take calcium supplements, vitamin D, or both if recommended by prescriber.
- Inform patient that insomnia and restlessness usually resolve after 1 to 3 weeks.
- Caution patient to avoid people with contagious diseases.
- Explain the need for regular exercise or physical therapy to maintain muscle mass.
- Advise patient to carry medical identification that documents his need for long-term corticosteroid therapy.

## metoclopramide hydrochloride

**Metozolv ODT, Reglan**

### Class and Category

*Pharmacologic class:* Dopamine-2 receptor antagonist

*Therapeutic class:* Antiemetic, upper GI stimulant

### Indications and Dosages

➤ *To treat diabetic gastroparesis*

#### **ODT TABLETS, ORAL SOLUTION, ORAL SOLUTION CONCENTRATE, TABLETS**

**Adults experiencing mild symptoms.** 10 mg 30 min before meals and at bedtime four times daily for 2 to 8 wk.

*Maximum:* 40 mg daily in divided doses.

## **I.V. OR I.M. INJECTION**

**Adults experiencing severe symptoms.** 10 mg 30 min before meals and at bedtime. I.V. injection given slowly over 1 to 2 min for up to 10 days before being switched to oral formulation and continued for another 2 to 8 wk.

➤ *To treat gastroesophageal reflux disease*

## **OTD TABLETS, ORAL SOLUTION, ORAL SOLUTION CONCENTRATE, TABLETS**

**Adults. Continuous dosing:** 10 to 15 mg 30 min before meals and at bedtime for 4 to 12 wk.

*Intermittent dosing:* 20 mg as a single dose prior to provoking situation. *Maximum:* 60 mg daily in divided doses.

## **ODT TABLETS**

**Adults.** 10 to 15 mg up to four times daily at least 30 min before eating and at bedtime for 4 to 12 weeks.

***DOSAGE ADJUSTMENT*** For patients with diabetic gastroparesis or gastroesophageal reflux disease who are taking tablet form (not ODT) and are elderly, dosage reduced to 5 mg four times daily; patients who are CYP2D6 poor metabolizers or have moderate to severe hepatic or renal impairment or are taking strong CYP2D6 inhibitors such as bupropion, fluoxetine, paroxetine, or quinidine, dosage reduced to 5 mg four times daily or 10 mg three times daily; and for patients with end-stage renal disease, including those treated with continuous ambulatory peritoneal dialysis or hemodialysis, dosage reduced to 5 mg four times daily or 10 mg twice daily. For patients who are

taking ODT tablets or oral solution and have a creatinine clearance of less than 40 ml/min, dosage reduced by 50%.

- *To prevent or reduce nausea and vomiting from emetogenic cancer chemotherapy*

## **I.V. INFUSION**

**Adults receiving less emetogenic regimens.** 1 mg/kg infused over at least 15 min 30 min before chemotherapy and repeated every 2 hr for 2 additional doses, then every 3 hr for 3 doses.

**Adults receiving highly emetogenic regimens with drugs such as cisplatin or dacarbazine.** 2 mg/kg infused over at least 15 min 30 min before chemotherapy and repeated every 2 hr for 2 additional doses, then every 3 hr for 3 doses.

- *To prevent postoperative nausea and vomiting*

## **I. M. INJECTION**

**Adults.** 10 to 20 mg given at or near end of surgery.

- *To facilitate small bowel intubation; to aid in radiological examinations*

## **I.V. INJECTION**

**Adults and adolescents over age 14.** 10 mg undiluted given slowly over 1 to 2 min.

**Children ages 6 to 14 years.** 2.5 to 5 mg undiluted given slowly over 1 to 2 min.

**Children under 6 years.** 0.1 mg/kg undiluted given slowly over 1 to 2 min.

***DOSAGE ADJUSTMENT*** Parenteral dosages given for any condition, reduced by half if creatinine clearance is less than 40 ml/min.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	30-60 min	Unknown	1-2 hr
I.V.	1-3 min	Unknown	1-2 hr
I.M.	10-15 min	Unknown	1-2 hr

## **Mechanism of Action**

Antagonizes the inhibitory effect of dopamine on GI smooth muscle. This causes gastric contraction, which promotes gastric emptying and peristalsis, thus reducing gastroesophageal reflux. Metoclopramide also blocks dopaminergic receptors in the chemoreceptor trigger zone, preventing nausea and vomiting.

## **Incompatibilities**

Don't administer metoclopramide through same I.V. line as calcium gluconate, cephalothin sodium, chloramphenicol sodium, cisplatin, erythromycin lactobionate, furosemide, methotrexate, penicillin G potassium, or sodium bicarbonate.

## **Contraindications**

Catecholamine-releasing paragangliomas, epilepsy, history of dystonic reaction or tardive dyskinesia to metoclopramide, hypersensitivity to metoclopramide or its components, pheochromocytoma, when stimulation of gastrointestinal motility might be dangerous such as in the presence of gastrointestinal hemorrhage, mechanical obstruction, or perforation

## **Interactions**

## DRUGS

*anticholinergics, antidiarrheals, antiperistaltics, opioid analgesics*: Decreased absorption of metoclopramide, thus decreasing effectiveness

*antipsychotic drugs*: Potential for additive effects, including increased frequency and severity of neuroleptic malignant syndrome, other extrapyramidal symptoms, and tardive dyskinesia

*CNS depressants such as anxiolytics, hypnotics, opiates, sedatives*: Increased risk of CNS depression

*apomorphine, bromocriptine, cabergoline, levodopa, pramipexole, ropinirole, rotigotine*: Decreased effectiveness of metoclopramide; potential for exacerbation of symptoms such as Parkinsonian symptoms

*atovaquone, cimetidine, digoxin, posaconazole (oral suspension)*: Decreased absorption and reduced effectiveness of these drugs

*CNS depressants*: Possibly increased CNS depression

*cyclosporine, sirolimus, tacrolimus*: Increased absorption and risk of adverse effects

*CYP2D6 inhibitors (strong) such as bupropion, fluoxetine, paroxetine, quinidine*: Increased plasma concentrations of metoclopramide; risk of exacerbation of extrapyramidal symptoms

*MAO inhibitors*: Increased risk of severe hypertension

*mivacurium, succinylcholine*: Enhanced neuromuscular blockade

*serotonergic drugs*: Possible development of serotonin syndrome

## ACTIVITIES

*alcohol use*: Risk of increased CNS depression

# Adverse Reactions

**CNS:** Agitation, anxiety, confusion, depression, dizziness, drowsiness, extrapyramidal reactions (motor restlessness, Parkinsonism, tardive dyskinesia), fatigue, hallucinations, headache, insomnia, irritability, lassitude, nervousness, **neuroleptic malignant syndrome**, panic reaction, restlessness, **seizures**, **suicidal ideation**

**CV:** **AV block**, **bradycardia**, fluid retention, **heart failure**, hypertension, **hypotension**, **supraventricular tachycardia**

**EENT:** Dry mouth, glossal edema, **laryngeal edema**, visual disturbances

**ENDO:** Galactorrhea, gynecomastia, hyperprolactinemia

**GI:** Constipation, diarrhea, nausea

**GU:** Impotence, menstrual irregularities, urinary frequency or incontinence

**HEME:** **Agranulocytosis**, **leukopenia**, **methemoglobinemia**, **neutropenia**, **sulfhemoglobinemia**

**RESP:** **Bronchospasm**

**SKIN:** Rash, urticaria

**Other:** **Angioedema**, porphyria, restless leg syndrome

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug crosses the placental barrier and may cause extrapyramidal signs and methemoglobinemia in the neonate if given to mother during delivery.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk and may cause gastrointestinal adverse effects in the breastfed infant such as intestinal discomfort and increased intestinal gas formation as well as extrapyramidal signs (dystonias) and methemoglobinemia.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that orally disintegrating tablets are not recommended for use in children because of increased risk of tardive dyskinesia and other extrapyramidal symptoms.
- Be aware that metoclopramide therapy should not be used in patients with depression because of increased risk of suicidal ideation. Also know that drug should not be given to patients with a history of hypertension or patients taking monoamine oxidase inhibitors, because of increased risk of hypertension that could lead to a hypertensive crisis.
- Use metoclopramide cautiously in patients with hypertension because it may increase catecholamine levels. Monitor blood pressure throughout therapy. Expect drug to be discontinued in any patient with a rapid rise in blood pressure.

**WARNING** Watch closely for tardive dyskinesia, especially in the elderly, women, and patients with diabetes, because this serious adverse effect is often irreversible even after therapy stops. Therapy lasting longer than 12 weeks isn't recommended because risk of tardive dyskinesia increases the longer the patient takes metoclopramide. Risk also has been linked to total cumulative dose so prescriber must take this into account when setting dosage. Also be aware that drug

can cause other extrapyramidal symptoms besides tardive dyskinesia. For example, though rare, drug may cause dystonic reactions such as dyspnea and stridor, possibly caused by laryngospasm. At first sign of involuntary movements of face, tongue, or limbs, or any other abnormal sign or symptom, notify prescriber and expect to discontinue drug.

- Monitor patient with NADH-cytochrome b5 reductase deficiency because metoclopramide increases risk of methemoglobinemia and sulfhemoglobinemia. For patients with glucose-6-phosphate dehydrogenase (G6PD) deficiency, methylene blue treatment is not recommended if metoclopramide induced methemoglobinemia occurs because the treatment may cause hemolytic anemia in these patients, which may be fatal.
- Assess patient for signs of intestinal obstruction, such as abnormal bowel sounds, diarrhea, nausea, and vomiting, before administering metoclopramide. Notify prescriber if you detect them.
- For I.V. use, do not dilute doses of 10 mg or less. Give drug over 1 to 2 minutes. For doses larger than 10 mg, dilute in 50 ml normal saline solution, half-normal (0.45) saline solution, D<sub>5</sub>W, or lactated Ringer's solution and infuse over at least 15 minutes.
- Avoid rapid I.V. delivery because it may cause anxiety, restlessness, and drowsiness.

**WARNING** Notify prescriber if patient shows signs of toxicity, such as disorientation, drowsiness, and extrapyramidal reactions.

- Monitor patient, especially one with heart failure or cirrhosis, for possible fluid retention or volume overload due to transient increase in plasma aldosterone level. Expect metoclopramide to be discontinued if fluid retention occurs.

**WARNING** Monitor patient closely for neuroleptic malignant syndrome, a rare but potentially fatal disorder characterized by hyperthermia, muscle rigidity, altered level of consciousness, irregular pulse or blood

pressure, tachycardia, diaphoresis, and arrhythmias. Know that risk increases in patients experiencing a toxic reaction to metoclopramide as a result of overdose or receiving concomitant treatment with another drug associated with neuroleptic malignant syndrome. Expect metoclopramide to be discontinued immediately, if present.

- Store drug in a light-resistant container; discard if discolored or contains particulate.
- Monitor patient for abnormal behaviors or thoughts suggestive of suicidal ideation because depression may occur while taking metoclopramide even in patients without a history of depression.

## **PATIENT TEACHING**

- Instruct patient on how to take the form of metoclopramide prescribed.
- Advise against activities that require alertness.
- Urge patient to avoid alcohol and CNS depressants while taking metoclopramide. They may increase CNS depression.
- Tell patient to immediately report involuntary movements of face, eyes, tongue, or hands, including lip smacking, chewing, puckering of mouth, frowning, scowling, sticking out tongue, blinking, moving eyes, or shaking arms and legs.
- Explain that stopping metoclopramide may cause withdrawal symptoms that include dizziness, nervousness, and headache.
- Warn patient's family or caregiver to monitor patient for abnormal behavior or thoughts that may be suggestive of suicidal ideation. If concerns are raised, urge them to contact prescriber.
- Urge patient to tell all prescribers about metoclopramide therapy.
- Stress importance of reporting signs and symptoms that are persistent, severe, or unusual.

# metolazone

**Zaroxolyn**

## Class and Category

*Pharmacologic class:* Thiazide-like diuretic

*Therapeutic class:* Diuretic

## Indications and Dosages

➤ *To manage mild to moderate hypertension*

### **TABLETS**

**Adults.** 2.5 to 5 mg daily.

➤ *To manage edema from heart failure or renal disease*

### **TABLETS**

**Adults.** 5 to 10 mg daily for edema of heart failure; 5 to 20 mg daily for edema of renal disease.

Route	Onset	Peak	Duration
P.O.	1 hr	2 hr	12-24 hr

## Mechanism of Action

Promotes renal excretion of sodium and water by inhibiting their reabsorption in distal convoluted tubules. The resulting reduction in extracellular fluid volume and plasma reduces blood pressure. Metolazone also helps reduce

blood pressure by decreasing peripheral vascular resistance.

## **Contraindications**

Anuria, hepatic coma or precoma, hypersensitivity to metolazone or its components

## **Interactions**

### **DRUGS**

*ACTH or corticosteroids:* Possible increased risk of hypokalemia and salt and water retention

*antigout drugs:* Increased blood uric acid level and risk of gout attack

*barbiturates, narcotics, other antihypertensives:* Increased risk of orthostatic hypotension

*digoxin:* Increased risk of electrolyte imbalances and digoxin-induced arrhythmias

*diuretics:* Additive effects of both drugs, possibly leading to electrolyte imbalances and severe hypovolemia

*hydralazine:* Possibly interference with the natriuretic action of metolazone

*insulin, oral antidiabetic drugs:* Decreased effectiveness of these drugs, increased risk of hyperglycemia

*lithium:* Increased risk of lithium toxicity

*neuromuscular blockers:* Increased risk of hypokalemia and neuromuscular blockade, increased risk of respiratory depression

*NSAIDs, sympathomimetics:* Possibly decreased metolazone effectiveness

### **ACTIVITIES**

*alcohol use:* Increased risk of orthostatic hypotension

# Adverse Reactions

**CNS:** Anxiety, chills, depression, dizziness, drowsiness, headache, insomnia, neuropathy, paresthesia, restlessness, syncope, weakness

**CV:** Chest pain, cold extremities, orthostatic hypotension, palpitations, peripheral edema, vasculitis, **venous thrombosis**

**EENT:** Bitter taste, blurred vision, dry mouth, epistaxis, pharyngitis, sinus congestion, tinnitus

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, anorexia, cholecystitis, constipation, diarrhea, **hepatic dysfunction**, **hepatitis**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Decreased libido, glycosuria, impotence

**HEME:** **Agranulocytosis**, **aplastic anemia**, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, gout, myalgia

**RESP:** Cough

**SKIN:** Dry skin, necrosis, petechiae, photosensitivity, pruritus, rash, urticaria

**Other:** Hypochloremia, **hypokalemia**, **hyponatremia**, hypovolemia, **metabolic alkalosis**

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm such as fetal or neonatal jaundice, thrombocytopenia, and possibly other adverse reactions, which have occurred in adults.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## **Nursing Considerations**

- Anticipate giving metolazone with a loop diuretic if patient responds poorly to loop diuretic alone.
- Measure patient's fluid intake and output and daily weight to monitor drug's diuretic effect.
- Monitor blood chemistry test results and assess for evidence of hypochloremia, hypokalemia, and, possibly, mild metabolic alkalosis.
- Monitor serum calcium and uric acid levels, especially if patient has a history of gout or renal calculi. Metolazone may slightly increase calcium reabsorption and decrease uric acid excretion.

## **PATIENT TEACHING**

- Inform patient that metolazone controls but doesn't cure hypertension. Discuss possible need for lifelong therapy and consequences of uncontrolled hypertension.
- Instruct patient to take drug at the same time each day.
- Direct patient to take drug with food or milk to minimize adverse GI reactions.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to notify prescriber about persistent, severe diarrhea, nausea, or vomiting, which can cause dehydration and orthostatic hypotension.
- Emphasize the importance of diet control, especially limiting sodium intake, and maintaining a normal weight.
- Inform diabetic patient that metolazone may increase blood glucose level and that he should check his level often.

# metoprolol succinate

**Kaspargo Sprinkle, Toprol-XL**

# metoprolol tartrate

**Lopresor (CAN), Lopresor SR (CAN),  
Lopressor**

## Class and Category

*Pharmacologic class:* Beta<sub>1</sub>-adrenergic blocker

*Therapeutic class:* Antianginal, antihypertensive

## Indications and Dosages

- *To manage hypertension, alone or with other antihypertensives*

### **E.R. CAPSULES (KAPSPARGO SPRINKLE), E.R. TABLETS (TOPROL-XL)**

**Adults.** *Initial:* 25 to 100 mg daily, adjusted weekly as prescribed. *Usual:* 50 to 100 mg daily. *Maximum:* 400 mg daily.

**Children 6 years and over.** *Initial:* 1 mg/kg daily, not to exceed 50 mg daily with initial dose, adjusted weekly as prescribed. *Maximum:* 2 mg/kg daily, not to exceed 200 mg daily.

### **TABLETS (LOPRESSOR)**

**Adults.** *Initial:* 100 mg daily as a single dose or in 2 divided doses, adjusted weekly as prescribed. *Maximum:* 450 mg daily as a single dose or in divided doses.

**Children age 6 and over.** 1 to 2 mg/kg/day given in 2 divided doses. *Maximum:* 6 mg/kg/day or 200 mg/day.

- *To provide early treatment of acute MI or evolving acute MI*

## **TABLETS (LOPRESSOR), I.V. INJECTION (LOPRESSOR)**

**Adults.** *Initial:* 5 mg by I.V. bolus every 2 min for three doses followed by 25 to 50 mg P.O. every 6 hr for 48 hr, starting 15 min after final I.V. dose; after 48 hr, 100 mg P.O. twice daily. *Maintenance:* 100 mg P.O. twice daily for at least 3 mo.

- *To treat angina pectoris and chronic stable angina*

## **E.R. CAPSULES (KAPSPARGO SPRINKLE), E.R. TABLETS (TOPPROL-XL)**

**Adults.** 100 mg daily, increased weekly as prescribed. *Maximum:* 400 mg daily.

## **TABLETS (LOPRESSOR)**

**Adults.** *Initial:* 50 mg twice daily, adjusted weekly as prescribed. *Maximum:* 400 mg daily.

- *To treat stable, symptomatic (New York Heart Association [NYHA] class II or III), ischemic, hypertensive, or cardiomyopathic heart failure*

## **E.R. CAPSULES (KAPSPARGO SPRINKLE), E.R. TABLETS (TOPROL XL)**

**Adults.** *Initial:* 25 mg daily or 12.5 mg daily for more severe heart failure for 2 wk. Then dosage doubled every 2 wk as tolerated. *Maximum:* 200 mg daily.

**DOSAGE ADJUSTMENT** For elderly patients or patients with hepatic impairment, initial dosage reduced with gradual dose titration.

Route	Onset	Peak	Duration
P.O.	60 min	1–2 hr	Unknown
P.O. (E.R.)	Unknown	6–12 hr	Unknown
I.V.	Unknown	20 min	Unknown

## Mechanism of Action

Inhibits stimulation of beta<sub>1</sub>-receptor sites, located mainly in the heart, resulting in decreased cardiac excitability, cardiac output, and myocardial oxygen demand. These effects help relieve angina, minimize cardiac tissue damage from a myocardial infarction, and help relieve symptoms of heart failure. Metoprolol also helps reduce blood pressure by decreasing renal release of renin.

## Contraindications

*For all indications:* Hypersensitivity to metoprolol, other beta blockers, or their components; *For angina and hypertension:* Cardiogenic shock, heart block greater than first degree, overt cardiac failure, sinus bradycardia; *For myocardial infarction:* Heart rate less than 45 beats/minute, moderate to severe cardiac failure, second- and third- degree heart block, significant first- degree heart block (P-R interval 0.24 seconds or greater), systolic blood pressure less than 100 mm Hg

# Interactions

## DRUGS

*alpha-adrenergic agents such as alpha-methyldopa, betanidine, guanethidine, reserpine:* Possibly increased antihypertensive effects

*calcium channel blockers:* Increased risk of additive reduction in myocardial contractility

*catecholamine-depleting drugs such as reserpine:* Possibly additive effect resulting in hypotension or marked bradycardia

*CYP2D6 inhibitors such as antiarrhythmics (propafenone, quinidine), antidepressants (bupropion, clomipramine, desipramine, fluoxetine, fluvoxamine, paroxetine, sertraline), antifungals (terbinafine), antihistamines (diphenhydramine), antimalarials (hydroxychloroquine, quinidine), antipsychotics (chlorpromazine, fluphenazine, haloperidol, thioridazine), antiretrovirals (ritonavir):* Increased plasma metoprolol level causing decrease in the cardioselectivity of metoprolol

*clonidine:* Increased risk of bradycardia and hypotension; increased risk of rebound hypertension when clonidine is discontinued

*digoxin, other beta-blockers:* Decreased heart rate and slowed atrioventricular conduction

*dipyridamole:* Possibly altered heart rate

*ergot alkaloids:* Possibly enhanced vasoconstrictive action of ergot alkaloids

*hydralazine:* Increased metoprolol concentration

*MAO inhibitors:* Possibly significant hypertension

*other antihypertensives:* Additive hypotensive effect

*prazosin:* Possibly increased postural hypotensive effect of first dose of prazosin

## FOODS

*all foods:* Increased bioavailability of metoprolol

## Adverse Reactions

**CNS:** Anxiety, confusion, **CVA**, depression, dizziness, drowsiness, fatigue, hallucinations, headache, insomnia, nightmares, paresthesia, short-term memory loss, somnolence, syncope, tiredness, vertigo, weakness

**CV:** Angina, **arrhythmias (including AV block and bradycardia)**, **arterial insufficiency**, **cardiac arrest**, **cardiogenic shock**, chest pain, decreased HDL level, increased triglyceride levels, gangrene of extremity, **heart failure**, hypertension, orthostatic hypotension, palpitations, peripheral edema

**EENT:** Blurred vision, dry eyes or mouth, nasal congestion, rhinitis, taste disturbance, tinnitus

**GI:** Constipation, diarrhea, flatulence, heartburn, **hepatitis**, nausea, vomiting

**GU:** Decreased libido, impotence

**HEME:** **Agranulocytosis**, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, myalgia

**RESP:** **Bronchospasm**, dyspnea, shortness of breath

**SKIN:** Alopecia, diaphoresis, photosensitivity, pruritus, rash, urticaria, worsening of psoriasis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that patients undergoing noncardiac major surgery should not begin a high-dose regimen using extended-release metoprolol because such use in patients with cardiovascular risk factors has been associated with bradycardia, hypotension, stroke, and death. However, also be aware that beta-blocker therapy such as metoprolol that is already in place should not be routinely discontinued prior to major surgery.
- Use metoprolol with extreme caution in patients with bronchospastic disease who don't respond to or can't tolerate other antihypertensives. Expect to give smaller doses more often to avoid the higher plasma levels in longer dosage intervals.
- Use cautiously in patients with angina or hypertension who have congestive heart failure because beta blockers such as metoprolol can further depress myocardial contractility, worsening heart failure.
- Expect patients with acute MI who can't tolerate initial dosage or who delay treatment to start with maintenance dosage, as prescribed and tolerated.
- Before starting therapy for heart failure, expect to give an ACE inhibitor, digoxin, and a diuretic to stabilize patient.
- Be aware that if patient has pheochromocytoma, alpha blocker therapy should start first, followed by metoprolol to prevent paradoxical increase in blood pressure from attenuation of beta-mediated vasodilation in skeletal muscle.
- Be aware that metoprolol dosage for heart failure is highly individualized. Monitor patient for evidence of worsening heart failure during dosage increases. If heart failure worsens, expect to increase diuretic dosage and possibly decrease metoprolol dosage or temporarily discontinue drug, as prescribed. Metoprolol dosage shouldn't be increased until worsening heart failure has been stabilized.
- If patient with heart failure develops symptomatic bradycardia, expect to decrease the metoprolol dosage.

**WARNING** Know that if dosage exceeds 400 mg daily, patient should be monitored for bronchospasm and dyspnea because metoprolol competitively blocks beta<sub>2</sub>-adrenergic receptors in bronchial and vascular smooth muscles.

**WARNING** When substituting metoprolol for clonidine, expect to gradually reduce clonidine and increase metoprolol dosage over several days. Given together, these drugs have additive hypotensive effects.

- Know that E.R. capsule form can be administered via a nasogastric tube by mixing the contents of the opened capsule with water and drawing mixture up into a syringe. Gently shake the mixture for about 10 seconds, then flush it through the tube. Rinse the tube with water until all of the drug is washed out.
- Assess ECG of patients who take metoprolol because they may be at risk for AV block. If AV block results from depressed AV node conduction, prepare to give appropriate drug, as ordered, or assist with insertion of temporary pacemaker.
- Check for signs of poor glucose control in patient with diabetes mellitus. Metoprolol may interfere with therapeutic effects of insulin and oral antidiabetic drugs. It also may mask evidence of hypoglycemia, such as palpitations, tachycardia, and tremor.
- Monitor patient with hyperthyroidism closely because beta-adrenergic blockers such as metoprolol may mask signs of hyperthyroidism, such as tachycardia. Also know that abrupt discontinuation of metoprolol should be avoided because thyroid storm could be precipitated.
- Monitor patient with peripheral vascular disease for evidence of arterial insufficiency (coldness, pain, and pallor in affected extremity). Metoprolol can precipitate or aggravate peripheral vascular disease.
- Be aware that patients with a history of severe anaphylactic reactions may be more reactive to repeated challenges of the allergen while taking beta-blocker therapy, such as metoprolol, and may be unresponsive to the usual doses of epinephrine used to treat an allergic reaction.

**WARNING** Expect to taper dosage over 1 to 2 weeks when drug is discontinued; stopping abruptly can cause myocardial ischemia, MI, severe hypertension, or

ventricular arrhythmias, especially in patients with cardiac disease.

## PATIENT TEACHING

- Instruct patient to take metoprolol with food at the same time each day—once daily for E.R. tablets. Explain that he may halve tablets but not chew or crush them.
- Tell patient unable to swallow E.R. capsules that the capsule may be opened and sprinkled over soft food such as applesauce or pudding. Mixture must be swallowed within 60 minutes and never stored for later use.
- Advise patient to notify prescriber if pulse rate falls below 60 beats/minute or is significantly lower than usual.
- Urge diabetic patient to check blood glucose level often during therapy.
- Caution patient not to stop drug abruptly.

**metronidazole**

**Flagyl, Flagyl ER**

**metronidazole  
hydrochloride**

**Flagyl I.V. RTU**

## Class and Category

*Pharmacologic class:* Nitroimidazole

*Therapeutic class:* Antiprotozoal

# Indications and Dosages

- *To treat systemic anaerobic infections caused by Bacteroides fragilis, Clostridium difficile, Clostridium perfringens, Eubacterium, Fusobacterium, Peptococcus, Peptostreptococcus, and Veillonella species*

## CAPSULES, TABLETS

**Adults.** 7.5 mg/kg up to 1,000 mg every 6 hr for 7 days or longer. *Maximum:* 4,000 mg daily.

## I.V. INFUSION

**Adults.** *Initial:* 15 mg/kg infused over 1 hr and then 7.5 mg/kg up to 1,000 mg infused over 1 hr every 6 hr for 7 days or longer. *Maximum:* 4,000 mg daily.

- *To treat amebiasis (Entamoeba histolytica)*

## CAPSULES, TABLETS

**Adults.** *For acute amebic dysentery:* 750 mg three times daily for 5 to 10 days. *For amebic liver abscess:* 500 or 750 mg three times daily for 5 to 10 days.

**Children.** 35 to 50 mg/kg/24 hrs divided into three times daily for 10 days.

- *To treat trichomoniasis (Trichomonas vaginalis)*

## CAPSULES, TABLETS

**Adults.** 2,000 mg as a single dose, 1,000 mg twice daily for 1 day, or 250 mg three times daily for 7 days.

- *To prevent postoperative bowel infection in elective colorectal surgery which is contaminated or potentially contaminated*

## I.V. INFUSION

**Adults.** 15 mg/kg infused 30 to 60 min 1 hr before surgery and then 7.5 mg/kg infused over 30 to 60 min 6 and 12 hr after initial dose.

➤ *To treat bacterial vaginosis*

## E.R. TABLETS

**Adult nonpregnant women.** 750 mg once daily for 7 days.

**DOSAGE ADJUSTMENT** For patients with severe hepatic impairment, dosage reduced by 50%.

\*Topical and vaginal forms presented in appendix.

## Mechanism of Action

Undergoes intracellular chemical reduction during anaerobic metabolism. After metronidazole is reduced, it damages DNA's helical structure and breaks its strands, which inhibits bacterial nucleic acid synthesis and causes cell death.

## Incompatibilities

Don't administer I.V. metronidazole with aluminum needles or hubs or through same I.V. line as other drugs.

## Contraindications

Alcohol use including products containing propylene glycol during and for at least 3 days after metronidazole therapy; first trimester of pregnancy; hypersensitivity to metronidazole, other nitroimidazole derivatives, or their components; use of disulfiram within past two weeks

# Interactions

## DRUGS

*5-fluorouracil*: Decreased clearance of 5-fluorouracil and potential for 5-fluorouracil toxicity

*amiodarone, carbamazepine, cyclosporine, phenytoin, quinidine, tacrolimus*: Increased plasma levels of these drugs

*busulfan*: Increased risk of serious busulfan toxicity

*cimetidine and other drugs that inhibit CYP450 enzymes*: Possibly delayed elimination and increased blood level of metronidazole

*disulfiram*: Possibly combined toxicity, with confusion and psychotic reactions

*lithium*: Possible development of elevated lithium levels with potential for toxicity in patients on high doses

*oral anticoagulants*: Possibly increased anticoagulant effect

*phenobarbital, phenytoin, and other drugs that induce*

*microsomal liver enzyme activity*: Possibly accelerated elimination of metronidazole and decreased effectiveness

## ACTIVITIES

*alcohol use*: Possibly disulfiram-like effects

# Adverse Reactions

**CNS:** **Aseptic meningitis (parenteral form)**, ataxia, asthenia, chills, confusion, depression, dizziness, dysarthria, **encephalopathy**, fever, headache, hypoesthesia, incoordination, insomnia, irritability, jumpy eye movements, light-headedness, malaise, numbness, paresthesia, peripheral neuropathy, psychosis, **seizures** (high doses), somnolence, syncope, weakness, vertigo

**CV:** Chest pain, palpitations, peripheral edema, tachycardia

**EENT:** Dry mouth, lacrimation (topical form), metallic taste, nasal congestion, nystagmus, optic neuropathy, pharyngitis

**GI:** Abdominal cramps or pain, anorexia, diarrhea, elevated liver enzymes, **hepatic failure or hepatotoxicity** (patients with Cockayne syndrome), nausea, **pancreatitis**, vomiting

**GU:** Burning or irritation of sexual partner's penis, candidal cervicitis or vaginitis, chromaturia, dark urine, decreased libido, dryness of vagina or vulva, dyspareunia, dysuria, proctitis, urinary frequency

**HEME:** **Agranulocytosis**, eosinophilia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, dysarthria, muscle spasms, myalgia

**RESP:** Dyspnea

**SKIN:** Burning or stinging sensation, erythema, flushing, hyperhidrosis, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**; **angioedema**; **drug reaction with eosinophilia and systemic symptoms (DRESS)**; infusion-site edema, pain, or tenderness

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant. Alternatively, a mother may choose to pump and discard breast milk for the duration of drug therapy and for 24 hours after therapy ends and feed her infant breast milk stored before therapy began or formula.

## Nursing Considerations

- Use parenteral metronidazole with extreme caution in patients with Cockayne syndrome, because acute hepatic failure and severe hepatotoxicity have occurred, with some fatalities. If no other treatment is available, expect to obtain liver function studies before metronidazole is given parenterally, again within the first 2 to 3 days after treatment is initiated, frequently during therapy, and at the end of therapy. If liver enzymes become elevated, expect metronidazole to be discontinued and liver enzymes monitored until they have returned to baseline values.
- Use cautiously in patients with CNS diseases.
- Use cautiously in patients with blood dyscrasias or a history of such because metronidazole therapy has caused agranulocytosis, leukopenia, and neutropenia in some patients.
- Don't give I.V. administration by direct I.V. injection.
- Discontinue primary I.V. infusion during metronidazole infusion.

**WARNING** Know that if patient has adverse CNS reactions, such as peripheral neuropathy or seizures, prescriber must be told and drug stopped immediately.

- Monitor patient with severe liver disease because slowed metronidazole metabolism may cause drug to accumulate in body and increase the risk of adverse effects.
- Monitor patients with end-stage renal disease who are not on hemodialysis or patients with severe renal impairment for adverse reactions, because reduced urinary excretion may cause metronidazole and its metabolites to accumulate in the body.
- Monitor CBC and culture and sensitivity tests if therapy lasts longer than 10 days or if second course of treatment is needed.
- Monitor patient's neurologic status throughout metronidazole therapy. If abnormal neurologic signs and symptoms occur, notify prescriber and

expect to discontinue drug.

- Be aware that parenteral form of metronidazole contains 790 mg of sodium per 100 ml. Monitor patients predisposed to edema or who are receiving corticosteroids or a reduced-sodium diet.
- Assess patient for fungal superinfections. Candidiasis may occur and present with more serious symptoms during therapy with metronidazole and requires treatment with a candidacidal agent.
- Be aware that metronidazole may interfere with certain chemistry values, such as alanine aminotransferase (AST, SGOT), aspartate aminotransferase, glucose hexokinase, lactate dehydrogenase (LDH), and triglycerides.
- Monitor patient with Crohn's disease exposed to metronidazole at high doses for extended periods of time because these patients have an increased risk of extraintestinal and gastrointestinal cancers such as breast and colon cancers.

## **PATIENT TEACHING**

- Urge patient to take metronidazole at evenly spaced intervals during the day and with food to minimize adverse GI reactions. except for E.R. tablets, which should be taken 1 hour before or 2 hours after a meal.
- Urge patient to complete the entire course of therapy.
- Caution patient to avoid alcohol during therapy and for at least 3 days afterward.
- Advise patient to avoid hazardous activities until drug's CNS effects are known and to report any abnormal neurologic signs or symptoms, such as numbness, seizures, weakness, or vision changes.
- If patient reports dry mouth, suggest ice chips or sugarless hard candy or gum; suggest a dental visit if dryness lasts longer than 2 weeks.
- Instruct patient to notify prescriber if no improvement occurs within a few days of taking tablets or capsules.
- Inform patient with trichomoniasis that her male sexual partners should wear condoms during her treatment and that they may need treatment themselves to prevent reinfection.
- Urge patient to follow up with prescriber to make sure infection is gone.
- Tell patient with Cockayne syndrome who is receiving metronidazole to stop drug immediately if signs and symptoms of liver dysfunction occur,

such as abdominal pain, change in skin or stool color, or nausea, and to notify prescriber.

## micafungin sodium

### Mycamine

## Class and Category

*Pharmacologic class:* Echinocandin

*Therapeutic class:* Antifungal

## Indications and Dosages

➤ *To treat esophageal candidiasis*

### I.V. INFUSION

**Adults.** 150 mg infused over 1 hr once daily.

**Children age 4 months and overweighing more than 30 kg.** 2.5 mg/kg infused over 1 hr once daily. *Maximum:* 150 mg once daily.

**Children age 4 months and overweighing 30 kg or less.** 3 mg/kg infused over 1 hr once daily.

➤ *To prevent Candida infection in patients undergoing hematopoietic stem cell transplantation*

### I.V. INFUSION

**Adults.** 50 mg infused over 1 hr once daily.

**Children age 4 months and over.** 1 mg/kg infused over 1 hr once daily. *Maximum:* 50 mg once daily.

- *To treat candidemia, acute disseminated candidiasis, and Candida peritonitis and abscesses*

## **I.V. INFUSION**

**Adults.** 100 mg infused over 1 hr once daily.

**Children age 4 months and over.** 2 mg/kg infused over 1 hr once daily. *Maximum:* 100 mg once daily.

- *To treat candidemia, acute disseminated candidiasis, and Candida peritonitis and abscesses without meningoencephalitis and/or ocular dissemination*

## **I.V. INFUSION**

**Adults.** 150 mg infused over 1 hr once daily.

**Children age 4 months and over.** 2 mg/kg/day infused over 1 hr once daily. *Maximum:* 100 mg once daily.

**Children less than 4 months of age.** 4 mg/kg infused over 1 hr once daily.

## **Mechanism of Action**

Inhibits synthesis of 1,3-beta-D-glucan, which is an essential component of the *Candida* fungal cell wall. Without 1,3-beta-D-glucan, the fungal cell dies.

## **Contraindications**

Hypersensitivity to micafungin, other echinocandins, or their components

## **Incompatibilities**

Mixing or infusing with other drugs may cause micafungin to precipitate.

# Interactions

## DRUGS

*itraconazole, nifedipine, sirolimus*: Increased plasma levels of these drugs

## Adverse Reactions

**CNS:** Anxiety, delirium, dizziness, dysgeusia, fatigue, fever, headache, insomnia, **intracranial hemorrhage**, rigors, **seizures**, somnolence

**CV:** **Arrhythmia**, **atrial fibrillation**, **bradycardia**, **cardiac arrest**, **deep vein thrombosis**, hypertension, **hypotension**, **MI**, peripheral edema, phlebitis, tachycardia, **shock**, vasodilation

**EENT:** Epistaxis, mucosal inflammation

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, **hepatic dysfunction**, **hepatitis**, hiccups, hyperbilirubinemia, jaundice, nausea, vomiting, **worsening hepatic failure**

**GU:** **Acute renal failure**, **anuria**, elevated blood urea and serum creatinine levels, oliguria, **renal tubular necrosis**

**HEME:** Anemia, **coagulopathy**, **disseminated intravascular coagulation (DIC)**, eosinophilia, **hemolytic anemia**, **leukopenia**, **lymphopenia**, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**RESP:** **Apnea**, cough, **cyanosis**, dyspnea, **hypoxia**, pneumonia, **pulmonary embolism**

**SKIN:** Erythema, **erythema multiforme**, flushing, necrosis, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Acidosis**, **anaphylaxis**, **angioedema**, bacteremia, **hyperkalemia**, **hybernatiemia**, **hypocalcemia**,

**hypokalemia, hypomagnesemia, hyponatremia, hypophosphatemia**, injection-site reactions including phlebitis and thrombophlebitis, **sepsis**

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm although animal studies suggest a possibility.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Use cautiously in patients with hepatic insufficiency.
- Reconstitute micafungin by adding 5 ml 0.9% sodium chloride injection, USP or 5% dextrose injection, USP solution to each 50-mg vial being used (to yield 10 mg micafungin/ml) and to each 100-mg vial being used (to yield 20 mg micafungin/ml). Swirl vial gently to minimize excessive foaming. For adult patients, add reconstituted solution to 100 ml 0.9% sodium chloride injection, USP or 5% dextrose injection, USP. For pediatric patients, follow manufacturer guidelines for calculating volume to use for dilution. Give solution for both adults and children over 1 hour after flushing an existing I.V. line with 0.9% sodium chloride injection, USP. Protect diluted solution from light, although the infusion drip chamber or tubing does not need to be covered.
- Administer concentrations greater than 1.5 mg/ml through a central catheter to minimize risk of infusion reactions.
- Monitor infusion rate carefully because infusions that took less than 1 hour to infuse have been associated with more frequent hypersensitivity

reactions.

**WARNING** Monitor patient closely for hypersensitivity reactions, including anaphylaxis and angioedema. Stop infusion immediately if present, notify prescriber, and provide supportive care, as prescribed.

- Monitor patient's liver and renal function closely throughout therapy because liver and renal abnormalities may occur in patients receiving micafungin.
- Monitor hematologic status closely because hematologic abnormalities may occur. If they do, monitor patient closely. If patient's condition worsens, expect micafungin to be discontinued.

## PATIENT TEACHING

- Instruct patient to report any infusion-site discomfort immediately.
- Tell patient to report any unusual or persistent signs and symptoms to prescriber.
- Stress importance of seeking emergency treatment if difficulty breathing or swallowing occurs or other signs of an allergic reaction occurs.
- Advise women of childbearing age to notify prescriber if pregnancy is known or suspected.

# midazolam hydrochloride

## Nayzilam, Versed

## Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Sedative-hypnotic

*Controlled substance schedule: IV*

## Indications and Dosages

- *To induce preoperative sedation or amnesia, to control preoperative anxiety*

### SYRUP

**Children ages 6 months to 16 years.** 0.25 to 0.5 mg/kg as a single dose 30 to 45 min before surgery. *Usual:* 0.5 mg/kg. *Maximum:* 20 mg.

### I.V. INJECTION

**Adults age 60 and over and adults who are debilitated or chronically ill.** *Initial:* 1.5 mg over 2 min immediately before procedure. *Maintenance:* After 2-min waiting period, dosage adjusted to desired level in 25% increments, as ordered. *Maximum:* 1 mg in 2 min.

**Adults under age 60 and adolescents.** *Initial:* Up to 2.5 mg over 2 min immediately before procedure. After 2-min waiting period, dosage adjusted to desired level in 25% increments, as ordered. *Maximum:* 5 mg.

**Children ages 6 to 12.** *Initial:* 0.025 to 0.05 mg/kg, over 2 min up to 0.4 mg/kg, if needed immediately before procedure. *Maintenance:* After a 2- to 3-min waiting period, dosage adjusted as needed. *Maximum:* 10 mg.

**Children ages 6 months to 5 years.**

*Initial:* 0.05 to 0.1 mg/kg, over 2 min up to 0.6 mg/kg, if needed immediately before procedure. *Maintenance:* After waiting 2 to 3 min, dosage adjusted, as needed. *Maximum:* 6 mg.

### I.M. INJECTION

**Adults age 60 and over.** 0.02 to 0.05 mg/kg as a single dose 30 to 60 min before surgery.

**Adults under age 60 and adolescents.** 0.07 to 0.08 mg/kg as a single dose 30 to 60 min before surgery.

**Children ages 6 months to 12 years.** 0.1 to 0.15 mg/kg, up to 0.5 mg/kg for more anxious patients as a single dose 30 to 60 min before surgery. *Maximum:* 10 mg.

**DOSAGE ADJUSTMENT** For elderly patients and patients who are chronically ill, maintenance dosage reduced by 50%. For adults who have been premedicated with an opiate, maintenance dosage reduced by 25%.

➤ *To relieve agitation and anxiety in mechanically ventilated patients*

## **I.V. INFUSION**

**Adults.** *Initial:* 0.01 to 0.05 mg/kg infused over several min, repeated at 10- to 15-min intervals until adequate sedation occurs. *Maintenance:* 0.02 to 0.1 mg/kg/hr initially, adjusted at intervals of 30 min to desired level in 25% to 50% increments, as ordered. After achieving desired level of sedation, infusion rate decreased by 10% to 25% every few hr, as ordered, until minimum effective infusion rate is determined.

**Children.** *Initial bolus:* 0.05 to 0.2 mg/kg over 2 to 3 min. *Maintenance:* 0.06 to 0.12 mg/kg/hr by continuous infusion with dosage adjusted, as needed, to maintain effect.

**Infants over age 32 weeks.** 0.06 mg/kg/hr by continuous infusion with rate adjusted, as needed.

**Infants under age 32 weeks.** *Initial:* 0.03 mg/kg/hr by continuous infusion with rate adjusted, as needed.

**DOSAGE ADJUSTMENT** For children who are hemodynamically compromised, the usual loading dose is titrated in small increments, separated by 2 to 3 min.

- *To treat acute, intermittent, stereotypic episodes of frequent seizure activity (i.e. seizure clusters, acute repetitive seizures) that are distinct from a patient's usual seizure pattern in patients with epilepsy*

## NASAL SPRAY

**Adults and children age 12 and over.** 5 mg (1 spray) into one nostril. After 10 min, an additional 5 mg (1 spray) into the opposite nostril, if needed. *Maximum:* 10 mg (2 sprays) to treat a single episode and used no more than one episode every three days and no more than 5 episodes a month.

Route	Onset	Peak	Duration
I.V.*	1.5–5 min	Rapid	2–6 hr
I.M.*	5–15 min	15–60 min	2–6 hr
I.M.†	30–60 min	Unknown	Unknown

\* For sedation.

† For amnesia.

## Mechanism of Action

May exert sedating effect by increasing activity of gamma-aminobutyric acid, a major inhibitory neurotransmitter in the brain. As a result, midazolam produces a calming effect, relaxes skeletal muscles, and—at high doses—induces sleep.

## Contraindications

Acute angle-closure glaucoma; acute pulmonary insufficiency; debilitated or elderly patients outside the ICU setting; hypersensitivity to midazolam, other

benzodiazepines, or their components; severe chronic obstructive pulmonary disease

## Interactions

### DRUGS

*cimetidine, diltiazem, erythromycin, fluconazole, itraconazole, ketoconazole, ritonavir, saquinavir, verapamil:*

Intense and prolonged sedation caused by reduced midazolam metabolism

*CNS depressants (secobarbital), droperidol-fentanyl combination, opioids (fentanyl, meperidine, morphine):* Possibly increased CNS and respiratory depression and hypotension

*halothane:* Reduced minimum alveolar concentration of halothane required during maintenance of anesthesia

*pancuronium:* Potentiated effect of pancuronium

*sodium valproate:* Increased effect of midazolam

*thiopental:* Slight reduction in dosage requirement of thiopental following I.M. midazolam

## Adverse Reactions

**CNS:** Agitation, delirium, or dreaming during emergence from anesthesia; anxiety; ataxia; chills; combativeness; confusion; dizziness; drowsiness; euphoria; excessive sedation; headache; insomnia; lethargy; nervousness; nightmares; paresthesia; prolonged emergence from anesthesia; restlessness; retrograde amnesia; sleep disturbance; slurred speech; **suicidal ideation** (nasal spray form); weakness; yawning

**CV:** **Cardiac arrest**, **hypotension**, **nodal rhythm**, **PVCs**, tachycardia, **vasovagal episodes**

**EENT:** Blurred vision, diplopia, or other vision changes; increased salivation; **laryngospasm**; miosis; nystagmus; toothache

**GI:** Hiccups, nausea, retching, vomiting

**RESP:** **Airway obstruction, bradypnea, bronchospasm**, coughing, decreased tidal volume, dyspnea, hyperventilation, **respiratory arrest, shallow breathing**, tachypnea, wheezing

**SKIN:** Pruritus, rash, urticaria

**Other:** Injection-site burning, edema, induration, pain, redness, and tenderness

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry for Nayzilam brand: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Drug may cause fetal harm such as an increased risk of congenital malformations if given in the first trimester.
- Drug is not recommended for obstetrical use because other benzodiazepines given in the last weeks of pregnancy have resulted in neonatal CNS depression. Withdrawal can occur in neonates when mother has used the nasal spray form during the later stages of pregnancy.

### LABOR & DELIVERY

- Drug is not recommended for use during labor and delivery.

### LACTATION

- Drug is excreted in breast milk.
- Breastfeeding is not recommended during drug therapy. But if nasal spray formulation is used with breastfeeding, infant should be monitored for lethargy, poor sucking, and somnolence.

# Nursing Considerations

- Determine whether patient consumes alcohol or takes antibiotics, antihypertensives, or protease inhibitors because these substances can produce an intense and prolonged sedative effect when taken with midazolam.

**WARNING** Know that midazolam, except for nasal spray form, is given only in hospital or ambulatory care settings that allow continuous monitoring of cardiac and respiratory function. Keep resuscitative drugs and equipment at hand.

- Know that repeated or lengthy use of sedation drugs such as midazolam and general anesthetics during procedures or surgeries should be avoided in children younger than 3 years of age or in pregnant women during their third trimester, because the combined use may affect the development of children's brains.
- Know that midazolam injection may be combined with D<sub>5</sub>W, normal saline solution or lactated Ringer's solution. With D<sub>5</sub>W and normal saline, solution is stable for 24 hours. With lactated Ringer's, solution is stable for 4 hours.
- Mix injection in same syringe with atropine sulfate, meperidine hydrochloride, morphine sulfate, or scopolamine hydrobromide, if needed. The resulting solution is stable for 30 minutes.
- Assess level of consciousness frequently because the range between sedation and unconsciousness or disorientation is narrow with midazolam.
- Be aware that recovery time is usually 2 hours but may be up to 6 hours.

## PATIENT TEACHING

- Instruct patient how to administer nasal spray form, if prescribed for seizure activity. Stress importance of avoiding opioid use unless under supervision of a prescriber because of risk of severe respiratory depression and sedation.
- Inform patient that he may not remember procedure because midazolam produces amnesia.

- Advise patient to avoid hazardous activities until drug's adverse CNS effects, such as dizziness and drowsiness, have worn off.
- Instruct patient to avoid alcohol and other CNS depressants for 24 hours after receiving drug after surgery or a procedure, as directed by prescriber.
- Warn patient prescribed nasal spray form to avoid alcohol or other CNS depressants during midazolam nasal spray therapy to avoid risk of airway obstruction, apnea, or profound hypoventilation.
- Urge family or caregiver to watch patient taking nasal spray closely for suicidal tendencies, especially when therapy starts or dosage changes.

**miglitol**

**Glyset**

## **Class and Category**

*Pharmacologic class:* Alpha glucosidase inhibitor

*Therapeutic class:* Antidiabetic

## **Indications and Dosages**

➤ *As adjunct to manage type 2 diabetes mellitus*

### **TABLETS**

**Adults. Initial:** 25 mg three times daily with first bite of each meal. Or, 25 mg daily with first bite of a meal, increased gradually to 25 mg three times daily with first bite of each meal. After 4 to 8 wk, dosage increased to 50 mg three times daily for 3 months if needed, with a further

increase to 100 mg three times, if needed. *Maximum:* 100 mg three times daily.

Route	Onset	Peak	Duration
P.O.	Rapid	2-3 hr	Unknown

## Mechanism of Action

Inhibits intestinal glucoside hydrolase enzymes, which normally hydrolyze disaccharides and oligosaccharides to glucose and other monosaccharides. This action delays carbohydrate absorption and digestion and reduces postprandial blood glucose level.

## Contraindications

Chronic intestinal diseases associated with marked disorders of absorption or digestion, colonic ulceration, conditions that may deteriorate as a result of increased gas formation in the intestine, diabetic ketoacidosis, hypersensitivity to miglitol or its components, inflammatory bowel disease, partial intestinal obstruction, predisposition to intestinal obstruction

## Interactions

### DRUGS

*digestive enzyme preparations, intestinal adsorbents (activated charcoal):* Decreased miglitol effects

*digoxin:* Possibly decreased blood digoxin level

*insulin, sulfonylureas:* Increased risk and severity of hypoglycemia

*propranolol:* Decreased bioavailability of these drugs

## Adverse Reactions

**GI:** Abdominal distention or pain, diarrhea, flatulence, **hepatotoxicity**, ileus including paralytic ileus, nausea, pneumatosis cystoides intestinalis (rare), subileus

**HEME:** Low serum iron level

**SKIN:** Rash (transient)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

- Use miglitol cautiously in patient with serum creatinine level above 2 mg/dl.
- Be aware that some patients with type 2 diabetes also may receive insulin or a sulfonylurea as an adjunct to miglitol therapy. Monitor these patients closely for hypoglycemia because insulin and sulfonylureas may cause hypoglycemia, and miglitol therapy may make it more severe. If hypoglycemia occurs, use an oral glucose product such as dextrose to treat mild-to-moderate hypoglycemia rather than sucrose, whose hydrolysis to fructose and glucose is inhibited by miglitol.
- Give miglitol with first bite of each meal. Drug must have arrived at site of enzymatic action when carbohydrates reach small intestine.

- Review patient's HbA<sub>1C</sub> level, as appropriate, to monitor long-term glucose control.
- Monitor patient for evidence of overdose, such as transient increases in abdominal discomfort, diarrhea, and flatulence (but not hypoglycemia).
- Monitor patient for constipation, diarrhea, mucus discharge, or rectal bleeding suggestive of pneumatosis cystoides intestinalis. If suspected, notify prescriber and prepare patient for diagnostic imaging, as ordered. If confirmed, expect drug to be discontinued.

## **PATIENT TEACHING**

- Explain that miglitol is an adjunct to diet, which is the primary treatment for type 2 diabetes mellitus.
- Instruct patient to take drug with first bite of each meal.
- Describe signs and symptoms of hypoglycemia and pathophysiology of diabetes to patient and family members.
- Alert patient that if miglitol is the only drug patient takes to control blood glucose level, it won't cause hypoglycemia.
- Instruct patient who takes insulin or a sulfonylurea with miglitol to keep a source of glucose readily available to reverse hypoglycemia.
- Explain importance of monitoring blood glucose levels.
- Explain that adverse GI reactions usually decrease in frequency and intensity over time.
- Teach obese patient about calorie restriction, diet, regular exercise, and weight loss, as indicated.
- Instruct patient to report to prescriber persistent or severe constipation, diarrhea, mucus discharge, or rectal bleeding.

**milnacipran hydrochloride**

**Savella**

# Class and Category

*Pharmacologic class:* Selective norepinephrine and serotonin reuptake inhibitor (SSNRI)

*Therapeutic class:* Antifibromyalgia

# Indications and Dosages

➤ *To manage fibromyalgia*

## TABLETS

**Adults.** *Initial:* 12.5 mg on day 1; 12.5 mg twice daily on days 2 and 3; 25 mg twice daily on days 4 through 7; and then 50 mg twice daily, increased if needed to 100 mg twice daily. *Maximum:* 100 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment (creatinine clearance of 5 to 29 ml/min), maintenance dosage reduced by half.

Route	Onset	Peak	Duration
P.O.	Unknown	2–4 hr	Unknown

# Mechanism of Action

Inhibits reuptake of norepinephrine and serotonin by CNS neurons without affecting uptake of dopamine or other neurotransmitters, thereby increasing amount of norepinephrine and serotonin available in nerve synapses. Elevated norepinephrine and serotonin levels may improve symptoms of fibromyalgia, including central analgesic effect.

# Contraindications

Hypersensitivity to milnacipran or its components, use within 14 days of MAO inhibitor, including I.V. methylene blue and linezolid

## Interactions

### DRUGS

*amphetamines, buspirone, fentanyl, I.V. methylene blue, linezolid, lithium, MAO inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, St. John's Wort, tramadol, tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

*clomipramine:* Increased risk of euphoria and postural hypotension

*clonidine:* Possibly inhibited antihypertensive effect

*CNS-active drugs:* Possibly increased CNS effects

*digoxin:* Possibly increased risk of postural hypotension and tachycardia

*epinephrine, norepinephrine:* Increased risk of arrhythmias and paroxysmal hypertension

*MAO inhibitors:* Possibly hyperpyretic episodes, hypertensive crisis, serotonin syndrome, and severe seizures

### ACTIVITIES

*alcohol use:* Increased risk of liver impairment

## Adverse Reactions

**CNS:** Aggression, anger, anxiety, chills, delirium, depression, dizziness, fatigue, fever, hallucinations, headache, **homicidal ideation**, hypoesthesia, insomnia,

irritability, loss of consciousness, migraine, **neuroleptic malignant syndrome**, Parkinsonism, paresthesia, **seizures**, **serotonin syndrome**, **suicidal ideation**, tremor  
**CV:** Chest pain, hypercholesterolemia, hypertension, **hypertensive crisis**, increased heart rate, palpitations, peripheral edema, **supraventricular tachycardia**, tachycardia, **Takotsubo cardiomyopathy**  
**EENT:** Accommodation abnormality, angle closure glaucoma, blurred vision, dry mouth, mydriasis  
**ENDO:** Galactorrhea, hot flashes, hyper-prolactinemia  
**GI:** Abdominal distention or pain, **acute pancreatitis**, anorexia, constipation, diarrhea, dyspepsia, elevated liver enzymes, gastroesophageal reflux, flatulence, **hepatitis**, jaundice, liver dysfunction, nausea, vomiting  
**GU:** **Acute renal failure**, cystitis, decreased libido, dysuria, ejaculation disorder, erectile dysfunction, prostatitis, scrotal or testicular pain, testicular swelling, urinary hesitation, urine retention, urethral pain, UTI  
**HEME:** **Leukopenia**, **neutropenia**, **thrombocytopenia**  
**MS:** **Rhabdomyolysis**  
**RESP:** Dyspnea, upper respiratory infection  
**SKIN:** **Erythema multiforme**, flushing, hyperhidrosis, night sweats, pruritus, rash, **Stevens-Johnson syndrome**  
**Other:** **Hyponatremia**, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-877-643-3010, email: pregnancyregistries@incresearch.com, or www.savelapregnancyregistry.com.
- Drug may cause fetal harm, especially if given during the third trimester and neonate may require prolonged hospitalization, respiratory support, and tube feeding immediately upon birth.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Keep in mind that because milnacipran may aggravate liver disease, it shouldn't be given to patients with alcohol addiction or chronic liver disease.
- Ensure patient has had an ophthalmic examination before milnacipran therapy is begun because pupillary dilation that occurs with drug use may trigger an angle closure attack in a patient with anatomically narrow angles who does not have a patent iridectomy.
- Use cautiously in patients with cardiac disease, mild to moderate renal impairment and patients with significant hypertension. Also use cautiously in patients with a history of dysuria, especially men with prostatic hypertrophy, prostatitis, and other lower urinary tract obstructive disorders.
- Know that at least 14 days should elapse between stopping an MAO inhibitor and starting milnacipran. At least 5 days should elapse between stopping milnacipran and starting an MAO inhibitor.
- Measure patient's blood pressure and heart rate before starting and periodically during milnacipran therapy because drug can raise blood pressure and heart rate. If hypertension or tachycardia occurs and persists, notify prescriber and expect to reduce dosage or discontinue drug.
- Watch closely for suicidal tendencies, especially when therapy starts and dosage changes.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of selective serotonin reuptake inhibitors such as milnacipran. Signs and symptoms include agitation, confusion, diaphoresis,

diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. In its most severe form, it can resemble neuroleptic malignant syndrome with autonomic instability with possible rapid fluctuation of vital signs, mental status changes, and muscle rigidity. If symptoms occur, notify prescriber immediately, expect to discontinue drug, and provide supportive care.

- Monitor patient's liver function. If jaundice or signs and symptoms of liver dysfunction occur, notify prescriber and expect drug to be discontinued.
- Watch for hypersensitivity reactions, especially in patients with aspirin sensitivity, because drug contains the yellow dye tartrazine.
- Check patient's serum sodium level, as ordered, because drug may cause hyponatremia, especially in elderly patients, patients taking diuretics, and patients who are volume-depleted.
- Expect to taper drug when no longer needed, as ordered, to minimize adverse reactions.

## **PATIENT TEACHING**

- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.
- Caution patient against stopping drug abruptly because serious adverse effects may result.
- Instruct patient to alert all prescribers that he takes milnacipran.
- Tell patient to have his blood pressure monitored regularly throughout milnacipran therapy.
- Advise patient to avoid activities, such as driving, that require alertness until the CNS effects of milnacipran are known.
- Caution patient to avoid aspirin and NSAIDs, if possible, while taking milnacipran.
- Instruct patient to notify prescriber if any persistent, severe, or unusual signs or symptoms occur.

# milrinone lactate

**Primacor**

## Class and Category

*Pharmacologic class:* Phosphodiesterase 3 inhibitor

*Therapeutic class:* Inotropic

## Indications and Dosages

➤ *To provide short-term treatment of acute heart failure*

### I.V. INFUSION

**Adults.** *Loading:* 50 mcg/kg over 10 min (at least 0.375 mcg/kg/min). *Usual:* 0.375 to 0.75 mcg/kg/min as a continuous infusion. *Maximum:* 1.13 mg/kg daily.

***DOSAGE ADJUSTMENT*** Dosage adjusted according to cardiac output, pulmonary artery wedge pressure (PAWP), and clinical response. If creatinine clearance is 50 ml/min, infusion rate reduced to 0.43 mcg/kg/min; if 40 ml/min, infusion rate reduced to 0.38 mcg/kg/min; if 30 ml/min, infusion rate reduced to 0.33 mcg/kg/min; if 20 ml/min, to 0.28 mcg/kg/min; if 10 ml/min, to 0.23 mcg/kg/min; and if 5 ml/min, to 0.2 mcg/kg/min.

Route	Onset	Peak	Duration
I.V.	5-15 min	Unknown	3-6 hr

## Incompatibilities

Don't administer milrinone through same I.V. line as furosemide because precipitate will form. Don't add other drugs to premixed milrinone flexible containers.

## Contraindications

Hypersensitivity to milrinone or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Headache, tremor

**CV:** Angina, **hypotension**, **supraventricular arrhythmias**, **torsades de pointes**, **ventricular ectopic activity** **ventricular fibrillation and tachycardia**, **torsades de pointes**

**GI:** Liver function test abnormalities

**HEME:** **Thrombocytopenia**

**RESP:** **Bronchospasm**

**SKIN:** Rash

**Other:** **Anaphylactic shock**, **hypokalemia**, infusion-site reactions (pain, redness, swelling)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### Mechanism of Action

An inotropic drug, milrinone increases the force of myocardial contraction—and cardiac output—by blocking the enzyme phosphodiesterase. Normally, this enzyme is activated by hormones binding to cell membrane receptors. As shown below left, phosphodiesterase normally degrades intracellular cAMP, which restricts calcium movement into myocardial cells. By inhibiting phosphodiesterase, as shown below right, milrinone slows the rate of cAMP degradation, increasing the intracellular cAMP level and the amount of calcium that enters myocardial cells. In blood vessels, increased cAMP causes smooth-muscle relaxation, which improves cardiac output by reducing preload and afterload.

Description

## Nursing Considerations

- Make sure ECG equipment is available for continuous monitoring during milrinone therapy.
- Discard drug if it's discolored or contains particles.
- For loading dose, infuse undiluted drug directly into I.V. line with compatible infusing solution. For continuous infusion, dilute drug with half-normal (0.45) saline solution, normal saline solution, or D<sub>5</sub>W. Dilution isn't needed when using premixed milrinone flexible containers.
- Give loading dose using a controlled-rate infusion device. For continuous infusion, use a calibrated electronic infusion device.
- Check platelet count before and periodically during infusion, as ordered. Expect to discontinue drug if platelet count falls below 150,000/mm<sup>3</sup>.
- Monitor blood pressure, cardiac output, fluid status, heart rate, pulmonary artery wedge pressure, and weight during therapy to determine drug effectiveness.
- Monitor liver and renal function test results and serum electrolyte levels. Notify prescriber of abnormalities.
- If severe hypotension develops, notify prescriber at once and expect to stop drug.

- Expect patient to receive digoxin before starting milrinone, which can increase ventricular response rate.

## PATIENT TEACHING

- Reassure patient that he will be monitored constantly during therapy.

## minocycline hydrochloride

**CoreMino, Dynacin, Minocin, Minolira, Novo-Minocycline (CAN), Solodyn, Ximino**

## Class and Category

*Pharmacologic class:* Tetracycline

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat infections as follows: Bartonellosis due to Bartonella bacilliformis; Brucellosis due to Brucella species; Campylobacter fetus infections caused by Campylobacter fetus ; Chancroid caused by Haemophilus ducreyi; Cholera caused by Vibrio cholerae; Granuloma inguinale caused by Kebsiella granulomatis; Inclusion conjunctivitis caused by Chlamydia trachomatis; Lymphogranuloma venereum caused by Chlamydia trachomatis; Plague caused by Yersinia pestis; Psittacosis due to Chlamydophila*

*psittaci ; Relapsing fever due to Borrelia recurrentis; Respiratory tract infections caused by Mycoplasma pneumoniae; Rocky Mountain spotted fever, typhus fever and the typhus group, q fever, rickettsialpox and tick fevers caused by rickettsiae; Trachoma caused by Chlamydia trachomatis; or Tularemia due to Francisella tularensis; other gram-negative infections caused by Acinetobacter species, Enterobacter aerogenes, Escherichia coli, respiratory tract infections caused by Haemophilus influenzae, or respiratory tract and urinary tract infections caused by Klebsiella species; other gram-positive infections such as skin and skin structure infections caused by Staphylococcus aureus or upper respiratory tract infections caused by Streptococcus pneumoniae; and infections when penicillin is contraindicated such as Actinomycosis caused by Actinomyces israelii, Anthrax due to Bacillus anthracis, Listeriosis due to Listeria monocytogenes, Vincent's infection caused by Fusobacterium fusiforme, or Yaws caused by Treponema pallidum subspecies pertenue*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** *Initial:* 200 mg. *Maintenance:* 100 mg every 12 hr. Or 100 to 200 mg initially, followed by 50 mg every 6 hr.

**Children over age 8.** *Initial:* 4 mg/kg. *Maintenance:* 2 mg/kg every 12 hr. *Maximum:* 200 mg as initial dose; 100 mg/dose for maintenance.

## **I.V. INFUSION**

**Adults and adolescents.** *Initial:* 200 mg infused over 60 min. *Maintenance:* 100 mg every 12 hr. *Maximum:* 400 mg

daily.

**Children over age 8.** *Initial:* 4 mg/kg. *Maintenance:* 2 mg/kg every 12 hr. *Maximum:* 200 mg for initial dose; 100 mg/dose for maintenance dose; and 400 mg total daily dose.

***DOSAGE ADJUSTMENT*** For patient with renal impairment, dosage decreased or dosage interval increased; dosage not to exceed 200 mg daily.

## **E.R. TABLETS**

**Adults and adolescents age 12 and over.** 1 mg/kg once daily for 12 weeks.

***DOSAGE ADJUSTMENT*** For patient with renal impairment, dosage reduced or time interval between doses extended.

- *To treat uncomplicated gonorrhea from Neisseria gonorrhoeae in nonpregnant patients allergic to penicillin*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** *Initial:* 200 mg. *Maintenance:* 100 mg every 12 hr for at least 4 days.

- *To treat uncomplicated gonococcal urethritis in men allergic to penicillin*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 100 mg every 12 hr for 5 days.

- *To treat asymptomatic meningococcal carriers with Neisseria meningitidis in nasopharynx*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults and adolescents.** 100 mg every 12 hr for 5 days.

**Children over age 8.** *Initial:* 4 mg/kg. *Maintenance:* 2 mg/kg every 12 hr for 5 days.

- *To treat infections caused by Mycobacterium marinum*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 100 mg every 12 hr for 6 to 8 wk.

- *To treat uncomplicated nongonococcal endocervical, rectal, or urethral infection caused by Chlamydia trachomatis or Ureaplasma urealyticum*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 100 mg every 12 hr for at least 7 days.

- *To treat syphilis caused by Treponema pallidum in patients allergic to penicillin*

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** *Initial:* 200 mg, followed by 100 mg every 12 hr for 10 to 15 days.

- *To treat acne including inflammatory, nonnodular, moderate to severe*

## **CAPSULES, TABLETS**

**Adults and children 8 years and older.** 50 to 100 mg twice daily for up to 12 wks.

## **E.R. CAPSULES (XIMINO)**

**Adults and children 12 years and older.** 1 mg/kg/dose once daily for 12 wks

## **E.R. TABLETS (MINOLIRA)**

**Adults weighing 126 to 136 kg (277 to 299 lb)** 135 mg once daily.

**Adults weighing 90 to 125 kg (198 to 275 lb).** 105 mg once daily.

**Adults weighing 60 to 89 kg (132 to 196 lb).** 67.5 mg (one-half of the 135 mg tablet) once daily.

**Adults weighing 45 to 59 kg (99 to 130 lb).** 52.5 mg (one half of the 105 mg tablet) once daily

## **E.R. TABLET (COREMINO, SOLODYN)**

**Adults weighing 126 to 136 kg (277 to 299 lb).** 135 mg once daily.

**Adults weighing 111 to 125 kg (244 to 275 lb).** 115 mg once daily.

**Adults weighing 97 to 110 kg (213 to 242 lb).** 105 mg once daily.

**Adults weighing 85 to 96 kg (187 to 211 lb).** 90 mg once daily.

**Adults weighing 72 to 84 kg (158 to 184 lb).** 80 mg once daily.

**Adults weighing 60 to 71 kg (132 to 156 lb).** 65 mg once daily.

**Adults weighing 50 to 59 kg (110 to 130 lb).** 55 mg once daily.

**Adults weighing 45 to 49 kg (99 to 108 lb).** 45 mg once daily.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	Unknown	2-4 hr	6-12 hr
I.V.	Unknown	Unknown	6-12 hr

## **Mechanism of Action**

Inhibits bacterial protein synthesis by competitively binding to the 30S ribosomal subunit of the mRNA-ribosome complex of certain organisms.

## Incompatibilities

Don't mix minocycline in same syringe with solution that contains calcium because precipitate will form.

## Contraindications

*US:* Hypersensitivity to minocycline, other tetracyclines, or their components; *Canada in addition to US:* Breastfeeding children under age 12, complete renal failure, myasthenia gravis, pregnancy, severe liver disease

## Interactions

### DRUGS

*aluminum-, calcium-, or magnesium-containing antacids; calcium supplements; choline and magnesium salicylates; iron-containing preparations; magnesium-containing laxatives; sodium bicarbonate:* Possibly formation of nonabsorbable complex, impaired minocycline absorption

*atazanavir:* Possibly decreased serum concentration of atazanavir

*BCG (immunization or intravesical):* Possibly decreased effectiveness of BCG

*bile acid sequestrants, calcium salts:* Decreased minocycline absorption

*bismuth subsalicylate:* Possibly decreased serum concentration of minocycline

*cholera or typhoid vaccines:* Possibly diminished effectiveness of vaccines

*CNS depressants*: Possibly enhanced CNS depressant effect  
*lactobacillus and estriol*: Possibly diminished effectiveness of these products  
*lanthanum*: Possible decreased effectiveness of minocycline  
*mecamylamine*: Possibly enhanced neuromuscular-blocking effect of mecamylamine  
*methoxyflurane*: Increased risk of nephrotoxicity  
*mipomersen*: Possibly enhanced hepatotoxicity of mipomersen  
*multivitamins/minerals*: Possibly decreased concentration of minocycline  
*neuromuscular blocking agents*: Enhanced neuromuscular-blocking effect of these agents  
*penicillin*: Interference with bactericidal action of penicillin  
*quinapril*: Possibly decreased effectiveness of minocycline  
*retinoic acid derivatives*: Possibly enhanced adverse effects of these drugs  
*sucralfate, zinc salts*: Possibly decreased absorption of minocycline  
*sucroferric oxyhydroxide*: Possibly decreased serum concentration of minocycline  
*vitamin K antagonists*: Possibly enhanced anticoagulant effect of vitamin K antagonists

## Adverse Reactions

**CNS**: Dizziness, fever, headache, **intracranial hypertension**, light-headedness, unsteadiness, vertigo

**CV**: **Myocarditis**, **pericarditis**

**EENT**: Blurred vision, darkened or discolored tongue, glossitis, papilledema, tooth discoloration, vision changes

**ENDO**: Thyroid function abnormality, **thyroid cancer**

**GI:** Abdominal cramps or pain, anorexia, diarrhea, dysphagia, enterocolitis, esophageal irritation and ulceration, **hepatitis, hepatotoxicity, jaundice,** indigestion, nausea, **pancreatitis, pseudomembranous colitis,** vomiting

**GU:** Genital candidiasis, **nephritis, nephrotoxicity**

**HEME:** Eosinophilia, **hemolytic anemia, neutropenia, thrombocytopenia, thrombocytopenic purpura**

**MS:** Arthralgia, myopathy (transient)

**RESP:** **Pneumonitis, pulmonary infiltrates**

**SKIN:** **Erythema multiforme, exfoliative dermatitis,** Brown pigmentation of skin and mucous membranes, **erythema multiforme, exfoliative dermatitis,** erythematous and maculopapular rash, onycholysis, photosensitivity, pruritus, purpura (anaphylactoid), rash, **Stevens-Johnson syndrome,** urticaria

**Other:** **Anaphylaxis, angioedema,** serum sickness-like reaction, systemic lupus erythematosus exacerbation

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm as it crosses the placental barrier such as discoloration of teeth.
- Like other tetracyclines, rare reports of congenital anomalies including limb reduction have been reported.
- Drug is not recommended for use during pregnancy.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use minocycline cautiously in patients with hepatic or renal dysfunction and in those taking other hepatotoxic drugs because drug may cause nephrotoxicity or hepatotoxicity.
- Use minocycline cautiously in patients with a history of predisposition to oral candidiasis, because safety and effectiveness of drug have not been established for treatment of periodontitis in patients with coexistent oral candidiasis.

**WARNING** Notify prescriber if patient is breastfeeding because drug appears in breast milk and may have toxic effects.

- Monitor blood, hepatic, and renal tests before and during long-term therapy.
- Shake oral suspension well before use.
- Prepare drug for I.V. use by reconstituting each 100-mg vial with 5 to 10 ml sterile water for injection. Further dilute in 500 to 1,000 ml normal saline solution, D<sub>5</sub>W, dextrose 5% in normal saline solution, or Ringer's or lactated Ringer's solution. Administer final dilution immediately, but avoid rapid administration.
- Store reconstituted drug for I.V. administration at room temperature and use within 24 hours.
- Assess patient for signs of superinfection; if signs appear, notify prescriber, discontinue minocycline, and start appropriate therapy, as ordered.
- Monitor patient for development of foul-smelling diarrhea, which suggests *Clostridium difficile*. If present, notify prescriber, obtain stool culture, and expect to withhold minocycline and provide supportive care, as indicated and ordered.
- Monitor PT in patient who also takes an anticoagulant during minocycline therapy.
- Monitor patient for signs and symptoms of thyroid cancer such as alteration in thyroid function or presence of nodule in patients receiving minocycline therapy over prolonged periods.

**WARNING** Monitor patient for blurred vision or headache because benign intracranial hypertension has occurred with the use of minocycline. If present, notify prescriber and expect drug to be discontinued. Know that although intracranial hypertension usually resolves after drug is discontinued, permanent visual loss can occur. Expect patient with suspected intracranial hypertension to undergo a prompt ophthalmologic evaluation and be monitored until vision is stabilized as intracranial pressure can remain elevated for weeks after drug is discontinued.

## **PATIENT TEACHING**

- Instruct patient to shake oral suspension well and to use calibrated measuring device.
- Advise patient to take minocycline with a full glass of water, with food or milk, and in an upright position to minimize esophageal and GI irritation.
- Direct patient to take a missed dose as soon as he remembers unless it's nearly time for the next dose. Caution against double-dosing.
- Instruct patient not to take minocycline within 2 hours of an antacid or 3 hours of an iron preparation.
- Urge patient to complete full course of treatment even if he feels better before finishing.
- Instruct patient to notify prescriber if no improvement occurs in a few days.
- Advise patient to avoid prolonged exposure to sun or sunlamps during therapy.
- Counsel female patient to avoid becoming pregnant because minocycline should be avoided, if possible, during tooth development (last half of gestation up to age 8).
- Instruct patient to notify prescriber immediately about blurred vision, dizziness, headache, known or suspected pregnancy, and unsteadiness.
- Explain that diarrhea may occur up to 2 months after completing therapy; urge patient to notify prescriber if it occurs.

# mipomersen sodium

**Kynamro**

## Class and Category

*Pharmacologic class:* Oligonucleotide

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *As adjunct to diet and lipid-lowering medications to reduce apolipoprotein B (apo B), low density lipoprotein-cholesterol (LDL-C), non-high density lipoprotein-cholesterol (non-HDL-C), and total cholesterol (TC) in patients with homozygous familial hypercholesterolemia*

## SUBCUTANEOUS INJECTION

**Adults.** 200 mg once weekly.

## Mechanism of Action

Targets human messenger ribonucleic acid (mRNA) for apo B-100, the principal apolipoprotein of low density lipoproteins (LDL) and its metabolic precursor, very low density lipoprotein (VLDL). Once targeted, translation of the apo B-100 protein is inhibited, resulting in lower lipid levels.

## Contraindications

Active liver disease, hypersensitivity to mipomersen or its components, moderate or severe hepatic impairment, unexplained persistent elevations of serum transaminases

## Interactions

### DRUGS

*other hepatotoxic drugs such as acetaminophen, amiodarone, isotretinoin, methotrexate, tamoxifen, tetracyclines:* Increased risk of hepatotoxicity and hepatic steatosis

### ACTIVITIES

*alcohol use:* Possibly increased risk of hepatic steatosis

## Adverse Reactions

**CNS:** Chills, fatigue, fever, headache, insomnia

**CV:** Angina pectoris, hypertension, palpitations, peripheral edema

**GI:** Abdominal pain, elevated liver enzymes, hepatic steatosis, **hepatotoxicity**, nausea, transaminase elevations, vomiting

**HEME:** **Alterations in platelet count, idiopathic thrombocytopenic purpura**

**MS:** Extremity or musculoskeletal pain

**SKIN:** Rash, urticaria

**Other:** **Angioedema**, flu-like symptoms; injection-site reactions such as discoloration, erythema, hematoma, local swelling, pain, pruritus, tenderness

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potentially serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Know that because mipomersen increases risk of hepatotoxicity, the drug can only be administered through the Kynamro REMS program.
- Determine that patient has had alkaline phosphatase, transaminase levels, and total bilirubin measured prior to initiating mipomersen therapy to rule out liver impairment.
- Administer mipomersen only by subcutaneous route. Never administer drug intramuscularly or intravenously.
- Know that each vial or prefilled syringe contains 200 mg of mipomersen in 1 ml of solution and is intended for single dose only.
- Remove vial or prefilled syringe from refrigerated storage and allow to reach room temperature for at least 30 minutes prior to administration.
- Give injection on the same day every week. If a dose is missed, give injection at least 3 days from the next weekly dose. Administer injection into the patient's abdomen, outer region of the upper arm, or thigh region. Never inject drug in areas of active skin disease or injury such as inflammation, skin infections or rashes, sunburns, or psoriasis areas that are active. Also, do not inject drug into scar areas or tattooed skin.
- Be aware that transaminase levels should be measured monthly for first year of therapy and then every 3 months thereafter. If transaminase values are equal to or greater than three times upper limit normal but less than five times upper limit normal, expect to confirm elevation with a repeat measurement within 1 week. If confirmed, expect dosage to be withheld and additional liver-related tests done, such as measurement of

alkaline phosphatase, total bilirubin, and INR. If transaminase elevations are five times or greater, expect drug to be withheld immediately and additional liver-related tests performed. Once transaminases level are less than three times upper limit normal, know that drug may be resumed and liver function assessed more frequently. If transaminase elevations are accompanied by signs of abnormal liver function such as abdominal pain, doubling or greater bilirubin values of upper limit normal, fever, flu-like symptoms, jaundice, lethargy, nausea, or vomiting, expect drug to be discontinued.

## PATIENT TEACHING

- Remind patient of importance of adhering to the low-fat diet prescribed, as mipomersen therapy is not a replacement for dietary control of fat in her diet.
- Teach patient how to administer a subcutaneous injection and where on body to administer drug. Remind patient to rotate sites and to discard syringe and needle appropriately.
- Warn patient that flu-like symptoms may occur within 2 days of injection but does not occur with all injections. If significant, tell patient to notify prescriber.
- Tell patient to inform all prescribers about mipomersen therapy because of potential drug interactions.
- Review signs and symptoms of liver impairment and emphasize importance of reporting such to prescriber, especially stomach pain that gets worse, does not go away, or changes. Inform patient of need for blood tests to monitor her liver function and importance of compliance with test schedule.

**WARNING** Instruct patient not to consume more than one alcoholic beverage daily.

- Urge patient to seek immediate emergency care if hypersensitivity reactions occur and to discontinue taking mipomersen if instructed to do so.

**mirabegron**

# Myrbetriq

## Class and Category

*Pharmacologic class:* Beta-3 adrenergic agonist

*Therapeutic class:* Bladder antispasmodic

## Indications and Dosages

- *To treat overactive bladder with symptoms of urge urinary incontinence, urgency, and urinary frequency as monotherapy or in combination with solifenacin succinate*

### E.R. TABLETS

**Adults.** *Initially:* 25 mg once daily, increased as needed to 50 mg once daily (after 4 to 8 wk if used with solifenacin succinate).

***DOSAGE ADJUSTMENT*** For patients with severe hepatic or renal impairment, dosage should not exceed 25 mg once daily.

## Mechanism of Action

Relaxes the detrusor smooth muscle during the storage phase of the urinary bladder fill-void cycle by activating the beta-3 adrenergic receptor, which increases bladder capacity. With increased bladder capacity, urge sensation is decreased, which in turn decreases urinary frequency.

## Contraindications

Hypersensitivity to mirabegron or its components

# Interactions

## DRUGS

*CYP2D6 substrates such as desipramine, flecainide, metoprolol, propafenone, thioridazine:* Increased blood levels of these drugs

*digoxin:* Increased risk of digoxin toxicity

*warfarin:* Possibly changes in INR and prothrombin time with multiple doses of warfarin

## Adverse Reactions

**CNS:** Anxiety, confusion, dizziness, fatigue, hallucinations, headache, insomnia

**CV:** **Atrial fibrillation**, hypertension, elevated LDH levels, palpitations, tachycardia

**EENT:** Dry mouth, glaucoma, nasopharyngitis, rhinitis, sinusitis

**GI:** Abdominal distention or pain, constipation, diarrhea, dyspepsia, elevated liver enzymes, gastritis, nausea

**GU:** Bladder pain, cystitis, nephrolithiasis, **prostate cancer**, urinary retention, UTI, vaginal infections, vulvovaginal pruritis

**MS:** Arthralgia, back pain

**SKIN:** Pruritis, rash, **Stevens-Johnson syndrome**

**Other:** **Angioedema**, influenza-like infection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that mirabegron should not be given to patients with severe uncontrolled hypertension (defined as systolic blood pressure 180 mm Hg or higher and/or diastolic blood pressure 110 mm Hg or higher) because drug can increase blood pressure. Monitor patient's blood pressure regularly and report persistent or significant increases to prescriber.
- Be aware that mirabegron should not be given to patients with end stage renal disease or in patients with severe hepatic impairment because drug has not been studied in these conditions, and adverse effects are unknown.
- Use mirabegron cautiously in patients with bladder outlet obstruction and in patients taking antimuscarinic drugs for the treatment of this condition because the drug may cause urinary retention.

**WARNING** Monitor patient closely for angioedema of the face, larynx, lips, and tongue, which may occur as soon as the first dose or hours after the first dose or after multiple doses. Be prepared to administer emergency treatment for life-threatening upper airway swelling, as ordered, and maintain a patent airway. Notify prescriber and expect drug to be discontinued.

- Keep in mind that it may take up to 8 weeks to observe efficacy with 25 mg strength

## PATIENT TEACHING

- Instruct patient to take mirabegron with water and to swallow tablet whole. Caution patient not to chew, crush, or divide tablets prior to ingesting.

- Warn patient that drug may increase blood pressure. Encourage patient to have his blood pressure checked regularly, especially if he has hypertension.
- Review common adverse effects of drug with patient. Tell patient to notify prescriber if he experiences a decrease in urinary output despite a normal intake. Also remind patient that drug may cause itching, rapid heartbeat, rash, or urinary tract infections and to alert prescriber if present.

## mirtazapine

### Remeron, Remeron SolTab

## Class and Category

*Pharmacologic class:* Tetracyclic antidepressant

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat major depression*

### ORAL DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 15 mg daily, preferably at bedtime.

Increased as needed and tolerated at 1- to 2-wk intervals.

*Maximum:* 45 mg daily.

***DOSAGE ADJUSTMENT*** For the elderly and patients with hepatic or renal impairment, dosage may need to be reduced

Route	Onset	Peak	Duration
P.O.	1-2 wk	6 wk or longer	Unknown

## Mechanism of Action

May inhibit neuronal reuptake of norepinephrine and serotonin. By doing so, this tetracyclic antidepressant increases the action of these neurotransmitters in nerve cells. Increased neuronal serotonin and norepinephrine levels may elevate mood.

## Contraindications

Hypersensitivity to mirtazapine or its components; use within 14 days of an MAO inhibitor, including I.V. methylene blue and linezolid

## Interactions

### DRUGS

*anxiolytics, hypnotics, other CNS depressants (including sedatives):* Increased CNS depression

*CYP3A4 inducers such as carbamazepine, phenytoin, rifampicin:* Decreased mirtazapine effects and effectiveness

*CYP3A4 inhibitors such as azole antifungals, cimetidine, CYP3A4 inhibitors, erythromycin, HIV protease inhibitors, ketoconazole, nefazodone:* Increased serum mirtazapine effects and risk of adverse reactions

*MAO inhibitors, including I.V. methylene blue and linezolid; other serotonergic drugs:* Possibly hyperpyrexia, hypertension, seizures, and serotonin syndrome

*QTc-prolonging drugs:* Increased risk of QT prolongation and/or ventricular arrhythmias such as Torsades de Pointes

*warfarin:* Possible increase in INR

### ACTIVITIES

*alcohol use:* Increased CNS depression

## Adverse Reactions

**CNS:** Agitation, akathisia, amnesia, anxiety, apathy, asthenia, ataxia, **cerebral ischemia**, chills, confusion, delirium, delusions, depersonalization, depression, dizziness, dream disturbances, drowsiness, dyskinesia, dystonia, emotional lability, euphoria, extrapyramidal reactions, fever, hallucinations, hostility, hyperkinesia, hyperreflexia, hypoaesthesia, hypokinesia, lack of coordination, malaise, mania, migraine headache, **neuroleptic malignant syndrome-like reactions**, neurosis, paranoia, paresthesia, psychomotor restlessness, **seizures**, **serotonin syndrome**, somnambulism (ambulation and other complex behaviors out of bed), somnolence, syncope, tremor, vertigo

**CV:** Angina, **bradycardia**, edema, hypercholesterolemia, hypertension, hypertriglyceridemia, **hypotension**, **MI**, orthostatic hypotension, peripheral edema, **PVCs**, **torsades de pointes**, vasodilation, **ventricular arrhythmia**

**EENT:** Accommodation disturbances, conjunctivitis, dry mouth, earache, epistaxis, eye pain, gingival bleeding, glaucoma, glossitis, hearing loss, hyperacusis, keratoconjunctivitis, lacrimation, pharyngitis, sinusitis, stomatitis

**ENDO:** Breast pain, galactorrhea, gynecomastia, hyperprolactinemia

**GI:** Abdominal distention and pain, anorexia, cholecystitis, colitis, constipation, elevated ALT level, eructation, increased appetite, nausea, thirst, vomiting

**GU:** Amenorrhea, cystitis, dysmenorrhea, dysuria, hematuria, impotence, increased libido, leukorrhea, renal calculi, urinary frequency and incontinence, urine retention, UTI, vaginitis

**HEME:** Agranulocytosis, neutropenia

**MS:** Arthralgia, back pain, dysarthria, elevated creatine kinase blood level, muscle twitching, myalgia, myasthenia, neck pain and rigidity, rhabdomyolysis

**RESP:** Asthma, bronchitis, cough, dyspnea, pneumonia

**SKIN:** Acne, alopecia, bullous dermatitis, dry skin, erythema multiforme, exfoliative dermatitis, photosensitivity, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Angioedema, dehydration, flu-like symptoms, herpes simplex, hyponatremia, weight change

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use mirtazapine cautiously in elderly patients and in those receiving concurrent medication known to cause hyponatremia because drug may lower the serum sodium level in these patients.
- Administer mirtazapine before bedtime.
- Expect disintegrating tablet to dissolve on patient's tongue within 30 seconds.

**WARNING** Don't give drug within 14 days of an MAO inhibitor or concurrent therapy with serotonin-precursors such as L-tryptophan and oxitriptan to avoid serious, possibly fatal, serotonin syndrome reaction. Use drug cautiously in patients receiving other serotonergic drugs such as lithium, St. John's wort, tramadol, triptans, and most tricyclic antidepressants because of increased risk for serotonin syndrome. Know that both disorders can occur as an adverse drug reaction to mirtazapine therapy without the concomitant use of other drugs. Monitor patient closely for signs and symptoms of serotonin syndrome such as alteration in vital signs, gastrointestinal symptoms, mental status changes, or neuromuscular abnormalities. Its most severe form resembles neuroleptic malignant syndrome and presents with autonomic instability with possible rapid changes in vital signs, hyperthermia, mental status changes, and muscle rigidity. If any of these symptoms occur, notify prescriber immediately, provide supportive care, as ordered, and expect mirtazapine to be discontinued.

- Monitor patient closely, especially during the first few weeks of therapy, for the development of akathisia, an unpleasant or distressing restlessness and need to move, often accompanied by an inability to sit or stand still. Notify prescriber, if present, and know that increasing the dose may worsen patient's condition.
- Watch closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may briefly worsen.
- Monitor patient closely for infection (fever, pharyngitis, stomatitis), which may be linked to a low WBC count. If these signs occur, notify prescriber and expect to stop drug.
- Expect mirtazapine therapy to last 6 months or longer for acute depression.
- Be aware that mirtazapine therapy should not be discontinued abruptly because adverse reactions may occur.

## PATIENT TEACHING

- Instruct patient not to swallow disintegrating tablet. Tell him to hold tablet on tongue and let it dissolve. Inform him that tablet will dissolve within 30 seconds.
- Inform phenylketonuric patient that mirtazapine disintegrating tablets contain phenylalanine 2.6 mg per 15-mg tablet, 5.2 mg per 30-mg tablet, and 7.8 mg per 45-mg tablet.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Instruct patient to avoid alcohol and other CNS depressants during therapy and for up to 7 days after drug is discontinued.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Direct patient to change position slowly to minimize the effects of orthostatic hypotension.
- Instruct patient to notify prescriber at once about chills, fever, mouth irritation, sore throat, and other signs of infection.
- Encourage patient to visit prescriber regularly during therapy to monitor progress.
- Caution patient not to discontinue mirtazapine therapy abruptly.

## mitoxantrone hydrochloride

### Class and Category

*Pharmacologic class:* Anthracenedione

*Therapeutic class:* Antineoplastic

### Indications and Dosages

- *To reduce neurologic disability and frequency of relapses in patients with secondary (chronic) progressive, progressive relapsing, or worsening relapsing-remitting multiple sclerosis (patients whose neurologic status is significantly abnormal between relapses)*

## **I.V. INFUSION**

**Adults.** 12 mg/m<sup>2</sup> over 5 to 15 min every 3 mo. *Maximum:* Cumulative dose of 140 mg/m<sup>2</sup> or more.

- *As adjunct to treat pain related to advanced hormone-refractory prostate cancer*

## **I.V. INFUSION**

**Adults.** 12 to 14 mg/m<sup>2</sup> over 5 to 15 min every 21 days.

- *As adjunct to treat acute nonlymphocytic leukemia (ANLL)*

## **I.V. INFUSION**

**Adults.** *Initial:* 12 mg/m<sup>2</sup> over 5 to 15 min on days 1 to 3 with 100 mg/m<sup>2</sup> of cytarabine as a continuous 24-hr infusion on days 1 to 7. If patient's antileukemic response is inadequate or incomplete, second induction course is given at same dosage but only for 2 days with mitoxantrone and 5 days for cytarabine.

## **Mechanism of Action**

Binds to DNA, causing cross-linkage and strand breakage, interfering with RNA synthesis, and inhibiting topoisomerase II, an enzyme that uncoils and repairs damaged DNA. Mitoxantrone produces a cytocidal effect on proliferating and nonproliferating cells and doesn't appear

to be cell-cycle specific. It's known to inhibit B-cell, T-cell, and macrophage proliferation and impair antigen function.

## Incompatibilities

Don't mix mitoxantrone in the same infusion as heparin (because a precipitate may form); don't mix with any other drugs.

## Contraindications

Hypersensitivity to mitoxantrone or its components

## Interactions

### DRUGS

*vaccines, killed virus*: Decreased antibody response to vaccine

*vaccines, live virus*: Increased risk of replication of and adverse effects of vaccine virus, decreased antibody response to vaccine

## Adverse Reactions

**CNS**: Headache, **seizures**

**CV**: **Arrhythmias**, **cardiotoxicity**, chest pain, **congestive heart failure**, decreased left ventricular ejection fraction, **ECG changes**

**EENT**: Blue-colored cornea, conjunctivitis, mucositis, stomatitis

**GI**: Abdominal pain, diarrhea, elevated liver enzymes, **GI bleeding**, jaundice, nausea, vomiting

**GU**: Blue-green urine, **renal failure**

**HEME:** Acute myelogenous leukemia, leukopenia, other leukemias, thrombocytopenia

**MS:** Myelodysplasia

**RESP:** Cough, dyspnea

**SKIN:** Alopecia, extravasation

**Other:** Anaphylaxis, hypersensitivity reactions, hyperuricemia, infection, infusion-site pain or redness

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- A negative pregnancy test must be obtained prior to each dose.
- Drug should not be given to pregnant women.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding should be discontinued prior to drug therapy.

### REPRODUCTION

- Women of childbearing age should use an effective form of contraception during drug therapy.
- If pregnancy occurs while taking drug, patient should notify prescriber immediately.

## Nursing Considerations

- Before mitoxantrone therapy and before each dose, expect patient to have an ECG and evaluation of left ventricular ejection fraction. Expect to obtain CBC with platelet count, and hematocrit and hemoglobin level(s). If

patient's left ventricular ejection fraction drops below normal, expect drug to be discontinued.

- Be aware that drug shouldn't be given to patient with multiple sclerosis whose neutrophil count is less than  $1,500/\text{mm}^3$  or who has a below-normal left ventricular ejection fraction.
- Check liver enzymes, as ordered, before each course of therapy. Expect that drug won't be given to multiple sclerosis patient with abnormal liver function.
- Assess patient for cardiac dysfunction throughout therapy. Watch for evidence of cardiotoxicity, such as arrhythmias and chest pain, in patient with heart disease. Risk increases when cumulative dose reaches  $140 \text{ mg}/\text{m}^2$  in cancer or  $100 \text{ mg}/\text{m}^2$  in multiple sclerosis. Notify prescriber of any significant changes, and expect drug to be discontinued. Be aware that congestive heart failure may occur months or years after drug has been discontinued.
- Anticipate obtaining pregnancy test before each course of therapy for women of childbearing age with multiple sclerosis.
- Follow facility policy for handling antineoplastics. Be aware that manufacturer recommends goggles, gloves, and a gown during drug preparation and delivery.
- Before infusing drug, dilute it in at least 50 ml of normal saline solution or D<sub>5</sub>W.

**WARNING** Know that drug shouldn't be given intrathecally because paralysis may occur.

- Know that if mitoxantrone solution contacts skin or mucosa, the area should be washed thoroughly with warm water. If it contacts eyes, irrigate them thoroughly with water or normal saline solution.
- Discard unused diluted solution because it contains no preservatives. After penetration of stopper, store undiluted drug for up to 7 days at room temperature or 14 days refrigerated. Avoid freezing drug.
- If extravasation occurs, stop infusion immediately and notify prescriber. Reinsert I.V. line in another vein and resume infusion. Although mitoxantrone is a nonvesicant, observe the extravasation site for signs of necrosis or phlebitis.
- Monitor patients with chickenpox or recent exposure and patients with herpes zoster for severe, generalized disease.

- Monitor blood uric acid level for hyperuricemia in patients with a history of gout or renal calculi. Expect to give allopurinol, as prescribed, to patients with leukemia or lymphoma and elevated blood uric acid level to prevent uric acid nephropathy.

**WARNING** Be aware that if severe or life-threatening nonhematologic or hematologic toxicity occurs during first induction course, the second course will probably be withheld until it resolves.

- Know that if patient develops thrombocytopenia, precautions should be taken per facility policy.
- Assess patient for evidence of infection, such as fever, if leukopenia occurs. Expect to obtain appropriate specimens for culture and sensitivity testing.
- Be aware that patients receiving mitoxantrone in combination with other antineoplastics or radiation therapy or who have multiple sclerosis are at risk for developing secondary leukemia, including acute myelogenous leukemia.

## **PATIENT TEACHING**

- Advise patient to complete dental work, if possible, before treatment begins or defer it until blood counts return to normal; drug may delay healing and cause gingival bleeding. Teach patient proper oral hygiene, and advise use of a toothbrush with soft bristles.
- Urge patient to drink plenty of fluid to increase urine output and uric acid excretion.
- Advise patient to contact prescriber immediately if GI upset occurs, but to continue taking drug unless otherwise directed.
- Emphasize the importance of complying with the dosage regimen and keeping follow-up medical and laboratory appointments.
- Explain that urine may appear blue-green for 24 hours after treatment and that the whites of the eyes may appear blue. Emphasize that these effects are temporary and harmless. Explain that hair loss is possible, but that hair should return after therapy ends.
- Caution patient not to receive immunizations unless approved by prescriber. Also, advise persons who live in same household as patient to

avoid receiving immunization with oral polio vaccine. Tell patient to avoid persons who recently received the oral polio vaccine or to wear a mask over his nose and mouth.

- Instruct patient to avoid persons with infections if bone marrow depression occurs. Advise patient to contact prescriber if chills, cough, fever, hoarseness, lower back or side pain, or difficult or painful urination occurs; these changes may signal an infection.
- Tell patient to contact prescriber immediately if he has black or tarry stools, unusual bleeding or bruising, blood in urine or stool, or pinpoint red spots on his skin.
- Urge patient not to touch his eyes or the inside of his nose unless he has just washed his hands.
- Emphasize the need to avoid accidental cuts, as from fingernail clippers or a razor, because of possible excessive bleeding or infection.
- Caution patient to avoid contact sports or activities that may cause bruising or injury.
- Urge patient to comply with yearly examinations after therapy ends to check for late-occurring drug-induced heart problems. Tell patient to report trouble breathing, swelling in ankles or legs, or a fast or uneven heartbeat even after drug has been discontinued.
- Warn women of childbearing age to avoid pregnancy but if pregnancy occurs to notify prescriber immediately.

## modafinil

### Provigil

## Class, Category, and Schedule

*Pharmacologic class:* Analeptic

*Therapeutic class:* CNS stimulant

*Controlled substance schedule:* IV

## Indications and Dosages

- *To improve daytime wakefulness in patients with narcolepsy, obstructive sleep apnea hypopnea syndrome, and shift work sleep disorder*

### **TABLETS**

**Adults.** 200 mg daily in the morning or 1 hr before starting work shift. *Maximum:* 400 mg daily.

***DOSAGE ADJUSTMENT*** For patients with severe hepatic impairment, dosage should be reduced by 50%.

## Mechanism of Action

May inhibit the release of gamma-aminobutyric acid (GABA), the most common inhibitory neurotransmitter, or CNS depressant, in the brain. Modafinil also increases the release of glutamate, an excitatory neurotransmitter, or CNS stimulant, in the hippocampus and thalamus. These two actions may improve wakefulness.

## Contraindications

Hypersensitivity to modafinil, armodafinil, or their components

## Interactions

### **DRUGS**

*CYP2C19 substrates such as clomipramine, diazepam, omeprazole, phenytoin, propranolol:* Increased systemic exposure of these drugs

*CYP3A4/5 substrates such as cyclosporine, midazolam, steroidal contraceptives, triazolam:* Decreased systemic exposure of these drugs with steroidal contraceptives continuing to have decreased effectiveness for one month after modafinil is discontinued

*MAO inhibitors:* Increased risk of adverse effects

*warfarin:* Possibly decreased warfarin metabolism and increased risk of bleeding

## Adverse Reactions

**CNS:** Aggressiveness, agitation, anxiety, confusion, delusions, depression, hallucinations, headache, insomnia, mania, nervousness, psychomotor hyperactivity, psychosis, **suicidal ideation**

**GI:** Nausea

**HEME:** **Agranulocytosis**

**SKIN:** Rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Anaphylaxis, angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS), infection, multiorgan hypersensitivity**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-404-4106.
- Drug may cause fetal harm such as intrauterine growth restriction and spontaneous abortion
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Keep in mind that modafinil shouldn't be given to patients with mitral valve prolapse syndrome or a history of left ventricular hypertrophy because drug may cause ischemic changes.
- Use cautiously in patients with recent MI or unstable angina because effect of drug is unknown in these disorders.
- Use cautiously in patients with a history of depression, mania, or psychosis because these conditions may worsen during therapy and may require modafinil to be stopped.

**WARNING** Monitor patient with a history of alcoholism, stimulant abuse, or other substance abuse for compliance with modafinil therapy. Observe for signs of abuse or misuse, including drug seeking behavior, frequent prescription refill requests, or increased frequency of dosing. Also watch for evidence of excessive modafinil dosage, including aggressiveness, anxiety, confusion, decreased prothrombin time, diarrhea, irritability, nausea, nervousness, palpitations, sleep disturbances, and tremor.

- Be aware that modafinil, like other CNS stimulants, may alter feelings, judgment mood, motor skills, perception, thinking, and signs that patient needs sleep.
- Know that if giving drug to patient with emotional instability, a history of psychosis, or psychological illness with psychotic features, be prepared to perform baseline behavioral assessments or frequent clinical observation.
- Stop drug at first sign of rash, and notify prescriber. Although rare, rash may indicate a potentially life-threatening event.
- Monitor patient for signs and symptoms of multisystem organ hypersensitivity, such as asthenia, fever, hematologic abnormalities, hepatitis, myocarditis, pruritus, rash, or any other serious abnormality,

because multiorgan hypersensitivity may vary in its presentation. Notify prescriber if suspected, and expect to discontinue drug and provide supportive care, as ordered.

- Watch closely for suicidal tendencies, especially in patients with a psychiatric history.

## **PATIENT TEACHING**

- Inform patient that modafinil can help, but not cure, narcolepsy and that drug's full effects may not be seen right away.
- Advise patient to avoid taking modafinil within 1 hour of eating because food may delay drug's absorption and onset of action. If he drinks grapefruit juice, encourage him to drink a consistent amount daily.
- Instruct patient to stop taking modafinil and to notify prescriber if he develops a fever, rash, or other serious effect.
- Urge patient to report anxiety, chest pain, depression, or evidence of mania or psychosis to prescriber.
- Inform patient that drug can affect concentration and function and can hide signs of fatigue. Urge him not to drive or perform activities that require mental alertness until full CNS effects are known.
- Advise patient to avoid alcohol while taking modafinil.
- Encourage a regular sleeping pattern.
- Caution patient to avoid excessive intake of beverages, foods, and OTC drugs that contain caffeine because caffeine may lead to increased CNS stimulation.
- Inform female patient that modafinil can decrease the effectiveness of certain contraceptives, including birth control pills and implantable hormonal contraceptives. If she uses such contraceptives, urge her to use an alternate birth control method during modafinil therapy and for up to 1 month after she stops taking the drug.
- Advise patient to keep follow-up appointments with prescriber so that her progress can be monitored.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including suicidal tendencies, especially if patient has a psychiatric history.

# **mometasone furoate**

**Asmanex HFA, Asmanex Twisthaler**

# **mometasone furoate monohydrate**

**Nasonex**

## **Class and Category**

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Anti-inflammatory

## **Indications and Dosages**

- *To manage symptoms of seasonal or allergic rhinitis*

### **NASAL SPRAY (NASONEX)**

**Adults and children 12 years and over.** 100 mcg (2 sprays) in each nostril once daily.

**Children ages 2 to 11.** 50 mcg (1 spray) in each nostril once daily.

- *To prevent seasonal allergic rhinitis*

### **NASAL SPRAY (NASONEX)**

**Adults and adolescents 12 years and over.** 100 mcg (2 sprays) in each nostril once daily, started 2 to 4 wk prior to anticipated start of pollen season, if known.

- *To treat nasal polyps*

## **NASAL SPRAY (NASONEX)**

**Adults.** 100 mcg (2 sprays) in each nostril once or twice daily.

- *To maintain asthma control*

## **ORAL INHALATION (ASMANEX TWISTHALER)**

**Adults and children age 12 and over who have been taking bronchodilators alone or inhaled corticosteroids.** *Initial:* 220 mcg (1 inhalation) once daily in evening. *Maximum:* 440 mcg (2 inhalations) daily given as 220 mcg (1 inhalation) twice daily or 440 mcg (1 inhalation) once daily.

**Adults and children age 12 and over who have taken oral corticosteroids.** 440 mcg (2 inhalations) twice daily. **Children ages 4 to 11.** 110 mcg (1 inhalation) once daily in evening.

## **ORAL INHALATION (ASMANEX HFA)**

**Adults and children age 12 and over not taking an inhaled corticosteroid.** *Initial:* Using a 100 mcg inhaler, 2 inhalations twice daily, increased, as needed, after 2 wks. *Maximum:* Using a 200 mcg inhaler, two inhalations twice daily for maximum dosage of 800 mcg/day.

**Adults and children age 12 and over taking oral corticosteroid therapy.**

*Initial:* Using a 200 mcg inhaler, 2 inhalations twice daily, increased, as needed after 2 wks. *Maximum:* Using a 200 mcg inhaler, two inhalations twice daily for maximum dosage of 800 mcg/day.

**Children age 5 to less than 12 years.** Using a 50 mcg inhaler, two inhalations twice daily. *Maximum:* 200 mcg

daily.

## Mechanism of Action

Inhibits the activity of cells and mediators active in the inflammatory response, possibly by decreasing influx of inflammatory cells into nasal passages and thereby decreasing nasal inflammation.

Inflammation is a key component in asthma pathophysiology. Decreasing the inflammatory response in lung tissue helps to relieve asthma symptoms.

## Contraindications

*For all forms:* Hypersensitivity to mometasone or its components; *For Asmanex Twisthaler:* Hypersensitivity to milk proteins, status asthmaticus or other asthma episodes that require emergency care; *For Asmanex HFA:* Status asthmaticus or other asthma episodes that require emergency care

## Interactions

### DRUGS

*strong CYP4503A4 inhibitors such as atazanavir, clarithromycin, cobicistat-containing products, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, telithromycin:* Increased plasma mometasone levels leading to possible increased adverse reactions

## Adverse Reactions

**CNS:** Headache

**CV:** Chest pain

**EENT:** Blurred vision, cataracts, conjunctivitis, dry mouth, earache, epistaxis, glaucoma, nasal irritation, nasopharyngitis, oral and pharyngeal candidiasis, otitis media, pharyngitis, rhinitis, sinusitis, throat tightness, unpleasant taste

**ENDO:** **Adrenal insufficiency**, growth suppression

**GI:** Diarrhea, dyspepsia, nausea, vomiting

**GU:** Dysmenorrhea

**MS:** Arthralgia, decreased bone mineral density, myalgia, pain

**RESP:** **Asthma aggravation**, bronchitis, **bronchospasm**, increased cough, upper respiratory tract infection, wheezing

**SKIN:** Pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, flu-like symptoms, viral infection

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is excreted in breast milk although other corticosteroids are.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Be aware that Asmanex brand of mometasone contains small amounts of lactose, which contains trace levels of milk proteins. Do not administer to patients with a milk protein allergy because anaphylactic reactions have occurred.

- Use mometasone cautiously if patient has ocular herpes simplex; tubercular infection; or untreated bacterial, fungal, or systemic viral infection.
- If patient takes an oral corticosteroid, expect to taper it slowly 1 week after changing to mometasone. If patient takes prednisone, expect to reduce it by no more than 2.5 mg daily at weekly intervals, beginning at least 1 week after mometasone therapy starts. Monitor patient for symptoms of systemically active corticosteroid withdrawal such as depression, joint and muscle pain, and lassitude, despite maintenance or even improvement of respiratory symptoms.

**WARNING** Assess patient switched from systemic corticosteroid to mometasone for adrenal insufficiency (fatigue, hypotension, lassitude, nausea, vomiting, weakness) during initial treatment and during infection, stress, surgery, trauma, or an electrolyte-depleting condition. Notify prescriber immediately if signs or symptoms arise because adrenal insufficiency may be life-threatening. Hypothalamic-pituitary-adrenal axis function may take several months to recover after systemic corticosteroids are discontinued. Abrupt withdrawal of mometasone also may precipitate adrenal insufficiency.

- Notify prescriber immediately if patient has bronchospasm after mometasone oral inhalation, and expect to give a fast-acting inhaled bronchodilator, discontinue mometasone, and use an alternate drug.
- Closely monitor a child's growth pattern; drug may stunt growth.
- Report oropharyngeal candidiasis, and expect patient to receive appropriate antifungal therapy while remaining on mometasone therapy. If candidiasis is severe, however, mometasone therapy may need to be temporarily halted.

## PATIENT TEACHING

- For nasal spray, instruct patient to shake container before each use. Instruct her to blow her nose, tilt her head slightly forward, and insert tube into a nostril, pointing toward inner corner of eye, away from nasal septum. Tell her to hold the other nostril closed and spray while inhaling gently. Then have her repeat the procedure in the other nostril.
- For oral inhalation using the Asmanex Twisthaler inhaler, give patient these instructions for using inhaler: Remove cap only after placing inhaler in an upright position. Twist cap in counterclockwise while holding colored base, making sure indented arrow (on white portion of the inhaler directly above the colored base) is pointing to the dose counter. Removing the cap loads inhaler with drug, and the dose counter on the base will count down by one. Tell her to take a full breath in and out, and then place mouthpiece in her mouth. Firmly close her lips around mouthpiece, taking care not to cover ventilation holes on the inhaler. Then take a fast, deep breath. Remind her she may not taste, smell, or feel anything with the inhalation. After taking the breath, she should remove inhaler from her mouth and hold her breath for about 10 seconds. She should not exhale into the inhaler. Then, she should wipe the mouthpiece dry, if needed, and replace the cap right away, turning it clockwise as she presses down. She should hear a click when the cap is fully closed. Tell her to write down the date inhaler is opened, and discard it 45 days from that date or when dose counter reads 00, whichever comes first.
- For oral inhalation using Asmanex HFA inhaler, instruct patient to remove cap from the mouthpiece of the actuator. If using the inhaler for the first time, tell patient to prime it by releasing 4 test sprays into the air, away from the face, shaking well before each spray. If inhaler has not been used for more than 5 days, inhaler requires priming again. Warn patient only to use the Asmanex HFA canister with the Asmanex HFA actuator. Instruct patient not to wash inhaler in water but to wipe the mouthpiece clean using a dry wipe after every seven days of use.
- Instruct patient to gargle or rinse after each use of oral inhaler to help prevent mouth and throat dryness, relieve throat irritation, and prevent oropharyngeal infection.

**WARNING** Caution patient not to use mometasone oral inhalation to relieve acute bronchospasm and to notify prescriber if rescue inhaler is required more often or doesn't seem to be as effective.

- Keep in mind that if patient switches from an oral corticosteroid to mometasone, she should be advised to carry or wear medical identification indicating the need for supplemental systemic corticosteroids during stress or severe asthma attack. Tell her to seek emergency care if either occurs.
- Instruct patient to contact prescriber if symptoms persist or worsen after 3 weeks.
- Caution patient to avoid exposure to chickenpox and measles and, if exposed, to contact prescriber immediately. Also alert patient of potential worsening of existing infections.
- Urge patient to seek emergency care if allergic reactions occur and to stop taking drug.
- Review adverse reactions with patient and family and to contact prescriber if bothersome or severe.

## montelukast sodium

### Singulair

## Class and Category

*Pharmacologic class:* Leukotriene receptor antagonist

*Therapeutic class:* Antiallergen, antiasthmatic

## Indications and Dosages

➤ *To prevent or treat asthma*

### ORAL GRANULES

**Children ages 1 to 5.** 4 mg daily in the evening.

*Maximum:* 4 mg daily.

## **CHEWABLE TABLETS**

**Children ages 6 to 14.** 5 mg daily in the evening.

*Maximum:* 5 mg daily.

**Children ages 2 to 5.** 4 mg daily in the evening.

*Maximum:* 4 mg daily.

## **TABLETS**

**Adults and adolescents age 15 and over.** 10 mg daily in the evening. *Maximum:* 10 mg daily.

➤ *To treat seasonal allergic rhinitis*

## **ORAL GRANULES**

**Children ages 2 to 5.** 4 mg daily.

## **CHEWABLE TABLETS**

**Children ages 6 to 14.** 5 mg daily.

**Children ages 2 to 5.** 4 mg daily.

## **TABLETS**

**Adults and adolescents age 15 and over.** 10 mg daily.

➤ *To treat perennial allergic rhinitis*

## **ORAL GRANULES**

**Children ages 6 months to 5 years.** 4 mg daily.

## **CHEWABLE TABLETS**

**Children ages 6 to 14.** 5 mg daily.

**Children ages 2 to 5.** 4 mg daily.

## **TABLETS**

**Adults and adolescents age 15 and over.** 10 mg daily.

➤ *To prevent exercise-induced broncho-constriction*

## **TABLETS**

**Adults and adolescents age 15 and over.** 10 mg at least 2 hr before exercise. *Maximum:* 10 mg in 24 hr.

## **CHEWABLE TABLETS**

**Children ages 6 to 14.** 5 mg at least 2 hr before exercise. *Maximum:* 5 mg in 24 hr.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	24 hr

## **Mechanism of Action**

Antagonizes receptors for cysteinyl leukotrienes, produced by arachidonic acid metabolism and released from eosinophils, mast cells, and other cells. When cysteinyl leukotrienes bind to receptors in bronchial airways, they increase endothelial membrane permeability, which leads to airway edema, smooth-muscle contraction, and altered activity of cells in asthma's inflammatory process. Also, antagonizes receptors for cysteinyl leukotrienes in nasal tissue that are responsible for producing rhinitis caused by allergens. Montelukast blocks these effects.

## **Contraindications**

Hypersensitivity to montelukast or its components

## **Interactions**

## DRUGS

*phenobarbital*: Decreased amount of circulating  
montelukast

## Adverse Reactions

**CNS:** Aggression, agitation, anxiousness, asthenia, attention disturbance, depression, disorientation, dizziness, dream abnormalities, drowsiness, fatigue, fever, hallucinations, headache, hostility, hypoesthesia, insomnia, irritability, memory impairment, obsessive-compulsive symptoms, paresthesia, restlessness, **seizures**, sleep walking, somnambulism, somnolence, stuttering, **suicidal ideation**, tic, tremor

**CV:** Palpitations, edema

**EENT:** Dental pain, epistaxis, laryngitis, nasal congestion, otitis media, pharyngitis, sinusitis

**GI:** Abdominal pain, **cholestatic hepatitis**, diarrhea, dyspepsia, elevated liver enzymes, **hepatic eosinophilic infiltration**, **hepatotoxicity**, indigestion, infectious gastroenteritis; diarrhea, nausea, **pancreatitis**, vomiting

**GU:** Enuresis (children), pyuria

**HEME:** **Increased bleeding tendency**, systemic eosinophilia, **thrombocytopenia**

**MS:** Arthralgia, muscle cramps, myalgia

**RESP:** Cough, upper respiratory tract infection, **pulmonary eosinophilia**

**SKIN:** **Erythema multiforme**, erythema nodosum, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema** (in all patients); flu-like syndrome, viral infection (in children)

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

**WARNING** Know that montelukast isn't for acute asthma attack or status asthmaticus.

- Keep in mind that montelukast shouldn't be abruptly substituted for inhaled or oral corticosteroids; expect to taper corticosteroid dosage gradually, as directed.
- Monitor patient for adverse reactions, such as eosinophilia, cardiac and pulmonary symptoms, and vasculitis, in patient undergoing corticosteroid withdrawal. Notify prescriber if such reactions occur.
- Watch patient closely for suicidal tendencies during montelukast therapy, especially when therapy starts or dosage changes.
- Monitor patient for adverse neuropsychiatric effects and notify prescriber if present. Drug may need to be discontinued.

## PATIENT TEACHING

- Advise patient to take montelukast daily as prescribed, even when he feels well. Urge him not to decrease dosage or stop taking other prescribed allergy or asthma drugs unless instructed by prescriber.

- Caution patient prescribed drug for asthma not to use drug for acute asthma attack or status asthmaticus; make sure he has appropriate short-acting rescue drug available.
- Tell parents administering oral granules to pour contents directly into the child's mouth or mix with ice cream or cold or room temperature applesauce, carrots, or rice—but not liquids or other foods—just before administration. Liquids may be given after drug has been administered. Once packet is opened, the full dose must be administered within 15 minutes. Drug must not be stored for future use if mixed with food.
- Instruct patient prescribed drug for asthma to notify prescriber if he needs a short-acting inhaled bronchodilator more often than usual, or more often than prescribed, to control symptoms.
- Teach patient prescribed drug for asthma to use a peak flowmeter to determine his personal best expiratory volume.
- Caution patient with aspirin sensitivity to avoid aspirin and NSAIDs during montelukast therapy. Montelukast may not effectively reduce bronchospasm in such a patient.
- Inform patient (or parents of child) with phenylketonuria that chewable tablet contains phenylalanine.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including depression, stuttering, or suicidal tendencies, during therapy, and urge them to notify prescriber if present.
- Instruct patient to report increased bleeding tendency or severe skin reaction that occurs without warning immediately to prescriber.

## morphine sulfate

**Arymo ER, Astramorph PF,  
Duramorph PF, Infumorph, Kadian,  
M-Eslon (CAN), MorphaBond ER,  
MS Contin, MSIR, Statex (CAN)**

# Class, Category, and Schedule

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

## Indications and Dosages

- *To relieve pain severe enough to require opioid treatment and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated*

### **TABLETS**

**Adults.** 15 to 30 mg every 4 hr, as needed.

### **ORAL SOLUTION**

**Adults.** 10 to 20 mg every 4 hr, as needed.

### **I.V. INFUSION**

**Adults.** *Initial:* 0.1 to 0.15 mg/kg/hr.

**Children.** 0.01 to 0.04 mg/kg/hr postoperatively, 0.04 to 0.07 mg/kg/hr for severe chronic cancer pain or sickle cell crisis.

### **I.V. INJECTION**

**Adults.** 0.1 to 0.2mg/kg injected slowly over 4 to 5 min every 4 hr, as needed.

### **I.M. OR SUBCUTANEOUS INJECTION**

**Adults.** 10 mg every 4 hr, as needed.

## **EPIDURAL INJECTION (MORPHINE SULFATE PRESERVATIVE FREE)**

**Adults.** *Initial:* 5 mg as a single dose. If pain isn't relieved after 1 hr, 1- to 2-mg doses given at appropriate intervals to relieve pain. *Maximum:* 10 mg/24 hr.

## **EPIDURAL INJECTION (INFUMORPH)**

**Adults with no tolerance to opioids.** *Initial:* 3.5 to 7.5 mg/day.

**Adults with some tolerance to opioids.** *Initial:* 4.5 to 10 mg/day.

## **INTRATHECAL INJECTION (MORPHINE SULFATE PRESERVATIVE FREE)**

**Adults.** 0.2 to 1 mg as a single dose.

## **INTRATHECAL INJECTION (INFUMORPH)**

**Adults with no tolerance to opioids.** *Initial:* 0.2 to 1 mg/day.

**Adults with some tolerance to opioids.** *Initial:* 1 to 10 mg/day.

## **SUPPOSITORIES**

**Adults.** 10 to 20 mg every 4 hr, as needed.

**Children.** Individualized dosage based on patient's age, size, and need.

- *To manage moderate to severe pain when a continuous, around-the-clock opioid analgesic is needed for an extended period of time*

## **E.R. CAPSULES (KADIAN)**

**Adults who are not opioid tolerant.** *Initial:* 30 mg every 24 hr, as needed.

**Adults converting from other oral morphine**

**formulations:** Total previous daily dose every 24 hr.

Alternatively, one-half total previous daily dose every 12 hr.

**Adults converting from parenteral morphine.** Highly individualized. *Usual:* Three times the previous daily parenteral morphine dosage.

**Adults converting from other nonmorphine opioids (oral or parenteral).** Highly individualized. *Usual:* Half of the estimated daily morphine requirements every 24 hr, and then increased as needed.

## **E.R. TABLETS (MORPHABOND, MS CONTIN)**

**Adults who are not opioid tolerant.** 15 mg every 8 hr (MS Contin) or 8 to 12 hr (Morphabond E.R.), as needed.

**Adults converting from other oral morphine**

**formulations.** One-half of patient's previous 24-hr requirements every 12 hr. Alternatively for MS Contin, one-third of patient's previous 24-hr requirements every 8 hr.

**Adults converting from parenteral morphine.** Highly individualized. *Usual:* Three times the previous daily parenteral morphine dosage.

**Adults converting from other parenteral or oral nonmorphine opioids.** Highly individualized. *Usual:* Half of the estimated daily morphine requirements, and then increased as needed.

## **E.R. TABLETS (ARYMO ER)**

**Adults who are not opioid tolerant.** 15 mg every 8 or 12 hr.

**Adults converting from other oral morphine**

**formulations.** One-half of patient's previous 24-hr

requirements every 12 hr. Alternatively, one-third of patient's previous 24-hr requirements every 8 hr.

**Adults converting from parenteral morphine.** Highly individualized. *Usual:* Three times the previous daily parenteral morphine dosage.

**Adults converting from other opioids.** 15 mg every 8 to 12 hr.

Route	Onset	Peak	Duration
P.O.	Unknown	1-2 hr	4-5 hr
P.O. (E.R.)	Unknown	Unknown	8-12 hr
I.V.	Unknown	20 min	4-5 hr
I.M.	10-30 min	30-60 min	4-5 hr
SubQ	10-30 min	50-90 min	4-5 hr
Epidural	15-60 min	Unknown	Up to 24 hr
Intrathecal	15-60 min	Unknown	Up to 24 hr
P.R.	20-60 min	Unknown	Unknown

## Mechanism of Action

Binds with and activates opioid receptors (mainly mu receptors) in brain and spinal cord to produce analgesia and euphoria.

## Contraindications

*For all forms:* Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment; gastrointestinal obstruction, including paralytic ileus; hypersensitivity to morphine sulfate or its components; significant respiratory depression; use of MAO inhibitors within past 14 days; *For neuraxial administration:* Concomitant anticoagulant therapy,

infection at the injection microinfusion site, presence of any other concomitant therapy or medical condition which would render epidural or intrathecal administration of morphine especially hazardous

## Interactions

### DRUGS

*5-HT<sub>3</sub> receptor antagonists; cyclobenzaprine; linezolid; methylene blue; selected psychiatric drugs such as amoxapine, buspirone, lithium, mirtazapine, nefazodone, trazodone, vilazodone; selective serotonin reuptake inhibitors; serotonin-norepinephrine reuptake inhibitors; St. John's wort; tricyclic antidepressants; tramadol; triptans; tryptophan:* Increased risk of serotonin syndrome  
*anticholinergics:* Possibly severe constipation leading to ileus, urine retention  
*antipsychotics, anxiolytics, benzodiazepines, cimetidine, CNS depressants, general anesthetics, muscle relaxants other opioids, P-glycoprotein inhibitors, sedating antihistamines, tranquilizers, tricyclic antidepressants:* Increased additive effects increasing risk of coma, hypotension, profound sedation, respiratory depression, death  
*diuretics:* Decreased diuretic efficacy  
*MAO inhibitors:* Increased risk of opioid toxicity (coma, respiratory depression) or serotonin syndrome  
*mixed agonist-antagonist and partial agonist analgesics such as butorphanol, buprenorphine, nalbuphine, pentazocine:* Possibly withdrawal symptoms or reduced analgesic effect  
*oral P2Y<sub>12</sub> inhibitors:* Decreased absorption and peak concentration of oral P2Y<sub>12</sub> inhibitors and delay onset of

antiplatelet effect when given with intravenous morphine sulfate

## ACTIVITIES

*alcohol use:* Increased morphine plasma levels and potentially fatal overdose of morphine from increased CNS and respiratory depression and hypotension

## Adverse Reactions

**CNS:** Agitation, amnesia, anxiety, ataxia, chills, **coma**, confusion, decreased concentration, delirium, delusions, depression, dizziness, dream abnormalities, drowsiness, edema, euphoria, fever, gait disturbance, hallucinations, headache, **increased intracranial pressure**, insomnia, lethargy, light-headedness, malaise, mood alterations, psychosis, restlessness, rigidity, sedation, **seizures**, syncope, thinking disturbances, tremor, uncoordinated muscle movements, unresponsiveness, vertigo, weakness

**CV:** **Bradycardia**, **cardiac arrest**, edema, hypertension, **hypotension**, orthostatic hypotension, palpitations, **shock**, tachycardia, vasodilation

**EENT:** Amblyopia, blurred vision, diplopia, dry mouth, eye pain, hiccup, **laryngeal edema or laryngospasm** (allergic), miosis, nystagmus, rhinitis, taste or voice alteration

**ENDO:** **Adrenal insufficiency** (rare), hypogonadism

**GI:** Abdominal cramps or pain, anorexia, biliary tract spasm, constipation, diarrhea, dysphagia, elevated liver enzymes, gastroenteritis, gastroesophageal reflux, hiccups, ileus (in patients with inflammatory bowel disease), **toxic megacolon** (in patients with inflammatory bowel disease), indigestion, **intestinal obstruction**, nausea, vomiting

**GU:** Decreased ejaculate potency, decreased libido, difficult ejaculation, dysuria, impotence, infertility, menstrual irregularities, oliguria, prolonged labor, urinary hesitancy, urine retention

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, decreased bone mineral density, skeletal muscle rigidity

**RESP:** **Apnea**, **asthma exacerbation**, **atelectasis**, **bronchospasm**, depressed cough reflex, **hypoventilation**, **pulmonary edema**, **respiratory arrest and depression**, wheezing

**SKIN:** Diaphoresis, dryness, flushing, pallor, pruritus, rash, urticaria

**Other:** **Allergic reaction**; **anaphylaxis**; **angioedema**; injection-site edema, pain, rash, or redness; physical and psychological dependence; weight loss; withdrawal symptoms

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the neonate. Monitor

neonate closely for signs of excess sedation and respiratory depression.

- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## REPRODUCTION

- Chronic use of opioids may reduce fertility.

## Nursing Considerations

- Be aware that morphine can lead to abuse, addiction, and misuse. To ensure that benefits of morphine therapy outweigh risks, a Risk Evaluation and Mitigation Strategy (REMS) is required.

**WARNING** Know that chronic maternal use of morphine during pregnancy can result in NOWS, which may be life-threatening if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to opioid drugs like morphine for a prolonged period while in utero.

**WARNING** Use extreme caution when administering morphine to patients with conditions accompanied by hypercapnia, hypoxia, or decreased respiratory reserve such as asthma, chronic obstructive pulmonary disease (COPD), or cor pulmonale. This is because, even with usual therapeutic doses, morphine may decrease respiratory drive while simultaneously increasing airway resistance to the point of apnea. Monitor

patient's respiratory status closely, especially during the initiation of therapy or following a dose increase.

**WARNING** Use morphine with extreme caution in patients who may be at risk for carbon dioxide retention (e.g., those with brain tumors or increased intracranial pressure). Monitor for signs of sedation and respiratory depression, especially when initiating therapy. Morphine may reduce respiratory drive, and the resultant carbon dioxide retention can further increase intracranial pressure. Also know that opioids like morphine may obscure signs and symptoms in a patient with a head injury.

**WARNING** Know that morphine should only be used concomitantly with benzodiazepine and other CNS depressant therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of morphine to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Use cautiously in patients about to undergo surgery of the biliary tract and patients with acute pancreatitis secondary to biliary tract disease because morphine may cause spasm of the sphincter of Oddi.
- Be aware that MorphaBond ER formulation has an added abuse deterrent property that makes it difficult to break, crush, or cut the tablet. It also resists extraction and forms a viscous liquid when physically compromised and placed in a liquid. This abuse deterrent helps prevent abuse when attempts are made to administer it intranasally or by injection.
- Store morphine at room temperature.
- Ensure that before giving morphine, opioid antagonist and equipment for oxygen delivery and respiration are available.
- Assess patient's drug use, including all prescription and OTC drugs before therapy begins.

- Expect prescriber to usually start patient who has never received opioids on immediate-release form and then switch to E.R. form if therapy must last longer than a few days.
- Keep in mind that when morphine is given by epidural route, dosage must be individualized according to patient's age, body mass, physical status, previous experience with opioids, risk factors for respiratory depression, and drugs to be coadministered before or during surgery.
- Give oral form with food or milk to minimize adverse GI reactions, if needed. Solution can be mixed with fruit juice to improve taste.
- Open E.R. capsules and sprinkle contents on applesauce (at room temperature or cooler) just before giving to patient, if needed. Make sure patient doesn't chew or crush capsules or dissolve capsule's pellets in his mouth.
- Be aware that E.R. forms of morphine aren't interchangeable.
- Discard injection solution that is discolored or darker than pale yellow or that contains precipitates that don't dissolve with shaking.

**WARNING** Don't use highly concentrated solutions (such as 10 to 25 mg/ml) for single-dose I.V., I.M., or subcutaneous administration. These solutions are intended for use in continuous, controlled microinfusion devices.

- For direct I.V. injection, dilute appropriate dose with 4 to 5 ml of sterile water for injection. Inject 2.5 to 15 mg directly into tubing of free-flowing I.V. solution over 4 to 5 minutes. Rapid I.V. injection may increase adverse reactions.
- For continuous I.V. infusion, dilute drug in D<sub>5</sub>W and administer with infusion-control device. Adjust dose and rate based on patient response, as prescribed.
- Avoid I.M. route for long-term therapy because of injection-site irritation.
- During subcutaneous injection, take care to avoid injecting drug intradermally.
- For intrathecal injection, expect prescriber to give no more than 2 ml of 0.5-mg/ml solution or 1 ml of 1-mg/ml solution. Expect intrathecal dosage to be about one-tenth of epidural dosage.

- Keep in mind if rectal suppository is too soft to insert, refrigerate for 30 minutes or run wrapped suppository under cold tap water.

**WARNING** Monitor circulatory and respiratory status carefully and frequently during morphine therapy, especially when drug therapy is initiated and when patient is being converted to morphine because respiratory depression and severe hypotension can develop. Be especially vigilant with cachectic, debilitated, and elderly patients who are at higher risk. Know that life-threatening depression can occur even when morphine is taken as prescribed and is not misused or abused.

- Monitor patient with seizure disorder for increased seizure activity because morphine may worsen the disorder.
- Monitor patient for excessive or persistent sedation; dosage may need to be adjusted.
- Know that if patient is receiving a continuous morphine infusion, watch for and notify prescriber about new neurologic signs or symptoms. Inflammatory masses (such as granulomas) have caused serious neurologic reactions, including paralysis.
- Expect morphine to cause physical and psychological dependence; watch for drug tolerance and withdrawal, such as body aches, diaphoresis, diarrhea, fever, piloerection, rhinorrhea, sneezing, and yawning.
- Keep in mind if tolerance to morphine develops, expect prescriber to increase dosage.
- Know that morphine may have a prolonged duration and cumulative effect in patients with impaired hepatic or renal function. It also may prolong labor.

**WARNING** Know that many drugs may interact with opioids like morphine to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with

coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, and weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If confirmed, expect to administer corticosteroids and wean patient off morphine, if possible.
- Keep in mind when discontinuing morphine in patients receiving more than 30 mg daily, expect prescriber to reduce daily dose by about one-half for 2 days and then by 25% every 2 days thereafter until total dose reaches initial amount recommended for patients who haven't received opioids (15 to 30 mg daily). This regimen minimizes the risk of withdrawal symptoms.

## **PATIENT TEACHING**

- Instruct patient to take morphine exactly as prescribed and not to change dosage without consulting prescriber. Tell patient this is because excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death.
- Explain that patient may take tablets or capsules with food or milk to relieve GI distress and may mix oral solution with juice to improve taste.
- Urge patient not to break, chew, or crush E.R. capsules and tablets to avoid rapid release and, possibly, toxicity.
- Tell patient who has difficulty swallowing, suggest that he can open E.R. capsules and sprinkle contents on food or liquids. Urge him to take drug immediately and not let capsule contents dissolve in his mouth.
- Instruct patient to moisten rectal suppository before inserting it.
- Urge patient to avoid alcohol and other CNS depressants, including benzodiazepines, during therapy without prescriber knowledge, as severe respiratory depression can occur and may lead to death.
- Advise patient to avoid potentially hazardous activities during morphine therapy.
- Tell patient to change positions slowly to minimize the orthostatic hypotension.

- Instruct patient to notify prescriber about worsening or breakthrough pain.
- Explain that morphine may be habit-forming. Urge him to notify prescriber if he experiences anxiety, decreased appetite, excessive tearing, irritability, muscle aches or twitching, rapid heart rate, or yawning.
- Advise female patient to notify prescriber if she becomes pregnant. Regular morphine use during pregnancy may cause physical dependence in fetus and withdrawal in neonate.
- Inform breastfeeding mothers that breastfeeding is not recommended during morphine therapy.
- Tell patient to alert all prescribers of morphine use. This is important because a potentially fatal effect can occur when an opioid like morphine is combined with a benzodiazepine.
- Warn patient not to discontinue morphine use abruptly if more than a few weeks of use has occurred, as withdrawal symptoms may develop.
- Caution patient to keep drug out of reach of children because accidental consumption by a child may be fatal.
- Inform patient that long-term use of opioids like morphine may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms.
- Instruct patient that when morphine is no longer needed, patient should dispose of drug promptly. Expired, unused, or unwanted drug can be disposed of by flushing the drug down the toilet if a drug-take back option is not available.

## moxifloxacin hydrochloride

**Avelox, Avelox IV**

### **Class and Category**

*Pharmacologic class:* Fluoroquinolone

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute sinusitis caused by Haemophilus influenzae, Moraxella catarrhalis, or Streptococcus pneumoniae; to treat mild to moderate community-acquired pneumonia caused by Chlamydia pneumoniae, H. influenzae, Klebsiella pneumoniae, M. catarrhalis, Mycoplasma pneumoniae, Staphylococcus aureus, or S. pneumoniae (including penicillin- or multi-drug-resistant strains)*

### **TABLETS, I.V. INFUSION**

**Adults.** 400 mg every 24 hr for 10 days for acute sinusitis and 7 to 14 days for community-acquired pneumonia. I.V. infusion given over 1 hr.

- *To treat acute exacerbation of chronic bronchitis caused by H. influenzae, H. parainfluenzae, Klebsiella pneumoniae, M. catarrhalis, S. pneumoniae, or Staphylococcus aureus*

### **TABLETS, I.V. INFUSION**

**Adults.** 400 mg every 24 hr for 5 days. I.V. infusion given over 1 hr.

- *To treat uncomplicated skin and soft-tissue infections caused by S. aureus or Streptococcus pyogenes*

### **TABLETS, I.V. INFUSION**

**Adults.** 400 mg every 24 hr for 7 days. I.V. infusion given over 1 hr.

- *To treat complicated skin and skin structure infections caused by Enterobacter cloacae, E. coli, K.*

pneumoniae, **or** *S. aureus*

## **TABLETS, I.V. INFUSION**

**Adults.** 400 mg every 24 hr for 7 to 21 days. I.V. infusion given over 1 hr.

- *To treat complicated intra-abdominal infections, including polymicrobial infections such as abscesses caused by Bacteroides fragilis, B. thetaiotaomicron, Clostridium perfringens, Enterococcus faecalis, E. coli, Peptostreptococcus species, Proteus mirabilis, Streptococcus anginosus, or S. constellatus*

## **TABLETS, I.V. INFUSION**

**Adults.** 400 mg every 24 hr for 5 to 14 days with initial dosage given as I.V. infusion over 1 hr.

- *To prevent or treat plague, including pneumonic and septicemic plague, caused by Yersinia pestis*

## **I.V. INFUSION, TABLETS**

**Adults.** 400 mg every 24 hr for 10 to 14 days after exposure confirmed or suspected. I.V. infusion given over 1 hr.

## **Mechanism of Action**

Inhibits synthesis of bacterial enzyme DNA gyrase by counteracting excessive supercoiling of DNA during replication or transcription. Inhibiting DNA gyrase causes rapid- and slow-growing bacterial cells to die.

## **Incompatibilities**

Don't infuse I.V. moxifloxacin simultaneously through the same I.V. line with other I.V. additives, drugs, or substances.

## Contraindications

Hypersensitivity to moxifloxacin, other fluoroquinolones, or their components; myasthenia gravis

## Interactions

### DRUGS

*aluminum- or magnesium-containing antacids; drug formulations with divalent or trivalent cations, such as didanosine chewable buffered tablets or powder for oral solution; metal cations, such as iron; multivitamins containing iron or zinc; sucralfate:* Possibly substantial interference with moxifloxacin absorption, causing low blood moxifloxacin level

*antidiabetic agents:* Increased risk of either hyperglycemia or hypoglycemia

*class IA antiarrhythmics, such as quinidine; class III antiarrhythmics, such as sotalol; other drugs known to prolong QTc interval, such as antipsychotics, cisapride, disopyramide erythromycin, pentamidine and tricyclic antidepressants:* Possibly prolonged QTc interval

*corticosteroids:* Increased risk of Achilles and other tendon ruptures

*NSAIDs:* Increased risk of CNS stimulation and seizures

*warfarin:* Possibly increased anticoagulation

## Adverse Reactions

**CNS:** Abnormal gait, agitation, altered coordination, anxiety, confusion, delirium, depression, disorientation, disturbance in attention, dizziness, fever, hallucinations, headache, **increased intracranial pressure (including pseudotumor cerebri)**, insomnia, memory impairment, paranoia, peripheral neuropathy, nervousness, psychosis, psychotic reaction, **seizures, suicidal ideation**, syncope, **toxic psychosis**, tremors

**CV:** **Aortic dissection**, hypertension, **hypotension** palpitations, peripheral edema, **prolonged QT interval, rupture of aortic aneurysm**, tachycardia, vasculitis, vasodilation, **ventricular tachyarrhythmias**

**EENT:** Altered taste, deafness or other hearing impairments, **laryngeal edema**, vision loss

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, abnormal liver enzymes, **acute hepatic necrosis, cholestatic hepatitis**, diarrhea, dyspepsia, **hepatic failure, hepatitis**, jaundice, nausea, **pseudomembranous colitis**, vomiting

**GU:** **Acute renal insufficiency or failure**, interstitial nephritis

**HEME:** **Agranulocytosis, aplastic anemia**, eosinophilia, **hemolytic anemia, leukopenia, pancytopenia, prolonged prothrombin time, thrombocytopenia**

**MS:** Arthralgia; muscle weakness; myalgia; tendon inflammation, pain, or rupture

**RESP:** **Allergic pneumonitis**

**SKIN:** Photosensitivity, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Anaphylaxis, anaphylactic shock, angioedema**, serum sickness, worsening of myasthenia gravis

## **Childbearing Considerations**

## PREGNANCY

- It is not known if drug causes fetal harm but animal studies suggest fetal harm may occur.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug maybe present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that if patient has hypokalemia, expect to correct it before beginning moxifloxacin therapy to prevent arrhythmias.
- Determine if patient has a history of CNS disorder, such as cerebral arteriosclerosis or epilepsy, because drug may lower seizure threshold. Notify prescriber before starting drug, and take seizure precautions.
- Be aware that there is an increased risk of aortic aneurysm and dissection within two months following use of moxifloxacin as a fluoroquinolone, especially in elderly patients. Moxifloxacin should be reserved for patients with a known aortic aneurysm or patients who are at greater risk for aortic aneurysms only when there are no alternative antibacterial therapies available.
- Use cautiously in patients with liver dysfunction, including cirrhosis, because drug may adversely affect liver function.
- Obtain a fluid or tissue specimen for culture and sensitivity, as ordered. Expect to begin therapy before results are available.

**WARNING** Keep in mind before starting moxifloxacin therapy, determine if patient takes a class IA antiarrhythmic, such as quinidine; a class III antiarrhythmic, such as sotalol; or other drugs that prolong the QTc interval, such as antipsychotics, cisapride, erythromycin, or tricyclic antidepressants. These drugs should be

avoided in patients taking moxifloxacin because they may prolong the QTc interval and lead to life-threatening ventricular tachycardia or torsades de pointes. Monitor patient closely throughout therapy, especially if he has significant acute myocardial ischemia or bradycardia because these conditions increase risk of prolonging the QTc interval.

- Infuse drug over 60 minutes with ready-to-use flexible bags with 400 mg of moxifloxacin in 250 ml of 0.8% saline. Don't dilute further.
- Know that if giving through Y-type tubing or piggyback, stop other solutions during moxifloxacin infusion, and flush the line before and after infusion with a compatible solution, such as 1M sodium chloride, 5% dextrose, sterile water for injection, 10% dextrose, lactated Ringer's or normal saline solution. Also flush line before and after giving other drugs in same I.V. line.
- Don't refrigerate I.V. moxifloxacin ready-to-use bags because precipitation will occur. Discard any unused portion; premixed bags are for single-use only.
- Expect to obtain a 12-lead ECG to assess patient for prolonged QTc interval. Ask patient if he or a blood relative has a history of prolonged QTc interval. Monitor elderly patients closely; they may have increased risk of prolonged QT interval.
- Monitor patient for central nervous system (including psychiatric) adverse reactions such as confusion, depression, dizziness, hallucinations, peripheral neuropathy, psychosis, suicidal ideation, and tremors. If any occurs, notify prescriber and expect moxifloxacin to be discontinued.
- Monitor patient for diarrhea. If profuse, watery diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold moxifloxacin and treat with fluids, an antibiotic effective against *C. difficile*, *electrolytes, fluids, and protein, as ordered*.
- Monitor serum potassium level, as ordered, during therapy to assess for hypokalemia.
- Keep emergency resuscitation equipment readily available, and observe for evidence of hypersensitivity, such as angioedema, dyspnea, and urticaria. If you suspect anaphylaxis, prepare to give epinephrine, corticosteroids, diphenhydramine, and epinephrine, as prescribed.

- Monitor patients who are prone to tendinitis, such as athletes, the elderly, and those taking corticosteroids, for complaints of tendon inflammation, pain, or rupture. If present, notify prescriber and expect to discontinue moxifloxacin, place patient on bedrest with no exercise of affected limb, and obtain diagnostic tests to confirm rupture.
- Monitor patient's blood glucose, especially in diabetic patients receiving concomitant treatment with insulin or an oral hypoglycemic agent, for changes in blood glucose levels that could become decreased or increased. If dysglycemia occurs, treat according to standard of care and expect that drug may need to be discontinued.
- Know that fluoroquinolones like moxifloxacin have caused disabling and potentially irreversible serious adverse reactions from different body systems that can occur together in the same patient. These reactions can occur within hours to weeks after starting the drug and usually cause central nervous system effects, peripheral neuropathy, tendinitis and tendon rupture. All ages of patients and patients without any preexisting risk factors have experienced these reactions. Notify prescriber and expect to discontinue moxifloxacin immediately at the first signs or symptoms of any serious adverse reactions.

## **PATIENT TEACHING**

- Urge patient to notify prescriber at once about fainting or palpitations because they may indicate a serious arrhythmia. Also, tell patient to seek emergency help immediately if patient develops sudden back, chest, or stomach pain.
- Teach patient to take drug at least 4 hours before and 8 hours after aluminum- or magnesium-containing antacids, didanosine chewable buffered tablets or oral solution prepared from powder, multivitamins containing iron or zinc, or sucralfate.
- Urge patient to drink plenty of fluids while taking moxifloxacin.
- Caution patient to stop drug and notify prescriber if he has a rash, trouble breathing, or other signs of an allergic reaction. Also advise patient to stop taking moxifloxacin immediately and notify prescriber if any persistent, serious, or worsening adverse effects occur.
- Urge patient to stop any exercise and contact prescriber immediately if he develops tendon inflammation, pain, or rupture.
- Tell patient to notify prescriber if motor or sensory changes occur.
- Caution patient to avoid hazardous activities until adverse CNS effects are known.

- Urge patient to tell prescriber if diarrhea develops, even more than 2 months after moxifloxacin therapy ends.
- Caution patient to complete the prescribed course of therapy even if he feels better before it's completed.
- Tell patient to avoid excessive exposure to sunlight or artificial ultraviolet light because severe sunburn may result. Instruct patient to notify prescriber if sunburn develops because moxifloxacin may have to be discontinued.
- Warn patient, especially diabetics, that moxifloxacin may alter blood glucose levels. Review signs and symptoms of hyperglycemia and hypoglycemia. Tell patient to report symptomatic changes in blood glucose levels to prescriber and review how to treat hypoglycemia.

**mycophenolate mofetil**

**CellCept**

**mycophenolate mofetil  
hydrochloride**

**CellCept, CellCept Intravenous**

**mycophenolic acid**

**Myfortic**

## **Class and Category**

*Pharmacologic class:* Mycophenolic acid

*Therapeutic class:* Immunosuppressant

# Indications and Dosages

- *To prevent organ rejection in patients receiving allogenic kidney transplants*

## **CAPSULES, ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults.** 1 g (over at least 2 hr for I.V. infusion) twice daily

### **E.R. TABLETS**

**Adults.** 720 mg twice daily 1 hr before or 2 hr after food intake.

**Children age 5 and older who are at least 6 months post kidney transplant.** 400 mg/m<sup>2</sup> twice daily.

*Alternatively,* 540 mg twice daily if body surface area is between 1.19 to 1.58 m<sup>2</sup> or 720 mg twice daily if body surface area is greater than 1.58 m<sup>2</sup>.

### **ORAL SUSPENSION**

**Children age 3 months to 18 years.** 600 mg/m<sup>2</sup> twice daily. *Maximum:* 2 g (10 ml) daily.

### **CAPSULES**

**Children with body surface area of 1.25 m<sup>2</sup> to less than 1.5 m<sup>2</sup>.** 750 mg twice daily.

### **CAPSULES, TABLETS**

**Children with body surface area of 1.5 m<sup>2</sup> or greater.** 1 g twice daily.

- *To prevent organ rejection in patients receiving allogenic heart transplants*

## **CAPSULES, ORAL SUSPENSION, TABLETS, I.V. INFUSION**

**Adults.** 1.5 g (over at least 2 hr for I.V. infusion) twice daily.

- *To prevent organ rejection in patients receiving allogeneic liver transplants*

## **I.V. INFUSION**

**Adults.** 1 g infused over at least 2 hr twice daily.

## **CAPSULES, ORAL SUSPENSION, TABLETS**

**Adults.** 1.5 g twice daily.

## **Mechanism of Action**

Hydrolyzes to form mycophenolic acid (MPA), which inhibits guanosine nucleotide synthesis and proliferation of T and B lymphocytes. MPA also suppresses antibody formation by B lymphocytes and prevents glycosylation of lymphocyte and monocyte glycoproteins involved in adhesion to endothelial cells. MPA also may inhibit leukocytes from sites of inflammation and graft rejection, which may explain how mycophenolate mofetil prolongs allogeneic transplant survival.

## **Incompatibilities**

Don't mix or give mycophenolate mofetil hydrochloride in same infusion catheter with other I.V. admixtures or drugs.

## **Contraindications**

Hypersensitivity to mycophenolate mofetil, mycophenolic acid, mycophenolate sodium, or any of their components; hypersensitivity to polysorbate 80 (I.V. form)

## Interactions

### DRUGS

*acyclovir, ganciclovir, probenecid, valacyclovir, valganciclovir*: Increased plasma concentrations and/or adverse reactions of these drugs  
*aminoglycosides, bile acid sequestrants, cephalosporins, fluoroquinolones, penicillins, rifampin, sulfamethoxazole/trimethoprim*: Decreased effectiveness of mycophenolate mofetil  
*antacids with aluminum and magnesium hydroxides, sevelamer*: Decreased absorption of oral mycophenolate mofetil  
*isavuconazole*: Increased risk of adverse reactions caused by mycophenolate mofetil  
*live vaccines*: Decreased effectiveness of live vaccines  
*oral contraceptives (combination)*: Possibly decreased effectiveness of oral contraceptives  
*proton pump inhibitors such as lansoprazole, pantoprazole*: Possibly decreased effectiveness of mycophenolate mofetil  
*telmisartan*: Decreased mycophenolate mofetil system exposure reducing effectiveness

## Adverse Reactions

**CNS**: Agitation, anxiety, chills, confusion, delirium, depression, dizziness, emotional lability, fever, hallucinations, headache, hypertonia, hypesthesia, insomnia, malaise, meningitis, nervousness, neuropathy, paresthesia, **progressive multifocal**

**leukoencephalopathy**, psychosis, **seizures**, somnolence, syncope, thinking abnormality, tremor, vertigo

**CV:** Angina pectoris, **arrhythmias**, **arterial thrombosis**, **atrial fibrillation or flutter**, **bradycardia**, **cardiac arrest**, CV disorder, **congestive heart failure**, **extrasystoles**, generalized edema, **hemorrhage**, hypercholesterolemia, hyperlipemia, hypertension, **hypotension**, increased lactic dehydrogenase, increased SGOT and SGPT, increased venous pressure, **infectious endocarditis**, orthostatic hypotension, palpitations, **pericardial effusion**, peripheral edema, peripheral vascular disorder, **supraventricular tachycardia**, **thrombosis**, vasodilation, vasospasm, **ventricular extrasystole**, **ventricular tachycardia**

**EENT:** Amblyopia, cataract, conjunctivitis, deafness, dry mouth, ear disorder or pain, epistaxis, eye hemorrhage, gingivitis, gum hyperplasia, lacrimation disorder, mouth ulceration, oral candidiasis, pharyngitis, rhinitis, sinusitis, stomatitis, tinnitus, vision abnormality, voice alteration

**ENDO:** Cushing's syndrome, diabetes mellitus, hypercalcemia, **hypoglycemia**, hypothyroidism, parathyroid disorder

**GI:** Abdomen enlargement or pain, anorexia, ascites, cholangitis, cholestatic jaundice, colitis, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes, esophagitis, flatulence, gastritis, gastroenteritis, **GI hemorrhage or perforation**, GI infection, GI candidiasis, **hepatitis**, hernia, ileus, intestinal villous atrophy, jaundice, **liver damage**, **melen**a, nausea, **pancreatitis**, **peritonitis**, rectal disorder, stomach ulcer, **ulceration of GI tract**, vomiting

**GU:** Albuminuria; bilirubinemia; BK virus-related nephropathy; dysuria; hematuria; hydronephrosis;

impotence; increased BUN or creatinine levels; **kidney tubular necrosis**; nocturia; oliguria; pain; polyomavirus-associated nephropathy; prostatic disorder; pyelonephritis; **renal failure**; scrotal edema, urinary tract disorder or infection; urine abnormality, frequency, incontinence, or retention

**HEME:** Anemia, **bone marrow failure**, **coagulation disorder**, hypochromic anemia, hypogammaglobulinemia, **increased prothrombin time or thromboplastin time**, leukocytosis, **leukopenia**, **neutropenia**, **pancytopenia**, polythemia, pure red cell aplasia, **thrombocytopenia**

**MS:** Arthralgia; back, neck or pelvic pain; joint disorder; leg cramps; myalgia; myasthenia; osteoporosis

**RESP:** **Apnea**; **asthma**; **atelectasis**; bronchiectasis; bronchitis; candidiasis; cough; dyspnea; **hemoptysis**; interstitial lung disease; hyperventilation; **hypoxia**; **neoplasm**; pleural effusion; pneumonia; **pneumothorax**; **pulmonary edema**, **fibrosis**, or **hypertension**; **respiratory acidosis**; sputum increase

**SKIN:** Abscess; acne; alopecia, cellulite; ecchymosis; fungal dermatitis; hirsutism; pallor; petechia; pruritus; rash; benign neoplasm, **carcinoma**, hypertrophy, or ulcer; sweating; vesiculobullous rash

**Other:** Abnormal healing; **acidosis**; activation of latent infections (such as tuberculosis) or **reactivation of hepatitis B or hepatitis C**; **alkalosis**; **angioedema**; bacterial, fungal, protozoal, and viral infections, including opportunistic infections; congenital defects; cyst; dehydration; flu-like syndrome; gout; hiccup; **hyperkalemia**; hypersensitivity reactions; hyperuricemia; hypervolemia; hypochloremia; **hypocalcemia**; **hypokalemia**; **hypomagnesemia**; **hyponatremia**; hypophosphatemia; hypoproteinemia; increased alkaline phosphatase; increased gamma glutamyl transpeptidase; loss of pregnancy during first trimester; lymphocele,

lymphoma; malignancies; sepsis; thirst; weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-617-8191 or [www.mycophenolateREMS.com](http://www.mycophenolateREMS.com).
- Drug causes fetal harm such as an increased risk of first trimester pregnancy loss and an increased risk of multiple congenital malformations in multiple organ systems.
- A negative pregnancy test should be performed and a second one done 8 to 10 days later before drug therapy is begun.
- Drug is not recommended for use during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Know that female patients of childbearing age must receive contraceptive counseling and use an effective contraceptive throughout drug therapy and for 6 weeks following drug discontinuation unless abstinence is practiced.
- Know that male patients and their partner must also receive contraceptive counseling and use an effective contraceptive throughout drug therapy for male patient and for 90 days following drug discontinuation unless abstinence is practiced.
- Inform female patient that drug may make combination oral hormonal contraceptives ineffective.
- Female patient or female partner should be made aware that follow up pregnancy testing will be done during drug use.

- Instruct male patients not to donate sperm during drug therapy and for at least 90 days following drug discontinuation.

## Nursing Considerations

- Keep in mind, before starting mycophenolate therapy in a woman of childbearing potential, to make sure she has a negative pregnancy test within 1 week of starting therapy, using a test with a sensitivity of at least 25 mIU/ml. Therapy shouldn't start until results are confirmed.
- Know that mycophenolate mofetil therapy should be avoided in patients with hypoxanthine-guanine phosphoribosyl-transferase deficiency, because drug may exacerbation of disease symptoms.
- Expect to give I.V. form within 24 hours of transplantation and for no longer than 14 days. Expect to switch patient to oral form as soon as possible, as ordered.
- Keep in mind when preparing I.V. form or oral suspension, avoid inhalation, or direct contact with skin or mucous membranes. If contact occurs, wash area thoroughly with soap and water and rinse eyes with water.
- Prepare oral suspension tapping closed bottle several times to loosen powder and then measure 94 ml of water in a graduated cylinder. Add half of the water to the bottle and shake for about 1 minute. Then add remainder of water and shake again for 1 minute. Remove child-resistant cap and push bottle adapter into neck of bottle. Close bottle tightly with child-resistant cap. Be aware that the suspension bottle may become cold immediately after reconstitution.
- Know that oral suspension can be administered by 8F or larger nasogastric tube.
- Be aware that when giving oral suspension, don't mix with any other drugs. Ask patient about history of phenylketonuria before initial administration because oral suspension contains aspartame.
- Don't open or crush capsules. If necessary, use the oral suspension.
- Handle I.V. form similarly to a chemotherapeutic drug because mycophenolate mofetil is embryotoxic and genotoxic and may have mutagenic properties.
- Know that I.V. form must be reconstituted and diluted to 6 mg/ml using 5% dextrose injection USP. Inject 14 ml 5% dextrose injection USP into each vial (2 vials will be needed for each 1-g dose; 3 vials for each 1.5-g

dose), then shake gently. Further dilute a 1-g dose by adding 2 reconstituted vials to 140 ml of 5% dextrose injection USP; dilute a 1.5-g dose by adding 3 reconstituted vials to 210 ml of 5% dextrose injection USP.

- Be aware that I.V. form should be administered within 4 hours of once reconstituted, as an infusion and over no less than 2 hours. Never administer by rapid or bolus I.V. injection because of increased risk of local reactions such as phlebitis and thrombosis.
- Know that extended release form of mycophenolate mofetil should not be given to children who have a body surface area of less than 1.19 m<sup>2</sup>. Also be aware that extended release form is not interchangeable with other forms of the drug.
- Know that corticosteroids and cyclosporine should be used with mycophenolate mofetil therapy.
- Obtain CBC weekly during first month of therapy, twice monthly for the second and third months of therapy, and then monthly through the first year, as ordered. Notify prescriber of any abnormalities. If significant, anticipate dosage reduction if absolutely necessary because reduced immunosuppression increases the risk of organ rejection. Also provide supportive care.
- Monitor patient's serum creatinine levels, as ordered, to detect changes in kidney function because drug may cause polyomavirus-associated nephropathy. Notify prescriber if changes occur and expect dosage to be reduced, if needed.
- Monitor patient closely for adverse reactions because drug has many adverse effects, some of which can be serious or severe, such as the development of lymphoma and other malignancies, especially of the skin. Also know that patient may be at increased risk for bacterial, fungal, protozoal, and viral infections, including opportunistic infections and viral reactivation of hepatitis B and C, which may lead to hospitalization and possibly fatal outcome.
- Expect to stop drug or reduce the dose and provide supportive care, as ordered, if neutropenia develops.

**WARNING** Know that mycophenolate mofetil therapy has been associated with progressive multifocal leukoencephalopathy that can be life-threatening. Monitor patient for apathy, ataxia, cognitive deficiencies, and confusion. Report suspicions of disorder immediately to prescriber.

## PATIENT TEACHING

- Advise women of childbearing age that two forms of contraceptives should be used simultaneously before beginning mycophenolate mofetil therapy and for 6 weeks following discontinuation of therapy because of potential for fetal harm. Tell male patients that they and their female partner should use effective contraception during therapy and for 90 days following discontinuation of therapy. Inform women who use combination oral contraceptives that drug may decrease effectiveness of oral contraceptives. Urge patient to notify prescriber immediately if pregnancy occurs because drug increases risk of first-trimester pregnancy loss and congenital malformations.
- Tell patient about increased risk of lymphomas or other malignancies, especially of the skin, before therapy starts. Tell patient to report any unusual signs or symptoms to prescriber.
- Tell patient to take oral form of drug on an empty stomach.
- Inform patient prescribed oral suspension that it contains aspartame, which is a source of phenylalanine.
- Instruct patient not to crush tablets or capsules or open capsules.
- Inform patient not to receive live vaccines during therapy. Urge him to avoid people who have received such vaccines or to wear a protective mask when he's around them.
- Tell patient to report any serious or ongoing adverse reactions, especially neurologic abnormalities, to prescriber immediately.
- Caution patient not to engage in hazardous activities such as driving a car or using machines until the effects of the drug are known and patient is not experiencing confusion, dizziness, low blood pressure, somnolence, or tremors.
- Caution patient to avoid contact with people who have infections because drug causes immunosuppression, placing patient at increased risk for developing an infection.
- Urge patient to report any signs of infection, unexpected bleeding or bruising, or any other sign of bone marrow depression immediately.
- Tell patient that frequent laboratory tests may be needed during therapy. Emphasize that having these tests done is essential to continuing therapy.
- Advise patient to avoid exposure to direct sunlight and UV light and to wear sunscreen when outdoors because of increased risk for skin cancer.

- Advise patient not to take antacids at the same time as oral mycophenolate mofetil because some antacids can decrease drug's absorption.
- Tell patient to report dizziness, fainting, lack of energy, paleness, or unusual tiredness because dosage may have to be reduced or drug discontinued.
- Emphasize importance of follow-up care to monitor the drug's effectiveness and possible adverse effects because of the increased risk for cancer and infections as a result of immunosuppression. Inform patient of the need for periodic laboratory tests.
- Caution patient not to donate blood during therapy and for at least 6 weeks following discontinuation of drug. Tell male patients not to donate semen during therapy and for 90 days following discontinuation of drug.

# N O

**nadolol**

**Corgard**

## Class and Category

*Pharmacologic class:* Nonselective beta blocker

*Therapeutic class:* Antianginal, antihypertensive

## Indications and Dosages

- *To manage hypertension, alone or with other antihypertensives*

### **TABLETS**

**Adults.** *Initial:* 40 mg daily, increased by 40 to 80 mg as needed. *Maintenance:* 40 to 80 mg daily. *Maximum:* 320 mg daily.

- *To manage angina pectoris as long-term therapy*

### **TABLETS**

**Adults.** *Initial:* 40 mg daily, increased by 40 to 80 mg daily every 3 to 7 days, as needed. *Maintenance:* 40 to 80 mg daily. *Maximum:* 240 mg daily.

***DOSAGE ADJUSTMENT*** Interval possibly increased to every 24 to 36 hr if creatinine clearance is 31 to 50 ml/min; to every

24 to 48 hr if it's 10 to 30 ml/min; or to every 40 to 60 hr if it's less than 10 ml/min.

Route	Onset	Peak	Duration
P.O.	Up to 5 days	4 hr	24 hr

## Mechanism of Action

Selectively blocks  $\alpha_1$  and  $\beta_2$  receptors in vascular smooth muscle and  $\beta_1$  receptors in the heart, thereby reducing peripheral vascular resistance and blood pressure. Potent beta blockade decreases cardiac excitability, cardiac output, and myocardial oxygen demand, thus reducing angina. It also prevents reflex tachycardia, which typically occurs with most alpha blockers.

## Contraindications

Bronchial asthma; cardiogenic shock; heart failure; hypersensitivity to nadolol, other beta blockers, or their components; second- or third-degree AV block; sinus bradycardia

## Interactions

### DRUGS

*digoxin*: Increased risk of bradycardia

*epinephrine*: Possibly unresponsive to usual doses of epinephrine used to treat allergic reaction

*general anesthetics*: Increased risk of hypotension and myocardial depression

*insulin, oral antidiabetic drugs*: Possibly increased risk of hyperglycemia and hypoglycemia

*reserpine and other catecholamine-depleting drugs:*  
Increased risk of bradycardia and hypotension

## Adverse Reactions

**CNS:** Anxiety, depression, dizziness, drowsiness, fatigue, headache, paresthesia, syncope, vertigo, weakness, yawning

**CV:** **Bradycardia**, chest pain, edema, **heart block**, **heart failure**, **hypotension**, orthostatic hypotension, **ventricular arrhythmias**

**EENT:** Nasal congestion, taste perversion

**GI:** Dyspepsia, elevated liver enzymes, **hepatic necrosis**, **hepatitis**, jaundice, nausea, vomiting

**GU:** Ejaculation failure, impotence

**RESP:** Cough, dyspnea, wheezing

**SKIN:** Pruritus, scalp tingling

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Monitor neonate whose mothers are receiving nadolol at parturition for bradycardia, hypoglycemia, or other associated symptoms.

### LACTATION

- Drug is present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Use nadolol cautiously in patients with diabetes mellitus because it may prolong or worsen hypoglycemia by interfering with glycogenolysis.
- Anticipate that drug may worsen psoriasis; in patients with myasthenia gravis, it may worsen muscle weakness and diplopia.
- Be aware that chronic beta blocker therapy such as nadolol is not routinely withheld prior to major surgery because the benefits outweigh the risks associated with its use with general anesthesia and surgical procedures.

**WARNING** Withdraw drug gradually over 2 weeks, or as ordered, to avoid MI caused by unopposed beta stimulation or thyroid storm caused by underlying hyperthyroidism. Expect drug to mask tachycardia caused by hyperthyroidism.

## PATIENT TEACHING

- Teach patient how to take her radial pulse, and direct her to do so before each dose of nadolol.
- Instruct patient to notify prescriber if pulse rate falls below 60 beats/minute.
- Caution patient not to stop taking nadolol abruptly or change dosage. Tell her to take a missed dose as soon as possible unless it's within 8 hours of the next scheduled dose.
- Advise patient with diabetes to check blood glucose level often because nadolol may mask signs of hypoglycemia, such as tachycardia.
- Review signs of impending heart failure, and urge patient to notify prescriber immediately if they occur.

# nafcillin sodium

## Class and Category

*Pharmacologic class:* Penicillin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat infections caused by penicillinase-producing Staphylococcus aureus*

### I.V. INFUSION, I.V. INJECTION

**Adults.** 500 to 1,000 mg given over 5 to 10 for I.V. injection and over 30 to 60 min I.V. infusion every 4 hr. Duration of therapy is continued for at least 48 hr after patient is afebrile, asymptomatic, and cultures are negative. Severe infections require at least 14 days of therapy although endocarditis and osteomyelitis may require a longer time of therapy.

### I.M. INJECTION

**Adults.** 500 mg every 4 to 6 hr.

**Infants and children weighing less than 40 kg (88 lbs).** 25 mg/kg twice daily

**Neonates.** 10 mg/kg twice daily. Duration of therapy for all ages is continued for at least 48 hr after patient is afebrile, asymptomatic, and cultures are negative. Severe infections require at least 14 days of therapy although endocarditis and osteomyelitis may require a longer duration of therapy.

# Mechanism of Action

Binds to certain penicillin-binding proteins in bacterial cell walls, thereby inhibiting the final stage of bacterial cell wall synthesis. The result is cell lysis. Nafcillin's action is bolstered by its chemical composition; its unique side chain resists destruction by beta-lactamases.

# Incompatibilities

Don't mix nafcillin in same I.V. bag as aminoglycosides; they're chemically incompatible.

# Contraindications

Hypersensitivity to nafcillin, other penicillins, or their components

# Interactions

## DRUGS

*cyclosporine*: Increased risk of subtherapeutic cyclosporine levels

*tetracycline*: Possible antagonized bactericidal effect of nafcillin

*warfarin*: Decreased effectiveness of warfarin

# Adverse Reactions

**CNS**: Depression, fever, headache, **seizures**

**CV**: **Hypotension**, **vascular collapse**

**EENT**: Black or hairy tongue, **laryngospasm**, oral candidiasis, stomatitis

**GI:** Abdominal pain, cholestasis, diarrhea, elevated liver enzymes, nausea, **pseudomembranous colitis**, vomiting  
**GU:** **Acute kidney injury**, hematuria, interstitial nephritis, proteinuria, **renal tubular damage**, vaginitis  
**HEME:** **Agranulocytosis**, **bone marrow depression**, **leukopenia**, **neutropenia**  
**RESP:** **Bronchospasm**  
**SKIN:** **Exfoliative dermatitis**, pruritus, rash, urticaria  
**Other:** **Anaphylaxis**; **angioedema**; **hypokalemia**; injection-site pain, redness, and swelling; phlebitis; serum sickness-like reaction; skin sloughing; thrombophlebitis; tissue necrosis (severe)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Obtain body fluid or tissue samples for culture and sensitivity testing, as prescribed, and obtain test results, if possible, before giving nafcillin, as ordered.
- Expect to have the following laboratory tests ordered before and then periodically during nafcillin therapy: alkaline phosphatase, bilirubin, blood urea nitrogen, creatinine, liver enzymes, and urinalysis; this provides a

baseline and then allows monitoring for adverse effects stemming from nafcillin therapy.

- For direct I.V. administration, dilute in 15 to 30 ml of Sterile Water for Injection or Sodium Chloride Injection. Reconstituted solution are stable for 3 days at room temperature or 7 days under refrigeration and 90 days if frozen. Inject over 5 to 10 minutes.
- For intermittent I.V. infusion, reconstitute with 15 to 30 ml of Sterile Water for Injection or Sodium Chloride Injection prior to diluting further with intravenous solutions. Reconstituted solution are stable for 3 days at room temperature or 7 days under refrigeration and 90 days if frozen. Infuse over 30 to 60 minutes.
- For intramuscular injection, reconstitute with diluent recommended by manufacturer by adding 3.4 ml to the 1 g vial and 6.6 ml to the 2 g vial. All reconstituted vials have a concentration of 250 mg per ml. Inject by deep intragluteal injection immediately after reconstitution.
- Give nafcillin at least 1 hour before or after aminoglycosides, especially if patient has renal disease.
- When giving nafcillin to patient at risk for fluid overload or hypertension, be aware that each gram contains 2.5 mEq sodium.
- Watch for evidence of superinfection, such as oral candidiasis and pseudomembranous colitis, especially in elderly, immunocompromised, or debilitated patients who receive large doses of nafcillin. If profuse, watery diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold nafcillin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.

## PATIENT TEACHING

- Advise patient to notify prescriber if she experiences chills, fever, GI distress, or rash.
- Urge patient to tell prescriber if diarrhea develops, even 2 or more months after nafcillin therapy ends.

**nalbuphine hydrochloride**

# Nubain

## Class and Category

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

## Indications and Dosages

- *To relieve pain severe enough to require an opioid analgesic and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated*

### I.M., I.V., OR SUBCUTANEOUS INJECTION

**Adults weighing 70 kg (154 lb).** 10 mg every 3 to 6 hr, as needed. I.V. injection given over 3 to 5 min.

***DOSAGE ADJUSTMENT*** Dosage adjusted for patients weighing more or less than 70 kg, other medications which the patient may be receiving, severity of pain, and physical status of patient. For nontolerant adults, single maximum dose increased to 20 mg with a maximum total daily dose of 160 mg.

- *As adjunct to balanced anesthesia, for obstetrical analgesia during labor and delivery, and for preoperative and postoperative analgesia*

### I.V. INJECTION

**Adults.** 0.3 to 3 mg/kg over 10 to 15 min followed by 0.25 to 0.5 mg/kg, as needed.

---

Route	Onset	Peak	Duration
-------	-------	------	----------

Route	Onset	Peak	Duration
I.M.	In 15 min	1 hr	3-6 hr
I.V.	2-3 min	30 min	3-4 hr
SubQ	In 15 min	Unknown	3-6 hr

## Mechanism of Action

Binds with and stimulates kappa and mu opiate receptors in the spinal cord and higher levels in the CNS. In this way, nalbuphine alters the perception of and emotional response to pain.

## Incompatibilities

Don't give nalbuphine with diazepam or pentobarbital. Use separate I.V. line or flush line well before and after administration.

## Contraindications

Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment; gastrointestinal obstruction, including paralytic ileus; hypersensitivity to nalbuphine or any of its components; significant respiratory depression

## Interactions

### DRUGS

*5-HT<sub>3</sub> receptor antagonists, cyclobenzaprine; metaxalone; methylene blue (I.V.); selected psychiatric drugs such as buspirone, lithium, mirtazapine, nefazodone, trazodone, vilazodone; selective serotonin reuptake inhibitors;*

*serotonin-norepinephrine reuptake inhibitors; St. John's wort; tramadol; tricyclic antidepressants; triptans; tryptophan:* Increased risk of serotonin syndrome  
*anticholinergics:* Increased risk of severe constipation and urine retention  
*antipsychotics, anxiolytics, benzodiazepines, CNS depressants, general anesthetics, muscle relaxants, other opioids, other sedative/hypnotics, sedating antihistamines, tranquilizers, tricyclic antidepressants:* Increased risk of coma, severe respiratory depression, profound sedation, and death  
*diuretics:* Reduced effectiveness of diuretics  
*MAO inhibitors:* Risk of opioid toxicity or serotonin syndrome  
*neuromuscular blockers:* Increased risk of respiratory depression severity

## **ACTIVITIES**

*alcohol use:* Increased risk of coma, hypotension, profound sedation, and respiratory depression

## **Adverse Reactions**

**CNS:** Confusion, depression, dizziness, euphoria, fatigue, hallucinations, headache, nervousness, restlessness,

**seizures**, syncope, tiredness, weakness

**CV:** Hypertension, **hypotension**, tachycardia

**EENT:** Blurred vision, diplopia, dry mouth

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal cramps, anorexia, constipation, nausea, vomiting

**GU:** Decreased libido, decreased urine output, impotency, infertility, lack of menstruation, ureteral spasm

**RESP:** Dyspnea, **pulmonary edema**, **respiratory depression**, wheezing

**SKIN:** Diaphoresis, flushing, pruritus, rash, sensation of warmth, urticaria

**Other:** Injection-site burning, pain, redness, swelling, and warmth

## **Childbearing Considerations**

### **PREGNANCY**

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the newborn. Monitor neonate closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

### **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, monitor infant for excess sedation and respiratory depression.

## REPRODUCTION

- Chronic use of opioids may reduce fertility.

## Nursing Considerations

- Be aware that excessive use of opioids like nalbuphine may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely and for evidence of physical dependence.
- Know that chronic maternal use of nalbuphine during pregnancy can result in neonatal opioid withdrawal syndrome (NOWS), which may be life-threatening if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to opioid drugs like nalbuphine for a prolonged period while in utero.
- Use nalbuphine cautiously in patients taking other drugs that can cause respiratory depression.

**WARNING** Be aware that nalbuphine should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of nalbuphine to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Keep resuscitation equipment and naloxone readily available to reverse nalbuphine's effects, if needed.
- For direct I.V. injection used as an analgesic through an I.V. line with a compatible infusing solution, give drug slowly—no more than 10 mg over 3 to 5 minutes. Inject into free-flowing D<sub>5</sub>W, lactated Ringer's solution, or normal saline solution.
- Be aware that during prolonged use, a stool softener may be given to minimize constipation.

- Know that if patient is opioid-dependent, drug will usually not be discontinued abruptly. Monitor patient for withdrawal symptoms, such as abdominal cramps, anorexia, anxiety, backache, bone or joint pain, confusion, depression, diaphoresis, dysphoria, erythema, fear, fever, irritability, labile blood pressure and pulse, lacrimation, muscle spasms, myalgia, mydriasis, nasal congestion, nausea, opioid craving, piloerection, restlessness, rhinorrhea, sensation of crawling skin, sleep disturbances, tremor, uneasiness, vomiting, and yawning.

**WARNING** Know that many drugs may interact with opioids like nalbuphine to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect to do diagnostic testing. If confirmed, expect to administer corticosteroids and wean patient off nalbuphine, if possible.

**WARNING** Be aware that drug may obscure neurologic assessment findings if patient has a cerebral aneurysm, head injury, or increased intracranial pressure.

## **PATIENT TEACHING**

- Warn patient not to take drug longer than absolutely needed because excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death.
- Advise patient to avoid hazardous activities until nalbuphine's CNS effects are known.

**WARNING** Warn patient not to consume alcohol or take a benzodiazepine without prescriber knowledge while taking nalbuphine, as severe respiratory depression can occur and may lead to death. Inform patient about potentially fatal additive effects of combining a benzodiazepine with an opioid. Instruct patient to inform all prescribers of nalbuphine use.

- Counsel patient against making important decisions while receiving drug because it may cloud her judgment.
- Inform patient that long-term use of opioids like nalbuphine may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms to prescriber.
- Instruct patient to notify all prescribers of opioid use.

## naldemedine

### Symproic

## Class and Category

*Pharmacologic class:* Opioid receptor antagonist

*Therapeutic class:* Opioid antagonist of GI tract

## Indications and Dosages

- *To treat opioid-induced constipation in patients with chronic noncancer pain*

## TABLETS

**Adults.** 0.2 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	0.75 hr	Unknown

## Mechanism of Action

Functions as a peripherally acting mu-opioid receptor antagonist in the gastrointestinal tract to decrease the constipating effects of opioids.

## Contraindications

Gastrointestinal obstruction or increased risk of recurrent obstruction due to the potential for gastrointestinal perforation, hypersensitivity to naldemedine or its components

## Interactions

### DRUGS

*moderate CYP3A inhibitors such as aprepitant, atazanavir, diltiazem, erythromycin, fluconazole; P-glycoprotein inhibitors such as amiodarone, captopril, cyclosporine, quercetin, quinidine, verapamil; strong CYP3A inhibitors such as itraconazole:* Increased plasma naldemedine concentrations increasing risk of adverse reactions  
*other opioid antagonists:* Possible additive effect of opioid receptor antagonism and increased risk of opioid withdrawal

*strong CYP3A inducers such as carbamazepine, phenytoin, rifampin, St. John's wort:* Significant decrease in plasma naldemedine concentrations, which may decrease effectiveness

# Adverse Reactions

**GI:** Abdominal pain, diarrhea, gastroenteritis, **GI perforation**, nausea, vomiting

**RESP:** **Bronchospasm**

**SKIN:** Rash

**Other:** Opioid withdrawal

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Know that patients receiving opioids for less than a month may be less responsive to naldemedine therapy.
- Expect naldemedine to be discontinued if treatment with an opioid pain medication is discontinued.
- Monitor patient closely for abdominal pain. Know that gastrointestinal perforation has occurred with use of another peripherally acting opioid antagonist in patients with conditions that affect the gastrointestinal tract wall integrity, such as diverticular disease, infiltrative gastrointestinal

tract malignancies, Ogilvie's syndrome, peptic ulcer disease, or peritoneal metastases. Patients with Crohn's disease may be at increased risk for gastrointestinal perforation. Notify prescriber immediately if abdominal pain becomes persistent, severe, or worsens. Expect drug to be discontinued.

- Monitor patient for signs and symptoms of opioid withdrawal such as abdominal pain, chills, diarrhea, feeling cold, fever, flushing, hyperhidrosis, increased lacrimation, nausea, and vomiting. Patients who develop disruptions to the bloodbrain barrier may be at increased risk for opioid withdrawal or reduced analgesia.

## **PATIENT TEACHING**

- Inform patient that naldemedine should be discontinued if treatment with the opioid pain medication is discontinued.
- Tell patient that the most common side effects of naldemedine include abdominal pain, diarrhea, nausea, and vomiting.
- Advise patient to seek immediate emergency care if persistent, severe, or worsening abdominal pain occurs.
- Review the signs and symptoms of withdrawal with patient and tell her to notify prescriber if these symptoms occur.
- Inform women of childbearing age to notify prescriber if pregnancy occurs, as naldemedine does cross the placenta and may precipitate opioid withdrawal in the fetus.
- Inform mothers wishing to breastfeed that drug does appear in breast milk, increasing risk of adverse reactions for the nursing infant. Therefore, breastfeeding is not recommended.

**naloxegol**

**Movantik**

## **Class and Category**

*Pharmacologic class:* Opioid receptor antagonist  
*Therapeutic class:* Opioid antagonist of gastrointestinal tract

## Indications and Dosages

- *To treat opioid-induced constipation in patients with chronic noncancer pain*

### **TABLETS**

**Adults.** 25 mg once daily in the morning.

***DOSAGE ADJUSTMENT*** For patients unable to tolerate naloxegol at the normal dose, patients with renal impairment (creatinine clearance less than 60 ml/min), and patients taking moderate CYP3A4 inhibitor drugs such as diltiazem, erythromycin, or verapamil, dosage reduced to 12.5 mg once daily in the morning. If dose is well tolerated in patients with renal impairment, dosage increased to 25 mg once daily in the morning.

## Mechanism of Action

Functions as a peripherally acting mu-opioid receptor antagonist in tissues such as the gastrointestinal tract, thereby decreasing the constipating effects of opioids.

## Contraindications

Concomitant therapy with strong CYP3A4 inhibitors such as clarithromycin and ketoconazole, gastrointestinal obstruction or risk of recurrent obstruction due to potential for gastrointestinal perforation, hypersensitivity to naloxegol or its components

# Interactions

## DRUGS

*CYP3A4 inducers such as carbamazepine, rifampin, St. John's wort:* Decreased plasma naloxegol levels and effectiveness

*CYP3A4 inhibitors such as clarithromycin, diltiazem, erythromycin, itraconazole, ketoconazole, verapamil:* Increased plasma naloxegol levels, possibly increasing risk of adverse reactions including opioid withdrawal  
*other opioid antagonists:* Potential for additive effects and increased risk of opioid withdrawal

## FOOD

*grapefruit, grapefruit juice:* Increased plasma naloxegol levels

# Adverse Reactions

**CNS:** Headache

**GI:** Abdominal pain (may become severe), diarrhea, flatulence, nausea, vomiting

**SKIN:** Diaphoresis, rash, urticaria

**Other:** **Angioedema**, opioid withdrawal

# Childbearing Considerations

## PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.

- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Drug is not recommended for use in a mother who is breastfeeding.

## **Nursing Considerations**

- Expect all maintenance laxative therapy to be discontinued prior to patient starting naloxegol therapy but know that laxatives may be given, as ordered and if needed, after 3 days of naloxegol therapy.
- Know that tablet can be crushed to a powder and mixed with 4 ounces of water for patient who is unable to swallow tablet whole. Once mixed, patient must drink mixture immediately. To ensure that all of the dosage was ingested, refill same glass with 4 ounces of water, stir, and have patient drink contents again.
- Know that naloxegol may be administered through a nasogastric tube. Begin by flushing tube with 30 ml of water using a 60 ml syringe. Crush tablet to a powder in a container and mix with 60 ml of water. Draw up mixture using the 60 ml syringe and administer contents through the nasogastric tube. Add about 60 ml of water to same container used to prepare the dose. Draw up the water using the same 60 ml syringe and use all the water to flush the nasogastric tube and any remaining drug from the nasogastric tube into the stomach.
- Monitor patient for the development of persistent, severe, or worsening abdominal pain and/or diarrhea because gastrointestinal perforation has occurred with use of naloxegol. Symptoms generally occur within a few days of starting naloxegol therapy. If this type of abdominal pain occurs, withhold drug and notify prescriber. Know that drug may be restarted at a lower dose (12.5 mg daily), once symptoms have resolved and if drug is still needed.
- Monitor patient's reaction to naloxegol therapy, especially in patients who have taken opioids for at least 4 weeks prior to starting naloxegol, because sustained exposure to opioids may cause an increased response to naloxegol.
- Monitor patient for opioid withdrawal symptoms such as abdominal pain, anxiety, chills, diaphoresis, diarrhea, irritability, and yawning. Clusters of

these symptoms may occur with naloxegol therapy, especially if patient is receiving methadone or has a disruption in opioid therapy.

- Know that if opioid therapy is discontinued, naloxegol therapy should be discontinued.

## **PATIENT TEACHING**

- Tell patient to stop all maintenance laxative therapy prior to starting naloxegol therapy. Reassure him that laxatives may be used, if needed, after the first 3 days of therapy.
  - Instruct patient to take naloxegol at least 1 hour prior to the first meal of the day or 2 hours after the meal.
  - Tell patient who is unable to swallow tablet whole to crush it to a fine powder, mix it with 4 ounces of water and drink the mixture immediately. To ensure that all the drug has been ingested, have patient refill the same glass with 4 ounces of water again, stir, and drink entire content.
  - Teach caregiver how to administer drug via a nasogastric tube, if necessary.
  - Remind patient not to consume grapefruit or grapefruit juice while taking naloxegol.
  - Tell patient to notify prescriber if opioid therapy is discontinued.
  - Advise patient to inform prescriber of all medications being taken, including over-the-counter drugs and any new drug therapy begun once naloxegol therapy begins.
  - Instruct patient to stop drug and seek medical attention promptly if he develops persistent, severe, or worsening abdominal pain and/or diarrhea. Tell patient symptoms may occur a few days after starting treatment.
  - Warn patient that opioid withdrawal symptoms may occur while taking naloxegol and to notify prescriber.
  - Caution female patients of childbearing age to notify prescriber immediately if pregnancy is suspected or has occurred, as the drug may precipitate opioid withdrawal in a fetus, due to the undeveloped blood-brain barrier, as well as in the pregnant woman.
  - Advise females who might wish to breastfeed their infants not to do so, as the infant may experience opioid withdrawal symptoms because of the drug's presence in breast milk.
-

# naloxone hydrochloride

**Evzio, Narcan**

## Class and Category

*Pharmacologic class:* Opioid antagonist

*Therapeutic class:* Antidote

## Indications and Dosages

➤ *To treat known or suspected opioid overdose*

### **I.V., I.M., OR SUBCUTANEOUS INJECTION (NARCAN)**

**Adults.** 0.4 to 2 mg repeated every 2 to 3 min, as needed (in divided doses for children). If no response after 10 mg, patient may not have opioid-induced respiratory depression.

**Children.** 0.01 mg/kg as a single dose I.V.; if no improvement, 0.1 mg/kg given I.V. as a second dose. If I.V. route is not available, I.M. or subcutaneous routes may be used in divided doses.

### **I.M. OR SUBCUTANEOUS INJECTION (EVZIO)**

**Adults and children.** 2 mg, repeated every 2 to 3 min, as needed, until desired response occurs.

### **NASAL SPRAY (NARCAN)**

**Adults and children.** 2 mg (1 spray) to 4 mg (1 spray) repeated every 2 to 3 min, as needed, alternating nostrils with each dose.

- *To treat postoperative opioid-induced respiratory depression*

## **I.V. INJECTION**

**Adults.** *Initial:* 0.1 to 0.2 mg every 2 to 3 min until desired response occurs. Additional doses given every 1 to 2 hr, if needed, based on patient response.

**Children.** *Initial:* 0.005 to 0.01 mg every 2 to 3 min until desired response occurs. Additional doses given every 1 to 2 hr, as needed, based on patient response.

- *To reverse opioid-induced depression*

## **I.V., I.M., OR SUBCUTANEOUS INJECTION**

**Neonates.** *Initial:* 0.01 mg/kg every 2 to 3 min until desired response occurs. Additional doses given every 1 to 2 hr, if needed, based on patient response.

- *As adjunct to treat hypotension caused by septic shock*

## **I.V. INFUSION OR INJECTION**

**Adults.** Highly individualized.

Route	Onset	Peak	Duration
I.V.	1-2 min	5-15 min	45 min or longer
I.M., SubQ	2-5 min	5-15 min	45 min or longer
Nasal spray	1-3 min	Unknown	Unknown

## **Mechanism of Action**

Briefly and competitively antagonizes mu, kappa, and sigma receptors in the CNS, thus reversing analgesia, hypotension, respiratory depression, and sedation caused by most opioids. Mu receptors are responsible for analgesia, euphoria, miosis, and respiratory depression. Kappa receptors are responsible for analgesia and sedation. Sigma receptors control dysphoria and other delusional states.

## Incompatibilities

Don't mix naloxone with any other solution unless you verify that the drugs are compatible; drug is incompatible with alkaline, bisulfite, and metabisulfite solutions.

## Contraindications

Hypersensitivity to naloxone or its components

## Interactions

### DRUGS

*naloxegol*: Possibly increased risk of opioid withdrawal

## Adverse Reactions

**CNS:** Excitement, headache, irritability, nervousness, restlessness, **seizures**, tremor, violent behavior

**CV:** **Cardiac arrest**, hypertension (severe), **hypotension**, **ventricular fibrillation**, **ventricular tachycardia**

**EENT:** Nasal congestion, dryness, edema, inflammation, or pain (spray form); toothache

**GI:** Constipation, nausea, vomiting

**MS:** Muscle spasms, musculoskeletal pain

**RESP:** Dyspnea, **pulmonary edema**

**SKIN:** Diaphoresis, xeroderma

**Other:** Withdrawal symptoms

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug crosses the placental barrier and may precipitate withdrawal (maybe severe) in the fetus, as well as in the opioid-dependent mother.
- Monitor fetus for signs of distress after drug is given and until fetus and mother are stable.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding following drug administration.

## Nursing Considerations

- Keep resuscitation equipment readily available during naloxone administration.
- Administer parenteral Narcan brand by I.V. route whenever possible.
- Be aware that each Narcan nasal spray contains a single dose of naloxone and cannot be reused. Place patient in supine position to administer making sure device nozzle is inserted in either nostril of the patient. Provide support to the back of the patient's neck to allow the head to tilt back. Do not prime or test the device prior to administration. Press firmly on the device plunger to administer the dose. Remove the device nozzle from the patient's nostril after use and turn patient on side.
- Administer Evzio brand only by I.M. or subcutaneous route following printed instructions on the device label. Be aware that an electronic voice will guide user through each step but if it does not operate properly, the device will still deliver the intended dose. Once the red safety guard is

removed, drug must be used immediately or disposed of properly. Do not attempt to replace the red safety guard once it is removed.

- Know that upon actuation, Evzio brand will automatically insert the needle I.M. or subcutaneously, deliver 2 mg naloxone, and retract needle fully into its housing. Post injection, the black base locks in place, a red indicator appears in the viewing window, and the electronic visual and audible instructions signal that Evzio has delivered the intended dose.
- Give repeat doses as prescribed, depending on patient's response.
- Anticipate that rapid reversal of opioid effects can cause diaphoresis, nausea, and vomiting in addition to serious adverse effects such as hypotension, pulmonary edema, seizures, and ventricular arrhythmias. Monitor patient closely, especially patients at risk because of the presence of preexisting cardiovascular disorders or who are receiving drugs that cause similar adverse cardiovascular effects.

**WARNING** Watch for opioid withdrawal symptoms, especially when giving naloxone to opioid-dependent patient.

Symptoms may include abdominal cramps, anorexia, anxiety, backache, bone or joint pain, confusion, depression, diaphoresis, dysphoria, erythema, fear, fever, irritability, labile blood pressure and pulse, lacrimation, muscle spasms, myalgia, mydriasis, nasal congestion, nausea, opioid craving, piloerection, restlessness, rhinorrhea, sensation of crawling skin, sleep disturbances, tremor, uneasiness, vomiting, and yawning.

- Monitor patients in postoperative setting who have received naloxone because abrupt postoperative reversal of opioid depression after using naloxone may cause serious adverse effects. Excessive doses of naloxone in the postoperative setting have also caused significant reversal of analgesia and have caused patient to become agitated.
- Expect patient with hepatic or renal dysfunction to have increased circulating blood naloxone level.

## **PATIENT TEACHING**

- Inform patient or family that naloxone will reverse opioid-induced adverse reactions.
- Urge opioid-dependent patient to seek drug rehabilitation.
- Instruct family on how to administer naloxone by nasal spray, if prescribed for emergency use at home. Tell family to administer drug as quickly as possible if patient is unresponsive and an opioid overdose is suspected. Instruct family to lay patient on his back and administer the nasal spray into one nostril while providing support to the back of the neck to allow the head to tilt back. Tell them to use each nasal spray only one time. They should then turn the patient on his side and call for help by calling 911. Tell family to monitor patient while help is coming and to readminister nasal spray using a new NARCAN Nasal Spray every 2 to 3 minutes, if patient is not responding or responds and then relapses back into respiratory depression. Tell them to administer the nasal spray in alternate nostrils with each dose.

**naltrexone**

**Vivitrol**

**naltrexone hydrochloride**

## **Class and Category**

*Pharmacologic class:* Opioid antagonist

*Therapeutic class:* Opioid and alcohol blocker

## **Indications and Dosages**

- *To provide blockade of the effects of exogenously administered opioids*

### **TABLETS**

**Adults.** *Initial:* 25 mg, and if no withdrawal symptoms occur, dosage increased following day to 50 mg and then 50 mg given once daily thereafter. *Maintenance:* 50 mg every weekday with 100 mg dose on Saturday. Alternatively, 100 mg every other day or 150 mg every third day.

- *To prevent relapse to opioid dependence following opioid detoxification*

## **I.M. INJECTION (VIVITROL)**

**Adults.** 380 mg every 4 wk or once monthly.

- *As adjunct to treat alcoholism*

## **TABLETS**

**Adults.** 50 mg daily (up to 100 mg daily for some patients) for 12 wk.

## **I.M. INJECTION (VIVITROL)**

**Adults.** 380 mg every 4 wk or once monthly.

Route	Onset	Peak	Duration
P.O.	15–30 min	In 12 hr	24 hr*
I.M.	Unknown	2 hr	Unknown

\* For 50 mg; 48 hr for 100 mg; 72 hr for 150 mg.

## **Mechanism of Action**

Displaces opioid agonists from—or blocks them from binding with—delta, kappa, and mu receptors. Opioid receptor blockade reverses the euphoric effect of opioids. Naltrexone also inhibits the effects of endogenous opioids, thus reducing alcohol craving.

# Contraindications

Acute opioid withdrawal, concurrent therapy with opioid analgesics; dependency on opioids, including those currently maintained on opiate agonists (methadone) or partial agonists (buprenorphine); failure of the naloxone challenge test or has a positive urine screen for opioids; hypersensitivity to naltrexone or its components

# Interactions

## DRUGS

*disulfiram*: Increased risk of hepatotoxicity

*opioid analgesics*: Reversal of analgesic and adverse effects of these drugs, possibly withdrawal symptoms in opioid-dependent patients

*thioridazine*: Increased lethargy and somnolence

# Adverse Reactions

**CNS:** Abnormal thinking, agitation, anxiety, asthenia, chills, confusion, depression, dizziness, euphoria, fatigue, fever, hallucinations, headache, hyperkinesia, insomnia, irritability, malaise, nervousness, restlessness, somnolence, **suicidal ideation**, syncope, tremor

**CV:** Chest pain, edema, hypertension, palpitations, tachycardia

**EENT:** Blurred vision, burning eyes, conjunctivitis, dry mouth, eyelid swelling, hoarseness, pharyngitis, rhinitis, sneezing, tinnitus, vision abnormalities

**ENDO:** Hot flashes

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, elevated liver enzymes, GI ulceration, **hepatotoxicity** (excessive doses), nausea, vomiting

**GU:** Difficult ejaculation, urinary frequency

**HEME:** **Idiopathic thrombocytopenic purpura**

**MS:** Arthralgia, back pain or stiffness, joint stiffness, muscle cramps, myalgia

**RESP:** Cough, dyspnea, **eosinophilic pneumonia**, upper respiratory tract infection

**SKIN:** Increased sweating, pruritus, rash

**Other:** **Anaphylaxis**, injection-site reactions, such as bruising, erythema, induration, pain, tenderness; thirst

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use naltrexone cautiously in patients with hemophilia, severe hepatic failure, severe renal impairment, or thrombocytopenia.
- To avoid withdrawal symptoms, wait 7 to 10 days after last opioid dose, as prescribed, before starting naltrexone. Because urine testing isn't always conclusive, prepare patient for naloxone challenge test if there are any doubts about patient's abstinence.
- Give oral drug with antacids or food to decrease adverse GI reactions.
- Dilute parenteral form using only diluent supplied in carton. Inject intramuscularly in gluteal muscle using only needle supplied in carton.

Don't substitute any components for components in carton. Store entire dose pack in refrigerator; unrefrigerated drug can be stored at room temperature for no more than 7 days. Avoid administering as a subcutaneous injection because of increased risk of severe injection-site reactions.

- Inspect injection site for reactions, such as induration, redness, swelling, or tenderness. Ask if patient feels itching or pain at the site. Report any such findings to prescriber because abscesses and site necrosis may occur and require surgical intervention.

### **WARNING** Never give parenteral form intravenously.

- Be aware that patients who receive naltrexone and need pain management are more likely to have longer, deeper respiratory depression and histamine-release reactions (such as bronchoconstriction, facial swelling, generalized erythema, and itching) if given an opioid analgesic. Expect alternative analgesics to be used, such as conscious sedation with a benzodiazepine, general anesthesia, nonopioid analgesics, or regional anesthesia. If an opioid analgesic must be used, monitor patient closely.
- Watch patient closely for suicidal tendencies throughout naltrexone therapy.
- Anticipate that some patients may need treatment for up to 1 year.
- Be aware that after opioid detoxification, patients may have lowered tolerance to opioids that could result in life-threatening circulatory collapse or respiratory compromise if patient uses previously tolerated doses of opioids.

## **PATIENT TEACHING**

**WARNING** Caution patient against taking opioids during naltrexone therapy or in the future because she'll be more sensitive to them. In fact, strongly warn patient that taking large doses of heroin or any other opioid (including LAAM or methadone) while taking naltrexone could lead to coma, serious injury, or death.

- Explain that patient may have nausea after first injection but that it is usually mild and subsides within a few days. Most patients don't have nausea with repeat doses.

- Urge patient to seek immediate emergency help if serious hypersensitivity reactions occur such as difficulty breathing or swallowing.
- Tell patient to report adverse reactions promptly, especially abdominal pain, coughing, dyspnea, jaundice, and wheezing. Also, tell patient to report any injection-site reactions to prescriber, especially if reaction does not improve in 1 month following the injection or worsens as further treatment may be necessary.
- Caution patient to avoid performing hazardous activities, such as driving, until CNS effects of drug are known.
- Urge family or caregiver to watch patient closely for abnormal behaviors, including suicidal tendencies, even after patient stops taking naltrexone.
- Inform patient that naltrexone doesn't eliminate or diminish alcohol withdrawal symptoms.
- Urge patient to have comprehensive rehabilitation in addition to receiving naltrexone.
- Inform patient about nonopioid treatments for cough, diarrhea, and pain.
- Tell patient while taking drug she may not experience the expected effects from opioid-containing analgesic, antidiarrheal, or antitussive drugs.
- Warn patient that drug may cause liver damage. Tell her to report any signs of liver dysfunction, such as anorexia, digestive problems, or yellowing of skin or whites of her eyes.
- Instruct patient to carry medical identification that lists naltrexone therapy.

## **naproxen**

**EC-Naprosyn, Naprosyn**

## **naproxen sodium**

**Aleve, Anaprox, Anaprox DS, Flanax, Naprelan, Naprosyn-SR (CAN)**

## Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Analgesic

## Indications and Dosages

- *To relieve mild to moderate musculoskeletal inflammation, including ankylosing spondylitis, osteoarthritis, and rheumatoid arthritis*

### **DELAYED-RELEASE TABLETS, ORAL SUSPENSION, TABLETS (NAPROXEN)**

**Adults.** 250 to 500 mg twice daily. *Maximum:* 1,500 mg daily for limited periods, as prescribed.

### **DELAYED-RELEASE TABLETS (EC-NAPROSYN)**

**Adults.** 375 to 500 mg twice daily. *Maximum:* 1,500 mg daily.

### **E.R. TABLETS (NAPROXEN)**

**Adults.** 750 to 1,000 mg daily. *Maximum:* 1,500 mg daily.

### **TABLETS (NAPROXEN SODIUM)**

**Adults.** 275 to 550 mg twice daily. *Maximum:* 1,650 mg daily for limited periods, as prescribed.

### **SUPPOSITORIES (NAPROXEN SODIUM)**

**Adults.** 500 mg at bedtime in addition to daytime P.O. administration. *Maximum:* 1,500 mg daily (P.O. and suppository combined).

- *To relieve symptoms of juvenile rheumatoid arthritis and other inflammatory conditions in children*

## **ORAL SUSPENSION, TABLETS (NAPROXEN)**

**Children.** 10 mg/kg daily in divided doses twice daily.

- *To relieve symptoms of acute gouty arthritis*

## **ORAL SUSPENSION, TABLETS (NAPROXEN)**

**Adults.** *Initial:* 750 mg, then 250 mg every 8 hr until symptoms subside.

## **TABLETS (NAPROXEN SODIUM)**

**Adults.** *Initial:* 825 mg, then 275 mg every 8 hr until symptoms subside.

- *To relieve mild to moderate pain, including acute tendinitis and bursitis, arthralgia, dysmenorrhea, and myalgia*

## **ORAL SUSPENSION, TABLETS (NAPROXEN)**

**Adults.** *Initial:* 500 mg, then 250 mg every 6 to 8 hr, as needed. *Maximum:* 1,250 mg daily.

## **TABLETS (NAPROXEN SODIUM)**

**Adults.** *Initial:* 550 mg followed by 550 mg every 12 hr. Alternatively, 275 mg every 6 to 8 hr, as needed. *Maximum:* 1,375 mg for initial total daily dose; subsequent days total daily dose should not exceed 1,100 mg.

- *To relieve fever and mild to moderate musculoskeletal inflammation or pain*

## **CAPLET, CAPSULES, TABLETS (OTC NAPROXEN SODIUM)**

**Adults and adolescents.** 220 mg every 8 to 12 hr; or 440 mg and 220 mg 12 hr later. *Maximum:* 660 mg daily for 10 days unless directed otherwise.

**DOSAGE ADJUSTMENT** For patients over age 65, 220 mg every 12 hr. *Maximum:* 440 mg for 10 days unless directed otherwise.

Route	Onset	Peak	Duration
P.O. (naproxen)*	1 hr <sup>†</sup>	2–4 hr <sup>†‡</sup>	7–12 hr <sup>†</sup>
P.O. (naproxen sodium)*	30 min <sup>†</sup>	1 hr <sup>†‡</sup>	7–12 hr <sup>†</sup>

\* For antirheumatism, onset is in 14 days, peak is unknown, and duration is 2 to 4 wk.

† For analgesia.

‡ For gout, 1 to 2 days.

## Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local pain, swelling, and vasodilation. Thus, naproxen, an NSAID, reduces symptoms of inflammation and relieves pain. Antipyretic action probably stems from effects on the hypothalamus, which increases peripheral blood flow, causing vasodilation and heat dissipation.

## Contraindications

History of asthma, urticaria, or other allergic type reactions induced by aspirin or other NSAIDs; hypersensitivity to naproxen or its components; postoperatively for pain management after coronary artery bypass graft (CABG) surgery

## Interactions

## DRUGS

*angiotensin converting enzyme (ACE) inhibitors, angiotensin receptor blockers (ARBs):* Decreased antihypertensive effects; increased risk of renal dysfunction, especially in the elderly and those with impaired renal function or volume depletion

*aluminum hydroxide or magnesium oxide antacids, cholestyramine, sucralfate:* Possibly delayed absorption of naproxen

*anticoagulants, antiplatelets, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors:* Prolonged PT, increased risk of bleeding

*aspirin:* Decreased aspirin effectiveness with its antiplatelet effect taken to protect against CVA or MI; increased risk of GI adverse reactions compared to use of NSAID alone

*beta blockers:* Decreased antihypertensive effects of these drugs

*cyclosporine:* Increased risk of nephrotoxicity

*digoxin:* Increased blood digoxin level and risk of digitalis toxicity

*diuretics:* Decreased diuretic effectiveness

*lithium:* Increased risk of lithium toxicity

*methotrexate:* Increased risk of methotrexate toxicity

*other albumin-bound drugs:* Increased risk of interference with binding requiring dosage changes of these drugs

*other NSAIDs, salicylates:* Increased risk of GI toxicity

*pemetrexed:* Increased risk of pemetrexed-associated GI and renal toxicity, myelosuppression

*probenecid:* Increased risk of naproxen toxicity

## ACTIVITIES

*alcohol use, smoking:* Increased risk of naproxen-induced GI ulceration

# Adverse Reactions

**CNS:** Aseptic meningitis, chills, cognitive impairment, CVA, decreased concentration, depression, dizziness, dream disturbances, drowsiness, fever, headache, insomnia, light-headedness, malaise, seizures, vertigo

**CV:** Edema, heart failure, hypertension, MI, palpitations, tachycardia, vasculitis

**EENT:** Papilledema, papillitis, retrobulbar optic neuritis, stomatitis, tinnitus, vision or hearing changes

**ENDO:** Hyperglycemia, hypoglycemia

**GI:** Abdominal pain, anorexia, colitis, constipation, diarrhea, diverticulitis, dyspepsia, dysphagia, elevated liver enzymes, esophagitis, flatulence, gastritis, gastroenteritis, gastroesophageal reflux disease, GI bleeding and ulceration, heartburn, hematemesis, hepatitis, indigestion, melena, nausea, pancreatitis, perforation of intestines or stomach, stomatitis, vomiting

**GU:** Elevated serum creatinine level, glomerulonephritis, hematuria, infertility (in women), interstitial nephritis, menstrual irregularities, nephrotic syndrome, renal failure, renal papillary necrosis

**HEME:** Agranulocytosis, anemia, aplastic anemia, eosinophilia, granulocytopenia, hemolytic anemia, leukopenia, neutropenia, pancytopenia, thrombocytopenia

**MS:** Muscle weakness, myalgia

**RESP:** Asthma, dyspnea, eosinophilic pneumonitis, respiratory depression

**SKIN:** Alopecia, diaphoresis, ecchymosis, erythema multiforme, photosensitivity, pruritus, pseudoporphyria, purpura, rash, Stevens-Johnson syndrome systemic lupus erythematosus, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, hyperkalemia

## Childbearing Considerations

### PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding

### REPRODUCTION

- Drug may delay or prevent rupture of ovarian follicles, which may cause reversible infertility in some women.
- Drug should not be used in women who have difficulty conceiving or who are undergoing investigation of infertility.

## Nursing Considerations

- Be aware that NSAIDs like naproxen should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Know that the risk of heart failure increases with use of NSAIDs such as naproxen. NSAIDs should not be used in patients with severe heart failure but, if unavoidable, monitor patient for worsening of heart failure.
- Use naproxen with extreme caution in patients with a history of GI bleeding or ulcer disease because NSAIDs, such as naproxen, increase

risk of GI bleeding and ulceration. Expect to use naproxen for the shortest time possible in these patients.

- Use naproxen cautiously in patients with hypertension, and monitor blood pressure closely. Drug may cause hypertension or worsen it. Because of naproxen's sodium content, watch for fluid retention.
- Use naproxen cautiously in patients with heart failure, hypovolemia, liver dysfunction, renal dysfunction, salt depletion, or patients taking ACE inhibitors or ARBs and diuretics, and the elderly because of increased risk of renal decompensation. Be aware that naproxen is not recommended for patients with advanced renal disease.
- Monitor patient for serious GI tract bleeding, perforation, and ulceration, which may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber immediately.
- Rehydrate a dehydrated patient before giving drug. If patient has renal disease, monitor renal function closely during therapy.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk, especially if used in higher doses than recommended or for extended periods of time. These events have occurred even in patients who do not have a history or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, slurring of speech, shortness of breath, or weakness. If present, withhold naproxen, alert prescriber immediately, and provide supportive care as prescribed.

- Monitor patient—especially if elderly or receiving long-term naproxen therapy—for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting.
- Monitor liver enzymes because, in rare cases, elevations may progress to severe hepatic reactions, including fatal hepatitis, hepatic failure, or liver necrosis
- Monitor BUN and serum creatinine levels in elderly patients, patients taking diuretics or ACE inhibitors, and patients with heart failure, hepatic

dysfunction, or impaired renal function; naproxen may cause renal failure.

- Monitor CBC for decreased hemoglobin and hematocrit because drug may worsen anemia.

**WARNING** Know that if patient has bone marrow suppression or is receiving treatment with an antineoplastic drug, laboratory results (including WBC count) must be monitored; watch for evidence of infection because anti-inflammatory and antipyretic actions of naproxen may mask signs and symptoms, such as fever and pain.

- Assess patient's skin regularly for signs of rash or other hypersensitivity reaction because naproxen is an NSAID and may cause serious skin reactions without warning, even in patients with no history of NSAID sensitivity. At first sign of reaction, stop drug and notify prescriber.
- Assess drug effectiveness in ankylosing spondylitis, as evidenced by decreased morning stiffness, night pain, and pain at rest; in osteoarthritis: decreased joint pain or tenderness and increased ability to perform daily activities, mobility, and range of motion; in rheumatoid arthritis: decreased joint swelling and morning stiffness and increased mobility; in acute gouty arthritis: decreased heat, pain, swelling, and tenderness in affected joints.
- Tell prescriber if patient complains of vision changes; patient may need ophthalmic exam.

## **PATIENT TEACHING**

- Caution patient not to exceed recommended dosage, take for longer than directed, or take for more than 10 days without consulting prescriber because serious adverse reactions, such as a heart attack, heart failure, or stroke, may occur.
- Tell patient to swallow delayed-release tablets whole and not to break, chew, or crush them.
- Advise patient to take drug with food to reduce GI distress.
- Tell patient to take drug with a full glass of water and to remain upright for 15 to 30 minutes after taking it to prevent drug from lodging in esophagus and causing irritation.

- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to keep scheduled appointments with prescriber to monitor progress.
- Tell pregnant patient to avoid taking naproxen-containing products late in pregnancy.
- Explain that naproxen may increase risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, edema, shortness of breath, slurring of speech, unexplained weight gain, and weakness.
- Inform patient that naproxen may increase risk of serious adverse GI reactions; stress the importance of seeking immediate medical attention for such signs and symptoms as abdominal or epigastric pain, black or tarry stools, indigestion, or vomiting blood or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge her to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.
- Advise patient to consult prescriber before taking naproxen-containing OTC products if he has asthma, bleeding problems, heart or kidney disease, high blood pressure, or ulcers; a need for diuretic therapy; persistent stomach problems, such as heartburn, stomach pain, or upset stomach; or serious adverse effects from previous use of fever reducers or pain relievers.

## **naratriptan hydrochloride**

**Amerge**

### **Class and Category**

*Pharmacologic class:* Selective serotonin 5-HT receptor agonist

*Therapeutic class:* Antimigraine

# Indications and Dosages

- *To relieve acute migraine with or without aura*

## **TABLETS**

**Adults.** 1 or 2.5 mg as a single dose, repeated once in 4 hr as needed if headache returns or only partial relief obtained. *Maximum:* 5 mg daily.

***DOSAGE ADJUSTMENT*** For patients with mild to moderate hepatic or renal impairment, initial dose not to exceed 1 mg and maximum dosage reduced to 2.5 mg daily.

## **Mechanism of Action**

Binds to receptors on intracranial blood vessels and sensory nerves in trigeminal-vascular system to stimulate negative feedback, which halts serotonin release. Thus, naratriptan selectively constricts dilated and inflamed cranial vessels in the carotid circulation and inhibits production of proinflammatory neuropeptides.

## **Contraindications**

History of basilar or hemiplegic migraine, coronary artery disease, coronary artery vasospasm, stroke, or transient ischemic attack, hypersensitivity to naratriptan or its components, ischemic bowel disease, peripheral vascular disease, recent (within 24 hr) use of another 5-HT<sub>1</sub> agonist or an ergotamine-containing drug, severe hepatic or renal impairment, uncontrolled hypertension; Wolff-Parkinson-White syndrome or other cardiac accessory conduction pathway disorders

## **Interactions**

## DRUGS

*ergot-containing drugs*: Possibly additive or prolonged vasospastic reactions

*MAO inhibitors, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans*: Increased risk of serotonin syndrome

*other selective serotonin 5-HT receptor agonists (including triptans)*: Possibly additive risk of vasospastic reactions

## Adverse Reactions

**CNS**: Dizziness, drowsiness, fatigue, malaise, paresthesia

**CV**: **Chest heaviness, pain, or pressure**; hypertension; **hypertensive crisis**

**EENT**: Decreased salivation, otitis media, pharyngitis, photophobia, rhinitis, **throat tightness**

**GI**: Nausea, vomiting

**Other**: **Anaphylaxis, angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

**WARNING** Know that because naratriptan therapy can cause coronary artery vasospasm, monitor patient with coronary artery disease for signs or symptoms of angina while taking drug. Because naratriptan may also cause peripheral vasospastic reactions, such as ischemic bowel disease, monitor patient for abdominal pain and bloody diarrhea.

- Monitor patient for hypertension during naratriptan therapy even in patients with no history of hypertension because drug can cause significant elevation in blood pressure.
- Be prepared to perform complete neurovascular assessment in any patient who reports an unusual headache or who fails to respond to first dose of naratriptan.

**WARNING** Monitor patient closely for serotonin syndrome if she is taking naratriptan along with a selective serotonin reuptake inhibitor or serotonin norepinephrine reuptake inhibitor. Notify prescriber immediately if the patient exhibits agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting because serotonin syndrome can be life-threatening. Provide supportive care.

## PATIENT TEACHING

- Inform patient that naratriptan is used to treat acute migraine attacks and that it won't prevent or reduce the number of migraines.
- Tell patient if she has no relief from initial dose of naratriptan, instruct her to notify prescriber rather than taking another dose in 4 hours; she may need a different drug.
- Advise patient not to take more than maximum prescribed amount of naratriptan during any 24-hour period or to exceed 10 times or more instances of drug use each month. Overuse can cause headaches to

become worse or increase frequency of migraine attacks. Tell patient that if she is using naratriptan 10 times or more in a 30-day period she should notify prescriber, as drug may need to be discontinued. Also tell patient that she may need to be treated for withdrawal symptoms upon discontinuation.

- Advise patient to seek reevaluation by prescriber if she has more than four headaches during any 30-day period while taking naratriptan.
- Urge patient to inform all prescribers that she is receiving naratriptan therapy because serious drug interactions may occur.

## natalizumab

**Tysabri**

### Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Immunomodulator

### Indications and Dosages

- *To treat relapsing forms of multiple sclerosis including active secondary progressive disease, clinically isolated syndrome, and relapsing-remitting disease; to induce and maintain remission in moderately to severely active Crohn's disease with evidence of inflammation in patients who had inadequate response to or are unable to tolerate conventional therapy and inhibitors of tumor necrosis factor alpha*

### I.V. INFUSION

**Adults.** 300 mg infused over 1 hr every 4 wk.

Route	Onset	Peak	Duration
I.V.	Unknown	24 wk	Unknown

## Mechanism of Action

Inhibits migration of leukocytes from vascular space, increasing the number of circulating leukocytes. It does this by binding to integrins on the surface of leukocytes (except neutrophils) and inhibiting adhesion of leukocytes to their counter receptors. In multiple sclerosis, lesions probably occur when activated inflammatory cells, including T-lymphocytes, cross the blood-brain barrier.

## Contraindications

History of or presence of progressive multifocal leukoencephalopathy, hypersensitivity to natalizumab or its components

## Interactions

### DRUGS

*antineoplastics, immunomodulating agents, immunosuppressants, inhibitors of TNF- $\alpha$* : Increased risk of life-threatening infection

## Adverse Reactions

**CNS:** Depression, dizziness, **encephalitis**, fatigue, headache, **herpes encephalitis**, **meningitis**, **progressive multifocal leukoencephalopathy (PML)**, rigors, somnolence, **suicidal ideation**, vertigo

**CV:** Chest discomfort, peripheral edema

**EENT:** Acute retinal necrosis, sinusitis, tonsillitis, tooth infection

**GI:** Abdominal discomfort, cholelithiasis, diarrhea, elevated liver enzymes, gastroenteritis, **hepatotoxicity**, jaundice, nausea

**GU:** Amenorrhea; dysmenorrhea; irregular menstruation; ovarian cysts; UTI; urinary frequency, incontinence, or urgency; vaginitis

**HEME:** **Hemolytic anemia**

**MS:** Arthralgia, back or limb pain, joint swelling, muscle cramp

**RESP:** Cough, pneumonia, or other respiratory tract infection

**SKIN:** Dermatitis, night sweats, pruritus, rash, urticaria

**Other:** **Acute hypersensitivity reaction**, **anaphylaxis**, antibody formation, flu-like illness, herpes, immune reconstitution inflammatory syndrome, opportunistic infections, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Make sure patient has enrolled in the TOUCH prescribing program before giving natalizumab. Once patient has signed and initialed the TOUCH program enrollment form, place original signed form in the patient's medical record, send a copy to Biogen Idec, and give a copy to patient.
- Be aware that all atypical and serious opportunistic infections must be reported to Biogen Idec at 1-800-456-2255 and the FDA's MedWatch Program at 1-800-FDA-1088.
- Make sure patient with multiple sclerosis has had an MRI of the brain before starting natalizumab therapy. It will help distinguish evidence of multiple sclerosis from PML symptoms if they occur after therapy starts. Also know that the following three factors increase the risk of PML in patients treated with natalizumab: longer treatment duration, especially beyond 2 years; prior treatment with an immunosuppressant; and the presence of anti-JCV antibodies.
- Dilute natalizumab concentrate 300 mg/15 ml in 100 ml of normal saline injection. Gently invert solution to mix completely. Do not shake.
- Infuse drug immediately after dilution over 1 hour. After infusion, flush line with normal saline injection.
- Do not give natalizumab by I.V. push or bolus injection.
- Refrigerate drug and use within 8 hours if not used immediately.
- Observe patient during and for 1 hour after infusion for hypersensitivity reaction, evidenced by chest pain, dizziness, dyspnea, fever, flushing, hypotension, nausea, pruritis, rash, rigors, and urticaria. Reaction is more likely to occur if natalizumab therapy was interrupted. If hypersensitivity reaction occurs, notify prescriber; expect to withhold drug and provide supportive care.

**WARNING** Monitor patient closely for evidence of PML, a viral brain infection that may be disabling or fatal, because natalizumab increases the risk. Patients at increased risk include those who have received natalizumab for longer than 2 years, have had prior treatment with an immunosuppressant, and who have anti-JCV antibodies. If patient has unexplained neurologic changes, notify prescriber, withhold natalizumab, and prepare patient for a gadolinium-enhanced brain MRI and possible cerebrospinal fluid analysis, as ordered. Be aware that immune

reconstitution inflammatory syndrome may occur in patients who develop PML, even when drug has been discontinued. Monitor such patients for evidence of an overwhelming inflammatory response either to an opportunistic infection or the paradoxical symptomatic relapse of a prior infection despite it having been treated successfully in the past.

- Expect that patient will be reevaluated 3 months after first infusion, 6 months after first infusion, and every 6 months thereafter.
- Assess patient for evidence of infection because natalizumab may adversely affect immune system, increasing risk of infection. For example, the drug increases the risk for encephalitis and meningitis as well as acute retinal necrosis caused by herpes simplex and varicella zoster viruses that could become life-threatening or result in blindness. Other infections that may occur but are uncommon may include aspergilloma, Candida pneumonia, cryptococcal fungemia, or pulmonary mycobacterium avium intracellulare. If infection occurs, expect to obtain appropriate specimens for culture and sensitivity and to treat accordingly. If infection is serious, expect drug to be discontinued.
- Be aware that if patient with Crohn's disease has no therapeutic response after 12 weeks, natalizumab should be discontinued. If patient is on chronic oral corticosteroid therapy, expect tapering of oral corticosteroid dose to begin. If patient can't be tapered off oral corticosteroids within 6 months of starting natalizumab therapy, expect natalizumab to be discontinued. Likewise, if patient needs additional steroid use that extends beyond 3 months in a calendar year to control signs and symptoms of Crohn's disease, expect natalizumab to be discontinued.
- Assess patient's liver function regularly, as ordered, because natalizumab may cause significant liver damage. Expect drug to be discontinued if patient becomes jaundiced or liver enzymes become elevated.
- Ensure that when natalizumab is discontinued, patient completes the "Initial Discontinuation Questionnaire" and then has an appointment in 6 months to complete the "6-Month Discontinuation Questionnaire."

## **PATIENT TEACHING**

- Instruct patient on benefits and risks of natalizumab therapy, and provide medication guide for patient to read before therapy begins.

- Encourage patient to ask questions before signing the enrollment form.
- Emphasize need to report any worsening symptoms that persist over several days.
- Tell patient to inform all healthcare providers that he is receiving natalizumab therapy.
- Stress the need to have follow-up visits 3 months after first infusion, 6 months after first infusion, and at least every 6 months thereafter.
- Instruct patient to report evidence of allergic reaction.
- Instruct patient to avoid people who have infections. Advise him or family members to report confusion, cough, fever, headache, lower-back or side pain, or other unexplained signs and symptoms because they may indicate infection. Also tell patient to report decreased visual acuity or eye pain or redness, as these may be early signs of acute retinal necrosis caused by a herpes virus.
- Alert patient that signs and symptoms suggestive of PML can occur up to 6 months after drug is discontinued and should be reported immediately.

## nateglinide

**Starlix**

### **Class and Category**

*Pharmacologic class:* Meglitinide

*Therapeutic class:* Antidiabetic

### **Indications and Dosages**

- *As adjunct to control blood glucose level in type 2 diabetes mellitus*

### **TABLETS**

**Adults.** 120 mg three times daily within 1 to 30 min before meals.

## Mechanism of Action

Nateglinide stimulates the release of insulin from functioning beta cells of the pancreas. In patients with type 2 diabetes mellitus, a lack of functioning beta cells diminishes blood levels of insulin and causes glucose intolerance. By interacting with the adenosine triphosphatase (ATP)-potassium channel on the beta cell membrane, nateglinide prevents potassium ( $K^+$ ) from leaving the cell. This causes the beta cell to depolarize and the cell membrane's calcium channel to open. Consequently, calcium ( $Ca^{++}$ ) moves into the cell and insulin moves out of it. The extent of insulin release is glucose dependent; the lower the glucose level, the less insulin is secreted from the cell.

By promoting insulin secretion in patients with type 2 diabetes mellitus, nateglinide improves glucose tolerance.

Description

**DOSAGE ADJUSTMENT** Dosage reduced to 60 mg three times daily in patients with near-goal glycosylated hemoglobin (HbA<sub>1c</sub>) level.

Route	Onset	Peak	Duration
P.O.	20 min	1 hr	4 hr

## Contraindications

Hypersensitivity to nateglinide or its components

## Interactions

### DRUGS

*beta-blockers, clonidine, guanethidine, reserpine:* Possibly blunted signs and symptoms of hypoglycemia

*corticosteroids, phenytoin, rifampin, somatostatin analogues (lanreotide, octreotide), somatropin, St. John's wort, sympathomimetics, thiazide diuretics, thyroid products:* Possibly reduced hypoglycemic effects of nateglinide

*CYP2C9 substrate poor metabolizers, CYP2C9 inhibitors (amiodarone, fluconazole, sulfinpyrasone), glucomannan, guanethidine, gymnema sylvestre, MAO inhibitors, methandrostenolone and other anabolic hormones, nonselective beta-adrenergic blockers, NSAIDs, salicylates, somatostatin analogues:* Possibly additive hypoglycemic effects of nateglinide

### ACTIVITIES

*alcohol use:* Increased risk of hypoglycemia

# Adverse Reactions

**CNS:** Dizziness

**ENDO:** Hypoglycemia

**GI:** Cholestatic hepatitis, diarrhea, elevated liver enzymes, jaundice

**MS:** Accidental trauma, arthropathy, back pain

**RESP:** Bronchitis, cough, upper respiratory tract infection

**SKIN:** Pruritus, rash, urticaria

**Other:** Flu-like symptoms

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant such as hypoglycemia.

# Nursing Considerations

- Give nateglinide within 30 minutes before meals to reduce the risk of hypoglycemia.
- Monitor fasting glucose and HbA<sub>1c</sub> levels periodically, as ordered, to evaluate treatment effectiveness.
- Monitor patient often in event of fever, infection, surgery, or trauma because transient loss of glucose control may occur, requiring an

alteration in therapy.

- Know that patients who are poor metabolizers of CYP2CP substrates are at increased risk of developing hypoglycemia because they may experience an additive hypoglycemic effect from nateglinide therapy.

## PATIENT TEACHING

- Instruct patient to take nateglinide within 30 minutes before meals. Advise her to skip scheduled dose if she skips a meal to reduce the risk of hypoglycemia.
- Teach patient to measure blood glucose level and recognize hyperglycemia and hypoglycemia. Advise her to notify prescriber if blood glucose level is persistently abnormal.
- Inform patient that persistent consumption of alcohol, insufficient calorie intake, and strenuous exercise increase risk of hypoglycemia.
- Advise patient to monitor blood glucose level as prescribed and to keep follow-up appointments to monitor HbA<sub>1c</sub> level because drug may become less effective over time.
- Tell patient to inform all prescribers of nateglinide therapy and not to take any over-the-counter drugs, including herbal preparations, without prescriber's knowledge.

## nebivolol hydrochloride

**Bystolic**

## Class and Category

*Pharmacologic class:* Beta-adrenergic blocker

*Therapeutic class:* Antihypertensive

## Indications and Dosages

➤ *To treat hypertension*

## **TABLETS**

**Adults.** *Initial:* 5 mg once daily, increased at 2-wk intervals, as needed. *Maximum:* 40 mg once daily.

***DOSAGE ADJUSTMENT*** For patients with moderate hepatic impairment (Child-Pugh Class B) or moderate renal impairment (creatinine clearance less than 30 ml/min, initial dose reduced to 2.5 mg.

Route	Onset	Peak	Duration
P.O.	Unknown	1.5–4 hr	Unknown

## **Mechanism of Action**

May prevent arterial dilation and inhibit renin secretion, although precise mechanism of action isn't known. Negative chronotropic effects may slow resting heart rate, and negative inotropic effects may reduce cardiac output, myocardial contractility, and myocardial oxygen consumption during exercise or stress. All of these actions may work together to lower systolic and diastolic blood pressure.

## **Contraindications**

Cardiogenic shock, decompensated cardiac failure, heart block greater than first degree, hypersensitivity to nebivolol or its components, sick sinus syndrome (unless permanent pacemaker is in place), severe bradycardia, severe hepatic impairment

## **Interactions**

## DRUGS

*antiarrhythmias such as disopyramide, beta blockers, digoxin, selected calcium antagonists such as diltiazem and verapamil:* Increased effect on AV conduction and myocardial depression; increased risk of bradycardia  
*clonidine:* Further decrease in blood pressure; possible life-threatening rebound hypertension when clonidine is discontinued

*CYP2D6 inhibitors such as fluoxetine, paroxetine, propafenone, quinidine:* Increased hypertensive effect of nebivolol

*guanethidine, reserpine:* Possibly excessive reduction of sympathetic activity with resulting bradycardia or severe hypotension

## Adverse Reactions

**CNS:** Asthenia, dizziness, fatigue, headache, insomnia, paresthesia, somnolence, syncope, vertigo

**CV:** Allergic vasculitis, **AV block**, **bradycardia**, chest pain, hypercholesterolemia, hyperuricemia, **hypotension**, **MI**, peripheral edema, peripheral ischemia, Raynaud's phenomenon

**ENDO:** Hyperglycemia, mask symptoms of **hypoglycemia**

**GI:** Abdominal pain, diarrhea, elevated bilirubin and liver enzymes, nausea, vomiting

**GU:** **Acute renal failure**, elevated BUN level, erectile dysfunction

**HEME:** **Leukopenia**, **thrombocytopenia**

**RESP:** **Acute pulmonary edema**, **bronchospasms**, dyspnea

**SKIN:** Pruritus, psoriasis, rash, urticaria

**Other:** **Angioedema** (rare)

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LABOR & DELIVERY

- Monitor neonates of mothers who have been treated with drug during the third trimester of pregnancy for bradycardia, hypoglycemia, hypotension, and respiratory depression.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is not recommended for mothers who are breastfeeding because of the potential for serious adverse reactions, especially bradycardia.

# Nursing Considerations

- Know that patients with bronchospastic disease usually shouldn't be treated with beta blocker therapy such as nebivolol.
- Use nebivolol cautiously in patients with impaired hepatic or renal function.
- Expect to administer an alpha blocker, as ordered, before starting nebivolol therapy in patients with pheochromocytoma.
- Monitor blood pressure and pulse rate often, especially at start of nebivolol therapy and during dosage adjustments. Also monitor fluid intake and output and daily weight, and watch for evidence of heart failure, such as dyspnea, edema, fatigue, and jugular vein distention. If heart failure occurs or worsens, expect drug to be discontinued.
- Be aware that nebivolol shouldn't be stopped abruptly because MI, myocardial ischemia, severe hypertension, or ventricular arrhythmias may result.

- Expect nebivolol therapy to continue throughout the perioperative period of major surgery. However, monitor patient closely for protracted severe hypotension and difficulty restarting and keeping a heartbeat. Be prepared to administer a beta agonist such as dobutamine or isoproterenol, as ordered, to reverse the effects of nebivolol, if needed.
- Assess distal circulation and peripheral pulses in patient with peripheral vascular disease because drug can worsen it.
- Be aware that nebivolol may mask tachycardia from hyperthyroidism and that abrupt withdrawal can cause thyroid storm. Drug also can decrease blood glucose level, prolong or mask symptoms of hypoglycemia, promote hyperglycemia in patient with diabetes mellitus, or worsen psoriasis.
- Monitor patient closely for hypersensitivity reactions that may occur with beta blockers, especially patients with a history of severe anaphylactic reactions who may not be responsive to usual doses of epinephrine used to treat allergic reactions.
- Monitor neonates born to mothers treated with beta blockers such as nebivolol during the third trimester of pregnancy. Watch for bradycardia, hypoglycemia, hypotension, and respiratory depression.

## **PATIENT TEACHING**

- Instruct patient to take nebivolol exactly as prescribed and not to stop using it abruptly.
- Tell patient to weigh herself daily during nebivolol therapy and to notify prescriber if she gains more than 2 lb (0.9 kg) in 1 day or 5 lb (2.3 kg) in 1 week.
- Advise patient to rise slowly from a lying or seated position to minimize effects of orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to contact prescriber about bleeding or bruising, cough at night, dizziness, edema, rash, shortness of breath, or slow pulse rate.
- Advise diabetic patient to monitor her blood glucose level more often during nebivolol therapy because drug may mask symptoms of hypoglycemia.
- Inform patient with psoriasis that drug may aggravate this condition.

# nelfinavir mesylate

**Viracept**

## Class and Category

*Pharmacologic class:* Protease inhibitor

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus-1 (HIV-1) infection*

### ORAL POWDER, TABLETS

**Adults and adolescents.** 1,250 mg twice daily or 750 mg three times daily with food.

**Children ages 2 years and over.** 45 to 55 mg/kg twice daily or 25 to 35 mg/kg three times daily with food.

*Maximum:* 2,500 mg daily.

## Mechanism of Action

Selectively inhibits the virus-specific processing of specific polyproteins in HIV-1-infected cells to prevent formation of mature virions.

## Contraindications

Concomitant therapy with drugs highly dependent on CYP3A for clearance and for which elevated plasma

concentrations are associated with serious and/or life-threatening events such as alfuzosin, amiodarone, cisapride, dihydroergotamine, ergotamine, lovastatin, lurasidone, methylergonovine, midazolam (oral), pimozide, quinidine, rifampin, St. John's wort, sildenafil (for treatment of pulmonary arterial hypertension), simvastatin, or triazolam; hypersensitivity to nelfinavir or its components

## Interactions

### DRUGS

*atorvastatin, azithromycin, bosentan, colchicine, fluticasone, PDE5 inhibitors (sildenafil, tadalafil, vardenafil), quetiapine, rosuvastatin:* Increased concentration of these drugs, with possible increased effect and risk of adverse reactions

*carbamazepine, ethinyl estradiol, norethindrone, phenobarbital, phenytoin:* Decreased concentration of these drugs and nelfinavir, interfering with their effectiveness

*cyclosporine, sirolimus, tacrolimus:* Increased concentrations of these drugs and nelfinavir

*delavirdine:* Decreased concentrations of delavirdine and its effectiveness and increased concentration of nelfinavir, with possible increased effect and risk of adverse reactions

*indinavir, saquinavir:* Increased concentration of these drugs and nelfinavir, with possible increased effects and risk of adverse reactions

*methadone nevirapine, omeprazole, ritonavir:* Decreased concentration of these drugs and possible reduced effectiveness

*rifabutin:* Decreased concentration of nelfinavir and effectiveness and increased concentration of rifabutin, with possible increased effects and risk of adverse reactions

*salmeterol*: Increased risk of cardiovascular adverse events such as palpitations, QT prolongation, and sinus tachycardia

*trazodone*: Increased concentration of trazodone, with possible increased effect and risk of dizziness, hypotension, nausea, and syncope

*warfarin*: Possible changes in international normalized ratio (INR) requiring dosage change of warfarin

## Adverse Reactions

**CNS:** Anxiety, asthenia, depression, dizziness, emotional lability, fever, headache, hyperkinesia, insomnia, malaise, migraine, paresthesia, **seizures**, sleep disorder, somnolence, **suicidal ideation**

**CV:** Edema, hyperlipidemia, **prolonged QT interval**, **torsades de pointes**

**EENT:** Acute iritis, eye disorders, mouth ulcers, pharyngitis, rhinitis, sinusitis

**ENDO:** Fat redistribution, hyperglycemia, **hypoglycemia**

**GI:** Abdominal pain, anorexia, bilirubinemia, diarrhea, dyspepsia, elevated liver and pancreatic enzymes, epigastric pain, flatulence, **GI bleeding**, **hepatitis**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Kidney calculus, sexual dysfunction, urine abnormality

**HEME:** Anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**

**MS:** Arthralgia, arthritis, back pain, cramps, elevated creatine kinase, myalgia, myasthenia, myopathy

**RESP:** **Bronchospasms**, dyspnea

**SKIN:** Dermatitis including fungal, diaphoresis, folliculitis, maculopapular rash, pruritus, rash, urticaria

**Other:** **Dehydration**, generalized pain, **hypersensitivity reactions**, hyperuricemia, immune reconstitution

syndrome, **metabolic acidosis**

## **Childbearing Considerations**

### **PREGNANCY**

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- Drug may be present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## **Nursing Considerations**

- Administer nelfinavir with food.
- Know that for patients who cannot swallow tablets, the tablets may be placed in a small amount of water. Once dissolved, the mixture should be stirred well and consumed immediately. Add water to the container the tablets were mixed in and then have the patient swallow the rinse to ensure that the entire dose has been consumed.
- Prepare oral powder for consumption by mixing with a small amount of a dietary supplement, formula, milk, soy formula, or water. Have patient consume the mixture immediately, but know that it can be refrigerated up to 6 hours. Know that acidic foods or juices are not recommended for mixing the oral powder because it may result in a bitter taste. Do not reconstitute oral powder in its original container.
- Monitor patient's blood glucose level, because nelfinavir may cause changes in blood glucose levels. Other drugs in the same class as

nelfinavir have caused exacerbation of preexisting diabetes mellitus and new-onset diabetes mellitus, including diabetic ketoacidosis.

- Assess patients who have hemophilia type A or B closely for bleeding, because spontaneous skin hematomas and hemarthrosis have occurred with other protease inhibitors. In some cases, treatment with factor VIII was required.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including nelfinavir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Advise patient to avoid missing doses of nelfinavir. If she misses a dose, she should take it as soon as she remembers but should not double the next dose or take more than prescribed.
- Instruct patient or caregiver that drug must be taken with food.
- Inform patients who cannot swallow tablets that the tablets may be placed in a small amount of water. Once dissolved, the mixture should be stirred well and consumed immediately. Tell patient to then add water to the container the tablets were mixed in and swallow the rinse to ensure that the entire dose has been consumed.
- Instruct patient or caregiver on how to prepare oral powder for consumption by mixing with a small amount of a dietary supplement, formula, milk, soy formula, or water. Consumption of the mixture should occur immediately, but tell patient/caregiver that it can be refrigerated for up to 6 hours. Warn that acidic foods or juices are not recommended for mixing the oral powder because it may result in a bitter taste. The oral powder should not be reconstituted in its original container.
- Alert patient or caregiver that oral powder form contains phenylalanine and could be harmful to patients with phenylketonuria.
- Review signs and symptoms of hyperglycemia and hypoglycemia even if patient is not a diabetic. Urge patient to report any such findings to prescriber.
- Warn patients with hemophilia that nelfinavir may increase the risk of bleeding and to seek immediate medical attention if bleeding occurs.

- Inform patient that nelfinavir therapy may cause changes in his body appearance because of fat redistribution. Prepare him for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Inform women using oral contraceptives that an alternative or additional contraceptive should be used during nelfinavir therapy, because drug may make the oral contraceptive unreliable. Encourage women of childbearing age to report known or suspected pregnancy.
- Alert mothers that breastfeeding is not recommended during nelfinavir therapy.
- Tell patient to report all drugs being taken, including over-the-counter medications and herbals, as serious drug interactions may occur. Advise patient not to begin any new drug therapy without first checking with prescriber.
- Warn male patients who are taking a PDE5 inhibitor to discuss use with prescriber before continuing and, if used, to seek immediate medical attention for prolonged penile erection.
- Inform patient that the most common side effect of nelfinavir is diarrhea, which can be controlled with over-the-counter drugs such as loperamide if prescriber so advises.

**nesiritide**

**Natrecor**

## **Class and Category**

*Pharmacologic class:* Human B-type natriuretic peptide

*Therapeutic class:* Vasodilator

## **Indications and Dosages**

- *To reduce dyspnea at rest or with minimal activity in patients with acute decompensated congestive heart failure*

## I.V. INFUSION, I.V. INJECTION

**Adults.** 2 mcg/kg bolus given over 1 min and then continuous infusion of 0.01 mcg/kg/min with dosage adjustment upward, as needed, no more frequently than every 3 hr. *Maximum:* 0.03 mcg/kg/min.

**DOSAGE ADJUSTMENT** For patients starting therapy with a systolic blood pressure below 110 mm Hg or for patients recently treated with afterload reducers, bolus dosage may need to be eliminated. For patients developing hypotension during treatment, dosage reduced or drug discontinued. If drug restarted after patient has stabilized, dose reduced by 30% with no initial bolus given.

Route	Onset	Peak	Duration
I.V.	In 15 min	1 hr	3 hr

## Mechanism of Action

Binds to guanylate cyclase receptor of vascular smooth muscle. This action increases intracellular levels of cyclic guanosine monophosphate, which leads to arterial and venous smooth muscle cell relaxation. Ultimately, nesiritide reduces pulmonary capillary wedge pressure and systemic arterial pressure in patients with congestive heart failure, which decreases the heart's workload and subsequently relieves dyspnea.

## Incompatibilities

Don't infuse nesiritide through same I.V. line as bumetanide, enalaprilat, ethacrynate sodium, furosemide, heparin, hydralazine, or insulin because these drugs are chemically and physically incompatible with nesiritide. Don't infuse drugs that contain the preservative sodium metabisulfite through same I.V. line as nesiritide.

## Contraindications

Cardiogenic shock, hypersensitivity to nesiritide or its components, persistent systolic blood pressure less than 100 mm Hg

## Interactions

### DRUGS

*ACE inhibitors, afterload reducers, angiotensin II receptor blockers:* Increased risk of symptomatic hypotension

## Adverse Reactions

**CNS:** Anxiety, dizziness, headache, insomnia

**CV:** Angina, **bradycardia**, **hypotension**, **PVCs**, **ventricular tachycardia**

**GI:** Abdominal pain, nausea, vomiting

**GU:** Elevated serum creatinine level, worsening of renal function

**MS:** Back pain

**Other:** **Anaphylaxis and other hypersensitivity reactions**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is excreted in breast milk.
- Once stabilized, patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Be aware that nesiritide isn't recommended for patients suspected to have low cardiac filling pressures or patients for whom vasodilating drugs aren't appropriate, such as those with constrictive pericarditis, pericardial tamponade, obstructive or restrictive cardiomyopathy, significant valvular stenosis, or other conditions in which cardiac output depends on venous return.

- Reconstitute 1.5-mg vial by adding 5 ml diluent removed from a 250-ml plastic I.V. bag containing preservative-free D<sub>5</sub>W, normal saline solution, dextrose 5% in half-normal (0.45) saline solution, or dextrose 5% in quarter-normal (0.2) saline solution.
- Don't shake vial. Rock it gently so all surfaces, including the stopper, are in contact with diluent to ensure complete reconstitution. Inspect drug for discoloration and particulate matter; if present, discard drug.
- Withdraw entire contents of reconstituted solution and add it to 250-ml plastic I.V. bag used to withdraw diluent to yield a solution of about 6 mcg/ml. Invert I.V. bag several times to ensure complete mixing.
- After preparing infusion bag, withdraw bolus volume from infusion bag and give it over about 60 seconds. Immediately after bolus, infuse drug at 0.1 ml/kg/hr, which will deliver 0.01 mcg/kg/min.
- Prime I.V. tubing with 25 ml of solution before connecting to the I.V. line and before administering the bolus dose or starting the infusion.

- Flush the I.V. line between doses of nesiritide and incompatible drugs.
- Know that because nesiritide binds to heparin and therefore could bind to the heparin lining of a heparin-coated catheter, it should not be given through a central heparin-coated catheter.
- Store reconstituted vials at room temperature (20° to 25°C [68° to 77°F]) or refrigerate (2° to 8°C [36° to 46°F]) for up to 24 hours.
- Discard the reconstituted solution after 24 hours because nesiritide contains no antimicrobial preservatives.
- Monitor blood pressure and heart rate and rhythm frequently during therapy. If hypotension occurs, notify prescriber and expect to reduce dosage or discontinue the drug. Implement measures to support blood pressure as prescribed.
- Assess patient's breath sounds and respiratory depth, quality, rate, and rhythm frequently during drug therapy.
- Monitor serum creatinine level during and after therapy has been completed. Notify prescriber of abnormal results because nesiritide may decrease renal function.

**WARNING** Monitor patient for serious hypersensitivity reactions following nesiritide administration. Reactions can become serious, requiring emergency supportive care.

- Store unopened drug at controlled room temperature or refrigerate. Keep in carton until time of use.

## **PATIENT TEACHING**

- Instruct patient to notify you or another nurse if she becomes dizzy because this may indicate hypotension.
- Reassure patient that her blood pressure, breathing, and heart rate will be monitored frequently.
- Emphasize importance of reporting an allergic reaction immediately.

# nevirapine

## Viramune, Viramune XR

### Class and Category

*Pharmacologic class:* Non-nucleoside reverse transcriptase inhibitor (NNRTI)

*Therapeutic class:* Antiretroviral

### Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV-1) infection*

#### ORAL SUSPENSION, TABLETS

**Adults and adolescents 16 years and older.** 200 mg (immediate-release tablets) once a day for 14 days.

*Maintenance:* 200 mg (immediate-release tablets or oral suspension) twice daily. *Maximum:* 200 mg/dose.

**Infants 15 days and over and children.** 150 mg/m<sup>2</sup> once a day for 14 days. *Maintenance:* 150 mg/m<sup>2</sup> twice daily.

*Maximum:* 200 mg/dose.

#### E.R. TABLETS

**Adults.** 400 mg once daily after an initial dose of 200 mg (immediate-release tablets) given for 14 days.

**Children age 6 and over with a body surface area (BSA) 1.17 m<sup>2</sup> or greater.** 400 mg once a day after an

initial dose of 150 mg/m<sup>2</sup> (immediate-release tablets) given once a day for 14 days.

**Children age 6 and over with a BSA 0.84 to 1.16 m<sup>2</sup>.**

300 mg once a day after an initial dose of 150 mg/m<sup>2</sup> (immediate-release tablets) given once a day for 14 days.

**Children age 6 and over with a BSA 0.58 to 0.83 m<sup>2</sup>.**

200 mg once a day after an initial dose of 150 mg/m<sup>2</sup> (immediate-release tablets) given once a day for 14 days.

**DOSAGE ADJUSTMENT** For patient experiencing a mild to moderate rash without constitutional symptoms during the 14-day lead-in period of 200 mg/day for adults and 150 mg/m<sup>2</sup> for infants and children using immediate-release formulation, maintenance dosage not increased to twice daily or extended-release tablets administered until rash is resolved. If rash not resolved after 28 days of taking nevirapine once daily, drug discontinued. For adult patient with end-stage renal disease receiving dialysis, an additional dose of 200 mg immediate release formulation given following each dialysis session.

## Mechanism of Action

Binds directly to reverse transcriptase and blocks the RNA-dependent and DNA-dependent DNA polymerase activities by causing a disruption of the enzymes' catalytic site.

## Contraindications

Hypersensitivity to nevirapine or its components, moderate to severe hepatic impairment, use as part of nonoccupational and occupational postexposure prophylaxis regimens

## Interactions

## DRUGS

*amiodarone, boceprevir, cisapride, clarithromycin, cyclophosphamide, cyclosporine, diltiazem, disopyramide, efavirenz, ergotamine, ethinyl estradiol, fentanyl, ketoconazole, indinavir, itraconazole, lidocaine, lopinavir/ritonavir, nelfinavir, nifedipine, norethindrone, saquinavir/ritonavir, sirolimus, tacrolimus, telaprevir, verapamil*: Possible decreased concentration of these drugs with possible decreased effectiveness

*atazanavir/ritonavir, fosamprenavir, fosamprenavir/ritonavir*: Decreased concentration with these drugs with possible decreased effectiveness and increased nevirapine concentration with possible risk of prolonged action and adverse reactions

*carbamazepine, clonazepam, ethosuximide*: Decreased concentrations of these drugs and nevirapine with possible decreased effectiveness

*fluconazole*: Increased nevirapine concentration with possible increased risk of prolonged action and adverse reactions

*methadone*: Decreased concentration of methadone, increasing risk of opiate withdrawal

*other NNRTI agents such as delavirdine, etravirine,*

*rilpivirine*: Possible plasma concentration alteration

*rifabutin*: Increased concentration of rifabutin with possible risk of prolonged action and adverse reactions

*rifampin*: Decreased concentration of nevirapine with possible decreased effectiveness

*warfarin*: Possible increased concentration of warfarin with possible alteration in anticoagulation

## Adverse Reactions

**CNS:** Fatigue, fever, headache, **hepatic encephalopathy**, malaise, paresthesia, somnolence

**EENT:** Conjunctivitis, oral lesions, ulcerative stomatitis

**ENDO:** Cushingoid appearance, fat redistribution

**GI:** Abdominal pain, anorexia, **cholestatic and fulminant hepatitis**, diarrhea, elevated liver enzymes, **hepatic failure or necrosis**, **hepatotoxicity**, hyperbilirubinemia, jaundice, liver tenderness, nausea, vomiting

**GU:** Renal dysfunction

**HEME:** Anemia, **granulocytopenia**, **leukopenia**, **neutropenia**, **prolonged partial thromboplastin time**, **thrombocytopenia**

**MS:** Arthralgia, joint and muscle aches, myalgia, **rhabdomyolysis**

**SKIN:** Blisters, bullous eruptions, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, drug withdrawal symptoms, flu-like symptoms, **hypophosphatemia**, immune reconstitution syndrome, lymphadenopathy, organ dysfunction

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug causes fetal harm.
- Chronic use of drug can cause severe hepatic dysfunction, including fatalities, in pregnant women receiving chronic nevirapine therapy as part of combination treatment for HIV-1 infection.
- Pregnant women with CD4+ cell counts greater than 250 cells/mm<sup>3</sup> should not be started on the drug.

- Use with extreme caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- Drug is excreted in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## **REPRODUCTION**

- Drug may reduce fertility in females of reproductive potential. It is not known if these effects on fertility are reversible

## **Nursing Considerations**

- Know that nevirapine should never be used as monotherapy, because a resistant virus emerges rapidly.
- Check patient's liver enzymes before initiating nevirapine therapy, as ordered and regularly thereafter.
- Shake oral suspension container gently prior to measuring dose. Use an oral syringe or dosing cup to measure dosage, especially if volume to be administered is 5 ml or less. If a dosing cup is used, thoroughly rinse the cup with water and have patient drink the rinse.
- Expect to strictly follow the initial 14-day period of once-daily dosing to decrease the incidence of a rash. If a mild to moderate rash develops, know that the 14-day once-daily dosing period should be extended to as long as 28 days total. However, if rash continues to persist after 28 days of therapy, expect drug to be discontinued. Report a severe rash or any rash that is accompanied by other signs and symptoms to prescriber immediately and expect drug to be discontinued.
- Be aware that the oral suspension formulation is not recommended for use initially in adult female patients with a CD4+ cell count greater than 250 cells/mm<sup>3</sup> or adult male patients with a CD4+ cell count greater than 400 cells/mm<sup>3</sup>, because of risk for serious or life-threatening hepatotoxicity.

- Know that if nevirapine therapy is interrupted for more than 7 days, the initial dosage regimen using the immediate-release formulation can be expected to be repeated for the first 14 days.

**WARNING** Monitor patient closely during the first 18 weeks of therapy to detect potentially life-threatening hepatotoxicity or skin reactions. Know that the greatest risk occurs during the first 6 weeks of therapy; patients at greatest risk include females and those having higher CD4+ cell counts at the initiation of therapy. Women with CD4+ cell count greater than 250 cells/mm<sup>3</sup> are at greatest risk. Patients coinfectd with hepatitis B or C and/or who have increased transaminase levels at the start of therapy are at a greater risk of symptomatic events that may appear 6 weeks or more after starting nevirapine therapy. However, monitor all patients at all times, as these adverse reactions have also occurred in patients not considered at risk. Monitor patient closely for rash that may be combined with signs and symptoms of hepatitis that may progress to hepatic failure. If patient develops signs and symptoms of hepatitis or presents with increased transaminases accompanied with a rash or systemic symptoms such as blisters, conjunctivitis, facial edema, fatigue, fever, joint or muscle aches, malaise, oral lesions, or renal dysfunction, notify prescriber immediately; check transaminases levels, as ordered; and expect nevirapine to be discontinued.

- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including nevirapine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Advise patient to avoid missing doses of nevirapine. If she misses a dose, she should take it as soon as she remembers, but should not double the next dose or take more than prescribed.
- Tell patient prescribed oral suspension to shake oral suspension container gently prior to measuring dose. Use an oral syringe or dosing cup to measure dosage, especially if volume to be administered is 5 ml or less. If a dosing cup is used, tell patient to thoroughly rinse the cup with water and drink the rinse.

**WARNING** Inform patient about severe liver disease that may occur with nevirapine. Tell her to report signs and symptoms of liver disease such as acholic stools, anorexia, fatigue, malaise, nausea, tenderness over liver area, or yellowing of skin or whites of the eyes, and to seek immediate medical attention.

- Stress importance of being compliant with tests ordered to screen for adverse effects of nevirapine therapy.

**WARNING** Advise patient that nevirapine therapy may cause severe hypersensitivity or skin reactions. Tell her to report a rash, especially if it is accompanied by blisters, conjunctivitis, facial edema, fatigue, fever, joint or muscle aches, liver problems, or oral lesions, and to seek immediate medical attention.

- Inform patient that nevirapine therapy may cause changes in her body appearance because of fat redistribution. Prepare her for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Inform female patients of childbearing age that nevirapine may impair fertility.

- Alert mothers that breastfeeding is not recommended during nevirapine therapy.
- Tell patient to report all drugs being taken, including over-the-counter medications and herbals, as serious drug interactions may occur. Advise patient not to begin any new drug therapy without first checking with prescriber.

## nicardipine hydrochloride

**Cardene, Cardene IV, Cardene SR**

### Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antianginal, antihypertensive

### Indications and Dosages

➤ *To manage chronic stable angina pectoris*

#### **CAPSULES**

**Adults.** 20 mg three times daily, increased every 3 days, as needed. *Maintenance:* 20 to 40 mg three times daily.

➤ *To manage hypertension*

#### **CAPSULES**

**Adults.** 20 mg three times daily, increased every 3 days, as needed. *Maintenance:* 20 to 40 mg three times daily.

#### **E.R. CAPSULES**

**Adults.** 30 mg twice daily.

- *To control hypertension when oral therapy is not desirable or feasible*

## I.V. INFUSION

**Adults.** *Initial:* 5 mg/hr by continuous infusion; increased by 2.5 mg/hr every 5 to 15 min, as prescribed. *Maximum:* 15 mg/hr.

**DOSAGE ADJUSTMENT** For patients with impaired liver function initial dose reduced to 20 mg twice daily with slow titration. For patients with impaired renal function, initial dosage of 20 mg three times daily kept but titration done slower.

Route	Onset	Peak	Duration
P.O.	20 min	1-2 hr	Unknown
P.O. (E.R.)	20 min	1-2 hr	12 hr
I.V.	Immediate	Unknown	Unknown

## Mechanism of Action

May slow extracellular calcium movement into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and interfering with calcium release from the sarcoplasmic reticulum. By decreasing the intracellular calcium level, nicardipine inhibits smooth-muscle cell contraction and dilates coronary and systemic arteries. As with other calcium channel blockers, these actions lead to decreased myocardial oxygen requirements and reduced afterload, blood pressure, and peripheral resistance.

# Incompatibilities

Don't mix nicardipine with sodium bicarbonate or lactated Ringer's solution, and don't administer through same I.V. line.

# Contraindications

Advanced aortic stenosis, hypersensitivity to nicardipine and its components

# Interactions

## DRUGS

*cimetidine*: Increased nicardipine bioavailability

*cyclosporine*: Increased plasma cyclosporine levels

*digoxin*: Transiently increased blood digoxin level, increased risk of digitalis toxicity

*fentanyl*: Possibly severe hypotension

*tacrolimus*: Increased plasma tacrolimus levels

## FOODS

*grapefruit, grapefruit juice*: Possibly increased bioavailability of nicardipine

*high-fat meals*: Decreased blood nicardipine level

# Adverse Reactions

**CNS:** Anxiety, asthenia, ataxia, confusion, dizziness, drowsiness, headache, nervousness, paresthesia, psychiatric disturbance, syncope, tremor, weakness

**CV:** **Bradycardia**, chest pain, exacerbation of angina (chronic therapy), **heart failure**, **hypotension**, orthostatic

hypotension, palpitations, peripheral edema, tachycardia

**EENT:** Altered taste, blurred vision, dry mouth, epistaxis, gingival hyperplasia, pharyngitis, rhinitis, tinnitus

**ENDO:** Gynecomastia, hyperglycemia

**GI:** Anorexia, constipation, diarrhea, elevated liver enzymes, indigestion, nausea, thirst, vomiting

**GU:** Dysuria, nocturia, polyuria, sexual dysfunction, urinary frequency

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Joint stiffness, muscle spasms

**RESP:** Bronchitis, cough, **decreased oxygen saturation**, upper respiratory tract infection

**SKIN:** Dermatitis, diaphoresis, **erythema multiforme**, flushing, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, urticaria

**Other:** **Hypokalemia**, injection-site irritation, weight gain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as transient fetal heart rate decelerations and neonatal hypotension when drug is given intravenously.
- Drug may also cause maternal harm causing such adverse reactions as dizziness, flushing, headache, hypotension, nausea, and reflex tachycardia when administered intravenously.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug may slow or halt labor when given intravenously.
- Drug increases risk for postpartum hemorrhage for mother when given intravenously.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended

## Nursing Considerations

- Check blood pressure and pulse rate before nicardipine therapy begins, during dosage changes, and periodically throughout therapy. During prolonged therapy, periodically assess ECG tracings for arrhythmias and other changes.
- Dilute each 25-mg ampule of nicardipine with 240 ml of solution to yield 0.1 mg/ml. Mixture is stable at room temperature for 24 hours.
- Know that if using premixed nicardipine for intravenous infusion, strength must be checked carefully because drug comes as single strength (20 mg nicardipine in 200 ml of solution, providing 0.1 mg/ml) or double strength (40 mg nicardipine in 200 ml of solution, providing 0.2 mg/ml).
- Administer continuous infusion by I.V. pump or controller, and adjust according to patient's blood pressure, as prescribed. Be aware that the I.V. dosage should be titrated slowly in patients receiving a beta blocker and in patients with heart failure or significant left ventricular dysfunction because of possible negative inotropic effects. Also, patients with renal impairment require a more gradual titration when given drug intravenously.
- Administer drug through large peripheral veins or central veins to reduce the possibility of extravasation, local irritation, phlebitis, swelling, vascular impairment, or venous thrombosis. Change peripheral I.V. site every 12 hours, if feasible, to minimize these effects.
- Give first dose of oral nicardipine 1 hour before stopping I.V. infusion, as ordered.
- Monitor fluid intake and output and daily weight for signs of fluid retention, which may precipitate heart failure. Also assess for signs of heart failure, such as crackles, dyspnea, jugular vein distention, peripheral edema, and weight gain.
- During prolonged therapy, expect to periodically monitor liver and renal function test results. Anticipate drug dosage to be titrated slowly in these patients. Expect elevated liver enzymes to return to normal after drug is discontinued.

- Monitor patient with angina for increases in duration, frequency, or severity of symptoms because with chronic use of oral nicardipine (rarely with I.V. administration), exacerbation of angina may occur.
- Monitor serum potassium level during prolonged therapy. Hypokalemia increases the risk of arrhythmias.
- Monitor patients who take a beta blocker or have heart failure or significant left ventricular dysfunction because of drug's negative inotropic effect on some patients.

**WARNING** Expect to taper dosage gradually before discontinuing drug. Otherwise, angina or dangerously high blood pressure could result.

## PATIENT TEACHING

- Urge patient to take nicardipine as prescribed, even if she feels well.
- Instruct patient to swallow E.R. capsules whole, not to chew, crush, cut, or open them.
- Advise patient not to take drug within 1 hour of eating a high-fat meal or grapefruit product. Urge her not to alter the amount of grapefruit products in her diet without consulting prescriber.

**WARNING** Caution patient against stopping nicardipine abruptly because angina or dangerously high blood pressure could result.

- Teach patient how to take her pulse, and urge her to notify prescriber immediately if it falls below 50 beats/minute.
- Teach patient how to measure blood pressure, and urge her to do so weekly if drug was prescribed for hypertension. Suggest that she keep a log of blood pressure readings and take it to follow-up visits.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise patient to notify prescriber immediately about chest pain that's not relieved by rest or nitroglycerin, constipation, irregular heartbeats,

nausea, pronounced dizziness, severe or persistent headache, and swelling of hands or feet.

- Encourage patient to comply with suggested lifestyle changes, such as alcohol moderation, low-fat or low-sodium diet, regular exercise, smoking cessation, stress management, and weight reduction.
- Inform patient that hot tubs, prolonged hot showers, or saunas may cause dizziness or fainting.
- Instruct patient to avoid prolonged sun exposure and to use sunscreen when going outdoors.

## nicotine for inhalation

**Nicotrol Inhaler**

## nicotine nasal solution

**Nicotrol NS**

## nicotine polacrilex

**Nicorette, Nicorette Plus (CAN)**

## nicotine transdermal system

**Habitrol, NicoDerm CQ, NICOTINE TRANSDERMAL SYSTEM PATCH KIT, Nicotrol, ProStep**

## Class and Category

*Pharmacologic class:* Nicotinic agonist

*Therapeutic class:* Smoking cessation adjunct

## Indications and Dosages

- *As adjunct to smoking cessation for the relief of nicotine withdrawal symptoms, including craving*

### CHEWING GUM (NICORETTE, NICORETTE PLUS)

**Adults.** *Initial:* For patient who smokes first cigarette later than 30 min after waking up, 2 mg (1 piece) or for patient who smokes first cigarette within 30 minutes of waking up, 4 mg (1 piece) every 1 to 2 hr, for 1 to 6 wk; then 2 or 4 mg every 2 to 4 hr for 7 to 9 wk; and then 2 or 4 mg every 4 to 8 hr for 10 to 12 wk. *Maximum:* 24 pieces daily for no longer than 12 wk.

### NASAL SPRAY (NICOTROL NS)

**Adults.** 1 to 2 sprays (1 to 2 mg) in each nostril/hr.  
*Maximum:* 5 mg/hr or 40 mg daily for up to 3 mo.

### LOZENGES (NICORETTE)

**Adults who smoke first cigarette more than 30 min after waking up.** 2 mg (1 lozenge) when needed using at least 9 lozenges daily for 6 wk, then daily amount decreased for remaining 6 wk.

**Adults who smoke first cigarette within 30 min after waking up.** 4 mg (1 lozenge), when needed using at least 9 lozenges daily for 6 wk, then daily amount decreased for remaining 6 wk. *Maximum:* No more than 1 lozenge at a time, no use of lozenges continuously one after another, no

more than 5 lozenges in 6 hr; no more than 20 lozenges daily. Not to be used longer than 12 wk.

## **ORAL INHALATION (NICOTROL INHALER)**

**Adults.** 6 to 16 cartridges (24 to 64 mg) daily for up to 12 wk with dosage adjustment made according to signs and symptoms of nicotine excess or withdrawal; then dosage gradually reduced over 12 wk or less. *Maximum:* 16 cartridges (64 mg) daily for 6 mo.

## **TRANSDERMAL PATCH (NICOTROL)**

**Adults who smoke more than 10 cigarettes a day.** 15-mg patch once daily for 6 wk, then 10-mg patch once daily for 2 wk, then 5-mg patch once daily for 2 wk.

**Adults who smoke 10 or less cigarettes a day.** 10-mg patch once daily for 6 wk, then 5-mg patch once daily for 2 wk.

## **TRANSDERMAL SYSTEM (HABITROL, NICODERM CQ, NICOTINE TRANSDERMAL SYSTEM PATCH KIT)**

**Adults who smoke more than 10 cigarettes a day.** 21-mg patch daily for wk 1 through 4; 14-mg patch daily for wk 5 & 6; 7-mg patch daily for wk 7 & 8.

**Adults who smoke 10 cigarettes or less a day.** 14-mg patch daily for 6 wk followed by 7-mg patch daily for two additional wk.

## **TRANSDERMAL SYSTEM (PROSTEP)**

**Adults.** *Initial:* 11 to 22 mg daily, adjusted to lower-dose systems over 6 to 12 wk.

***DOSAGE ADJUSTMENT*** For patients with moderate to severe hepatic or renal impairment, dosage may need to be reduced.

# Mechanism of Action

Binds selectively to nicotinic-cholinergic receptors at autonomic ganglia, in the adrenal medulla, at neuromuscular junctions, and in the brain. By providing a lower dose of nicotine than cigarettes, this drug reduces nicotine craving and withdrawal symptoms.

# Contraindications

Hypersensitivity to nicotine or its components, including menthol or soy

# Interactions

## DRUGS

*acetaminophen, adrenergic antagonists (labetalol, prazosin), beta blockers, imipramine, insulin, oxazepam, pentazocine, theophylline*: Possibly increased therapeutic effects of these drugs (chewing gum, nasal spray, transdermal system)

*adrenergic agonists (isoproterenol)*: Decreased effectiveness of these drugs

*tricyclic antidepressants*: Possibly altered pharmacologic actions of these drugs (oral inhalation)

## FOODS

*acidic beverages (citrus juices, coffee, soft drinks, tea, wine)*: Decreased nicotine absorption from gum if beverages consumed within 15 minutes before or while chewing gum

*caffeine*: Increased effects of caffeine (chewing gum, nasal spray, transdermal system)

# Adverse Reactions

**CNS:** Dizziness, dream disturbances, drowsiness, headache, irritability, light-headedness, nervousness (chewing gum, transdermal system); amnesia, confusion, difficulty speaking, headache, migraine headache, paresthesia (nasal spray); chills, fever, headache, paresthesia (oral inhalation)

**CV:** **Arrhythmias** (all forms); hypertension (chewing gum, transdermal system); peripheral edema (nasal spray)

**EENT:** Increased salivation, injury to teeth or dental work, mouth injury, oral blistering, pharyngitis, stomatitis (chewing gum); altered taste, dry mouth (chewing gum, transdermal system); altered smell and taste, burning eyes, dry mouth, earache, epistaxis, gum disorders, hoarseness, lacrimation, mouth and tongue swelling, nasal blisters, nasal irritation or ulceration, pharyngitis, rhinitis, sinus problems, sneezing, vision changes (nasal spray); altered taste, lacrimation, pharyngitis, rhinitis, sinusitis, stomatitis (oral inhalation)

**GI:** Eructation (chewing gum); abdominal pain, constipation, diarrhea, flatulence, increased appetite, indigestion, nausea, vomiting (chewing gum, transdermal system); abdominal pain, constipation, diarrhea, flatulence, hiccups, indigestion, nausea (nasal spray); diarrhea, flatulence, hiccups, indigestion, nausea, peptic ulcer (transdermal), vomiting (oral inhalation)

**GU:** Dysmenorrhea (chewing gum, transdermal system); menstrual irregularities (nasal spray)

**MS:** Jaw and neck pain (chewing gum); arthralgia, myalgia (chewing gum, transdermal system); arthralgia, back pain, myalgia (nasal spray); back pain (oral inhalation)

**RESP:** Cough (chewing gum, transdermal system); bronchitis, **bronchospasm**, chest tightness, cough,

dyspnea, increased sputum production (nasal spray); chest tightness, cough, dyspnea, wheezing (oral inhalation)

**SKIN:** Diaphoresis, erythema, pruritus, rash, urticaria (chewing gum, transdermal system); acne, flushing of face, pruritus, purpura, rash (nasal spray); pruritus, rash, urticaria (oral inhalation)

**Other:** **Anaphylaxis**, delayed wound healing, flu-like symptoms, generalized pain, physical dependence, **hypersensitivity reactions**, withdrawal symptoms

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug use is not recommended during pregnancy.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that drug should be used with caution in patients with hyperthyroidism, insulin-dependent diabetes, or pheochromocytoma because nicotine releases catecholamines from the adrenal medulla, which affects the drug dosing treatment of these disorders.
- Use caution when nicotine is given with patients with active gastric or peptic ulcers or who have esophagitis because nicotine delays healing in ulcer disease.
- Know that when administering nicotine by oral inhalation, expect optimal effect to result from continuous puffing for 20 minutes.

- Keep in mind to avoid possible burns, remove patch before patient has an MRI.

## **PATIENT TEACHING**

- Instruct patient to read and follow package instructions to obtain best results with nicotine product.
- Advise patient to notify prescriber about other conditions or drugs she takes.
- Emphasize that patient must stop smoking as soon as nicotine treatment starts to avoid toxicity.
- Tell patient to stop taking drug and notify prescriber or seek emergency medical care if she develops an allergic reaction such as difficulty breathing or a rash or experiences an irregular heartbeat or palpitations, or signs of nicotine overdose.
- For chewing gum therapy, instruct patient to wait at least 15 minutes after drinking coffee, juice, soft drink, tea, or wine. Advise her to chew gum until she detects a tingling sensation or peppery taste and then to place gum between her cheek and gum until tingling or peppery taste subsides. Then direct her to move gum to a different site until tingling or taste subsides, repeating until she no longer feels the sensation—usually about 30 minutes. Caution against swallowing the gum. Advise her to stop use and contact prescriber if she experiences oral blistering.
- For nasal spray, tell patient to tilt her head back and spray into a nostril. Caution against inhaling, sniffing, or swallowing spray because nicotine is absorbed through nasal and oral mucosa.
- Warn patient that prolonged use of nasal form may cause dependence.
- For oral inhalation, tell patient to use 6 to 16 cartridges daily to prevent or relieve withdrawal symptoms and craving. Starting with 1 or 2 cartridges daily yields poor success. Direct patient to inhale through device like a cigarette, puffing often for 20 minutes.
- For transdermal system, tell patient not to open package until just before use because nicotine is lost in the air. Advise her to apply system to clean, dry, hairless site on upper outer arm or upper body. Instruct her to change systems and rotate sites every 24 hours and not to use the same site for 7 days. To avoid possible burns, advise patient to remove patch before undergoing any MRI procedure.

**WARNING** Urge patient to keep all unused nicotine forms safely away from children and pets and to discard used forms carefully. (Enough nicotine may remain in used systems to poison children and pets.) Instruct her to contact a poison control center immediately if she suspects that a child has ingested nicotine.

- Explain to patient with asthma or COPD that nicotine may cause bronchospasm.
- Inform patient that it may take several attempts to stop smoking. Urge her to join a smoking cessation program.

## nifedipine

**Adalat CC, Adalat XL (CAN),  
Afeditab CR, Procardia, Procardia XL**

### Class and Category

*Pharmacologic class:* Calcium channel blocker

*Therapeutic class:* Antianginal, antihypertensive

### Indications and Dosages

➤ *To manage chronic stable angina, vasospastic angina*

#### **CAPSULES (PROCARDIA)**

**Adults.** *Initial:* 10 mg three times daily, increased over 1 to 2 wk as needed. *Maintenance:* 10 to 20 mg three times daily *Maximum:* 180 mg daily, 30 mg/dose.

## E.R. TABLETS (PROCARDIA XL)

**Adults.** *Initial:* 30 or 60 mg daily, increased over 7 to 14 days, as needed. *Maximum:* 120 mg daily.

## E.R. TABLETS (ADALAT XL)

**Adults.** *Initial:* 30 mg once daily, increased, as needed, over 7 to 14 days. *Maximum:* 90 mg daily.

➤ *To manage hypertension*

## E.R. TABLETS (ADALAT CC, AFEDITAB CR)

**Adults.** *Initial:* 30 mg daily, increased, as needed, over 7 to 14 days. *Maintenance:* 30 to 60 mg daily. *Maximum:* 90 mg daily.

## E.R. TABLETS (ADALAT XL)

**Adults.** *Initial:* 20 or 30 daily, increased over 7 to 14 days, as needed. *Maintenance:* 30 to 60 mg daily. *Maximum:* 90 mg daily.

## E.R. TABLETS (PROCARDIA XL)

**Adults.** 30 or 60 mg daily, increased over 7 to 14 days, as needed. *Maximum:* 120 mg daily.

**DOSAGE ADJUSTMENT** Dosage may be reduced for elderly patients and those with heart failure or impaired hepatic or renal function.

Route	Onset	Peak	Duration
P.O. (caps)	20 min	Unknown	Unknown

## Mechanism of Action

May slow movement of calcium into myocardial and vascular smooth-muscle cells by deforming calcium channels in cell membranes, inhibiting ion-controlled gating mechanisms, and disrupting calcium release from sarcoplasmic reticulum. Decreasing intracellular calcium level inhibits smooth-muscle cell contraction and dilates arteries, which decreases myocardial oxygen demand, peripheral resistance, blood pressure, and afterload.

## Contraindications

Hypersensitivity to nifedipine or its components

## Interactions

### DRUGS

*cimetidine, clarithromycin, erythromycin, fentanyl, fluconazole, fluoxetine, indinavir, itraconazole, nefazodone, nelfinavir, saquinavir*: Increased risk of hypotension  
*beta blockers*: Increased risk of profound hypotension, heart failure, and worsening of angina  
*digoxin*: Transiently increased blood digoxin level, increased risk of digitalis toxicity  
*oral anticoagulants*: Possibly increased prothrombin time  
*phenytoin*: Decreased systemic exposure of nifedipine  
*quinidine*: Possibly decreased plasma quinidine level

### FOODS

*grapefruit, grapefruit juice*: Possibly increased bioavailability of nifedipine

## Adverse Reactions

**CNS:** Anxiety, ataxia, confusion, dizziness, drowsiness, headache, nervousness (possibly extreme), nightmares, paresthesia, psychiatric disturbance, syncope, tremor, weakness

**CV:** **Bradycardia**, chest pain, **heart failure**, **hypotension**, palpitations, peripheral edema, tachycardia

**EENT:** Altered taste, blurred vision, dry mouth, epistaxis, gingival hyperplasia, nasal congestion, pharyngitis, sinusitis, tinnitus

**ENDO:** Gynecomastia, hyperglycemia

**GI:** Anorexia; constipation; diarrhea; dyspepsia; elevated liver enzymes; **GI bleeding**, irritation, or **obstruction**; **hepatitis**; nausea; vomiting

**GU:** Dysuria, nocturia, polyuria, sexual dysfunction, urinary frequency

**HEME:** Anemia, **leukopenia**, positive Coombs' test, **thrombocytopenia**

**MS:** Joint stiffness, muscle cramps

**RESP:** Chest congestion, cough, dyspnea, respiratory tract infection, wheezing

**SKIN:** Acute generalized exanthematous pustulosis, diaphoresis, **erythema multiforme**, **exfoliative dermatitis**, flushing, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm, according to animal studies.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding

## Nursing Considerations

- Be aware that patients with galactose intolerance should not take nifedipine because the drug contains lactose. The capsule form of nifedipine should not be used to treat hypertension because its effects on blood pressure are not known.
- Use cautiously in patients with cirrhosis because it is unknown how nifedipine exposure may be altered in these patients.
- Know that when starting and stopping nifedipine therapy, taper it, as prescribed, over 7 to 14 days.
- Keep in mind that because of drug's negative inotropic effect on some patients, frequently monitor heart rate and rhythm, as well as blood pressure, especially in patients who take a beta blocker or have heart failure, significant left ventricular dysfunction, or tight aortic stenosis.
- Monitor fluid intake/output and daily weight; fluid retention may lead to heart failure. Also assess for signs of heart failure, such as crackles, dyspnea, jugular vein distention, peripheral edema, and weight gain.

## PATIENT TEACHING

- Instruct patient to swallow E.R. tablets whole, not to break, chew, or crush them. Inform her that their empty shells may appear in stool.
- Urge patient to take nifedipine exactly as prescribed, even when she's feeling well. Advise her to notify prescriber if she misses two or more doses.
- Urge patient not to take drug within 1 hour of a high-fat meal or grapefruit. Urge her not to alter the amount of grapefruit in her diet without consulting prescriber.

**WARNING** Caution patient against stopping nifedipine abruptly because angina or dangerously high blood

pressure could result.

- Teach patient to measure blood pressure and pulse rate, and advise her to call prescriber if they drop below accepted levels. Suggest keeping a log of weekly measurements and taking it to follow-up visits.
- Instruct patient to notify prescriber immediately about chest pain, difficulty breathing, ringing in ears, and swollen gums.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcoholic beverages because they may worsen dizziness, drowsiness, and hypotension.
- Teach patient to minimize constipation by increasing her intake of fluids, if allowed, and dietary fiber.
- Emphasize the need to comply with prescribed lifestyle changes, such as alcohol moderation, low-fat or low-sodium diet, regular exercise, smoking cessation, stress reduction, and weight reduction.
- Emphasize the need for good oral hygiene and regular dental visits.
- Caution patient that hot tubs, prolonged hot showers, and saunas may cause dizziness and fainting.
- Advise patient to avoid prolonged sun exposure and to wear sunscreen outdoors.

## nitrofurantoin

**Furadantin, Macrobid, Macrochantin**

### **Class and Category**

*Pharmacologic class:* Nitrofuran

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute cystitis due to Enterococci, Escherichia coli, or Staphylococcus aureus; certain strains of Enterobacter or Klebsiella species*

### **CAPSULES, ORAL SUSPENSION**

**Adults and adolescents.** 50 to 100 mg four times daily and continued for 1 wk or at least 3 days after urine is negative for bacteria. Alternatively using Macrobid, 100 mg every 12 hr for 7 days.

### **CAPSULES, ORAL SUSPENSION (FURADANTIN)**

**Children over age 1 month.** 5 to 7 mg/kg/day in four divided doses, continued for 1 wk or at least 3 days after urine is negative for bacteria.

### **CAPSULES, ORAL SUSPENSION (MACRODANTIN)**

**Children over 3 months.** 3 mg/kg/day in four divided doses for 7 days.

- *To suppress chronic cystitis*

### **CAPSULES, ORAL SUSPENSION**

**Adults.** 50 to 100 mg at bedtime.

**Children over age 1 month.** 1 to 2 mg/kg daily at bedtime or divided into two doses and given q 12 hr.

## Mechanism of Action

Alters or inactivates bacterial ribosomal proteins and other macromolecules. This action of nitrofurantoin inhibits aerobic energy metabolism, bacterial protein synthesis, cell wall synthesis, DNA synthesis, and RNA synthesis.

Nitrofurantoin is bacteriostatic at low doses and bactericidal at higher doses.

## Contraindications

Acute porphyria (Macrobid, Macrochantin); age under 1 month (Furadantin), under 3 months (Macrochantin), or 12 years and under (Macrobid); anuria; creatinine clearance less than 60 ml/min; G6PD (Macrobid, Macrochantin); history of cholestatic jaundice or hepatic dysfunction with previous nitrofurantoin therapy; hypersensitivity to nitrofurantoin, other nitrofurans, or their components; oliguria; pregnancy near term (38 to 42 weeks)

## Interactions

### DRUGS

*antacids containing magnesium trisilicate*: Decreased nitrofurantoin absorption

*live vaccines*: Possibly diminished therapeutic effect of the vaccines

*uricosuric such as probenecid, sulfinpyrazone*: Increased nitrofurantoin serum levels with increased risk of toxicity; decreased urinary levels with decreased effectiveness

### FOODS

*all foods*: Delays gastric emptying increasing absorption

## Adverse Reactions

**CNS**: Chills, confusion, depression, headache, **neurotoxicity**, peripheral neuropathy

**CV**: Vasculitis

**EENT:** Optic neuritis, parotitis, tooth discoloration

**GI:** Abdominal pain, anorexia, cholestatic jaundice, diarrhea, **hepatic necrosis**, **hepatitis**, jaundice, nausea, **pancreatitis**, **pseudomembranous colitis**, vomiting

**GU:** Rust-colored to brown urine

**HEME:** **Aplastic anemia**, **granulocytopenia**, **hemolytic anemia**, **leukopenia**, megaloblastic anemia, **methemoglobinemia**, **thrombocytopenia**

**MS:** Arthralgia, myalgia

**RESP:** **Asthma** (in asthmatic patients), **cyanosis**, **interstitial pneumonitis**, **pulmonary fibrosis**

**SKIN:** Alopecia; eczematous, erythematous, or maculopapular eruptions; **erythema multiforme**; **exfoliative dermatitis**; pruritus; rash; **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, **angioedema**, drug-induced fever, lupus-like syndrome

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug is contraindicated when labor is imminent, during labor and delivery, and in the neonate under 1 month of age because drug may cause hemolytic anemia in the fetus and neonate.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Obtain a specimen of patient's urine for culture and sensitivity tests, as ordered; review test results if possible before giving nitrofurantoin.
- Give drug with food or milk to avoid staining teeth.
- Don't break or crush capsules.
- Shake oral nitrofurantoin suspension before pouring dose, and mix with food or milk, as needed.
- Monitor patient for evidence of superinfection, such as abdominal pain, diarrhea, and fever. If patient develops diarrhea, it may indicate pseudomembranous colitis caused by *Clostridium difficile*. Notify prescriber and expect to withhold nitrofurantoin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient for hepatic and pulmonary abnormalities because rare but severe reactions have occurred with nitrofurantoin use, especially in the elderly.
- Observe patient for changes in nervous function because peripheral neuropathy, although uncommon, may become severe or irreversible. Patients with anemia, debilitating disease, diabetes mellitus, electrolyte imbalance, renal impairment, or vitamin B deficiency are at higher risk for peripheral neuropathy.

## PATIENT TEACHING

- Instruct patient to shake nitrofurantoin oral suspension before measuring dose and to take drug with food or milk.
- Caution patient against taking any preparations that contain magnesium trisilicate during therapy.
- Explain that urine may turn brown, orange, or rust-colored during therapy.
- Instruct patient to complete prescribed course of therapy even if symptoms subside before course is completed.

- Urge patient to tell prescriber about diarrhea that's severe or lasts longer than 3 days. Explain that bloody or watery stools can occur 2 or more months after nitrofurantoin therapy and can be serious, requiring prompt treatment.

## nitroglycerin

(glyceryl trinitrate)

**GoNitro, Minitran Patch, Nitro-Bid Ointment, Nitro-Dur Patch, Nitrolingual Pumpspray, NitroMist, Nitrostat, Rectiv, Transderm-Nitro, Trinipatch (CAN)**

### Class and Category

*Pharmacologic class:* Nitrate

*Therapeutic class:* Antianginal, vasodilator

### Indications and Dosages

➤ *To prevent acute anginal attacks*

#### TRANSDERMAL OINTMENT

**Adults.** *Initial:* 1/2 inch of 2% ointment twice daily with first dose applied upon awakening and second dose 6 hr later. Dosage increased, in 1/2 inch increments and/or dosing frequency to three or four times daily, as needed.

## TRANSDERMAL PATCH

**Adults.** *Initial:* 0.2 to 0.4 mg/hr worn 12 to 14 hr, with dosage increased or decreased, as needed.

## S.L. POWDER

**Adults.** 400 mcg (1 packet) sprinkled under tongue 5 to 10 min before exertion.

- *To treat acute angina pectoris; to reduce or limit anginal attacks before exercise*

## S.L. TABLETS

**Adults.** 0.3 to 0.6 mg, repeated every 5 min for an acute attack or taken 5 to 10 min before exercise. *Maximum:* 3 tabs in 15 min.

## S.L. POWDER

**Adults.** 400 or 800 mcg (1 or 2 packets) sprinkled under tongue, repeated every 5 min, as needed for an acute attack or taken 5 to 10 min before exercise. *Maximum:* 1,200 mcg (3 packets) in 15 min.

## TRANSLINGUAL SPRAY

**Adults.** 1 or 2 metered doses (400 or 800 mcg) onto or under tongue, repeated every 5 min, as needed, for an acute attack or taken 5 to 10 min before exercise. *Maximum:* 3 sprays within 15 min.

- *To treat acute angina when oral therapy has been ineffective; to manage hypertension related to surgery or heart failure following an acute myocardial infarction to induce intraoperative hypotension*

## I.V. INFUSION

**Adults.** 5 mcg/min, increased by 5 mcg/min every 3 to 5 min to 20 mcg/min, as needed, and then by 10 to 20 mcg/min every 3 to 5 min, if higher dosage is needed.

➤ *To treat moderate to severe pain associated with chronic anal fissure*

## RECTAL OINTMENT (RECTIV)

**Adults.** 1 inch (375 mg of ointment equivalent to 1.5 mg of nitroglycerin) to intra-anal area every 12 hr for up to 3 wk.

Route	Onset	Peak	Duration
P.O.*	20-45 min	Unknown	8-12 hr
I.V.	1-2 min	Unknown	3-5 min
S.L.	1-3 min	Unknown	30-60 min
Trans-dermal <sup>†</sup>	In 30 min	Unknown	4-8 hr
Trans-dermal <sup>‡</sup>	In 30 min	Unknown	8-24 hr
Trans-lingual	2 to 4 min	Unknown	30-60 min

\* E.R.

† Ointment.

‡ Patch.

## Mechanism of Action

May interact with nitrate receptors in vascular smooth-muscle cell membranes. This interaction reduces nitroglycerin to nitric oxide, which activates the enzyme guanylate cyclase, increasing intracellular formation of cGMP. Increased cGMP level may relax vascular smooth muscle by forcing calcium out of muscle cells, causing vasodilation. Venous dilation decreases venous return to the heart, reducing left ventricular end-diastolic pressure and pulmonary artery wedge pressure. Arterial dilation decreases systemic arterial pressure, systemic vascular

resistance, and mean arterial pressure. Thus, nitroglycerin reduces preload and afterload, decreasing myocardial workload and oxygen demand. It also dilates coronary arteries, increasing blood flow to ischemic myocardial tissue and provides analgesic effects in anal tissue.

## **Incompatibilities**

Don't administer I.V. nitroglycerin through I.V. bags or tubing made of polyvinyl chloride. Don't mix drug with other solutions.

## **Contraindications**

Acute MI (S.L.), angle-closure glaucoma, cerebral hemorrhage, circulatory failure and shock, concurrent use of phosphodiesterase inhibitors (avanafil, sildenafil, tadalafil, vardenafil) or riociguat, constrictive pericarditis (I.V.), head trauma, hypersensitivity to adhesive in transdermal form, hypersensitivity to nitrates, or their components, hypotension (I.V.), hypovolemia (I.V.), inadequate cerebral circulation (I.V.), increased intracranial pressure, orthostatic hypotension, pericardial tamponade (I.V.), restrictive cardiomyopathy (I.V.), severe anemia

## **Interactions**

### **DRUGS**

*antihypertensives, beta-adrenergic blockers, calcium channel blockers:* Increased risk of additive hypotensive effects.

*aspirin:* Increased nitroglycerin concentrations enhancing vasodilatory and hemodynamic effects of nitroglycerin

*ergotamine and related drugs: Possibly precipitate angina (oral nitroglycerin)*

*heparin: Possibly decreased anticoagulant effect of heparin phosphodiesterase inhibitors (such as avanafil, sildenafil, tadalafil, vardenafil), riociguat: Possibly severe hypotensive effect of nitroglycerin*

*tissue-type plasminogen activator (t-PA): Decreases thrombolytic effect of t-PA.*

## **ACTIVITIES**

*alcohol use: Possibly increased orthostatic hypotension*

## **Adverse Reactions**

**CNS:** Agitation, anxiety, dizziness, drowsiness, headache, insomnia, restlessness, syncope, weakness

**CV:** **Arrhythmias**, edema, **hypotension**, orthostatic hypotension, palpitations, tachycardia

**EENT:** Blurred vision, burning or tingling in mouth (S.L. forms), dry mouth

**GI:** Abdominal pain, diarrhea, indigestion, nausea, vomiting

**GU:** Dysuria, impotence, urinary frequency

**HEME:** **Methemoglobinemia**

**MS:** Arthralgia

**RESP:** Bronchitis, pneumonia, transient hypoxemia

**SKIN:** Contact dermatitis (transdermal forms), **exfoliative dermatitis**, flushing of face and neck, rash

**OTHER:** **Hypersensitivity reactions**

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Know that patients receiving oral nitroglycerin should not receive ergotamine and related drugs, if possible, because oral administration of nitroglycerin significantly increases effects of ergotamine and related drugs.
- Use nitroglycerin cautiously in elderly patients, especially those who are volume-depleted or taking several medications, because of the increased risk of falls and hypotension. Hypotension may be accompanied by angina and paradoxical slowing of the heart rate. Hypotension may become severe, especially in patients in an upright position, even with small doses, particularly in patients with aortic or mitral stenosis, constrictive pericarditis, or who are already experiencing hypotension. Symptoms of severe hypotension include collapse, nausea, pallor, perspiration, syncope, vomiting, and weakness. Notify prescriber immediately if these occur, and provide appropriate treatment, as ordered.
- Use nitroglycerin cautiously in patients with hypertrophic obstructive cardiomyopathy because nitrate therapy may aggravate angina in this condition.
- Plan a nitroglycerin-free period of about 10 hours each day, as prescribed, to maintain therapeutic effects and avoid tolerance.
- Don't break or crush E.R. capsules. Have patient swallow them whole with a full glass of water.
- Place S.L. tablet under patient's tongue and make sure it dissolves completely.
- Place patient in sitting position, if possible, when administering S.L. powder. Have patient open mouth, sprinkle powder under tongue. Have patient close mouth and breathe normally. Allow powder to dissolve without patient swallowing. Do not allow patient to rinse mouth or spit for five minutes after administration.

- When applying transdermal ointment, apply correct amount on dose-measuring paper. Then place paper on hairless area of body and spread in a thin, even layer over an area at least 2 inches by 3 inches. Don't place on cuts or irritated areas. Wash hands after application. Rotate sites. Store at room temperature.
- Open transdermal patch package immediately before use. Apply patch to hairless area, and press edges to seal. Rotate sites. Store at room temperature. If patient needs cardioversion or defibrillation, remove transdermal patch before procedure.
- Don't shake translingual spray container before administering. Have patient inhale and hold her breath, and then spray drug under or on her tongue.
- Be aware that I.V. nitroglycerin should be diluted only in D<sub>5</sub>W or normal saline solution and shouldn't be mixed with other infusions. The pharmacist should add drug to a glass bottle, not a container made of polyvinyl chloride. Don't use a filter because plastic absorbs drug. Administer with infusion pump.
- Check vital signs before every dosage adjustment and often during therapy.
- Monitor frequently heart and breath sounds, level of consciousness, fluid intake and output, and pulmonary artery wedge pressure, if possible.
- Store premixed containers in the dark; don't freeze them.

**WARNING** Assess patient for evidence of overdose, such as confusion, diaphoresis, dyspnea, flushing, headache, hypotension, nausea, palpitations, tachycardia, vertigo, vision changes, and vomiting. Treat as prescribed by removing nitroglycerin source, if possible; elevating legs above heart level; and administering an alpha-adrenergic agonist, as prescribed, to treat severe hypotension.

## **PATIENT TEACHING**

- Teach patient to recognize signs and symptoms of angina pectoris, including chest fullness, pain, and pressure, possibly with sweating and nausea. Pain may radiate down left arm or into neck or jaw. Inform

women and those with diabetes mellitus or hypertension that they may feel only fatigue and shortness of breath.

- Instruct patient to read and follow package instructions to obtain full benefits of drug.
- Inform patient that prescriber may order a 10- to 12-hour drug-free period at night (or at another time if she has chest pain at night or in the morning) to prevent drug tolerance. Also inform patient that drug should be taken as prescribed as excessive use may lead to tolerance as well.
- Instruct patient to swallow E.R. capsules whole—not to break, chew, or crush them—with a full glass of water.
- For sublingual use, advise patient to place 1 or 2 packets of powder or 1 tablet under her tongue or in buccal pouch (tablet form only) when angina starts and then to sit or lie down. Instruct her not to swallow drug, but to let it dissolve. Explain that moisture in her mouth helps drug absorption. Remind patient not to rinse mouth or spit for 5 minutes after using drug. If angina doesn't subside, instruct patient to place another packet of powder or tablet under her tongue or in buccal pouch (tablet form only) after 5 minutes and to repeat, if needed, for three doses total. If pain doesn't subside after 15 minutes, urge patient to call 911 or another emergency service.
- Advise patient to carry S.L. packets of powder or tablets in their original brown bottle in a purse or jacket pocket, but not one that will be affected by body heat. Instruct her to store drug in a dry place at room temperature and to discard cotton from container. Advise her to discard and replace S.L. tablets after 6 months. Tell her to note date on packets of powder and not to use beyond the expiration date printed.
- Advise patient using transdermal ointment or patch to rotate sites to avoid skin sensitization.
- Inform patient that swimming or bathing doesn't affect transdermal forms but that electric blankets, hot tubs, magnetic therapy, prolonged hot showers, and saunas over the site may increase drug absorption and cause dizziness and hypotension.
- Caution against inhaling translingual spray. Before first use, tell patient to press actuator button 10 times to prime container and then hold container upright with forefinger on top of actuator button. Tell her to open her mouth, bring container as close as possible, press actuator button firmly to release spray onto or under tongue, and release button and immediately close her mouth. Remind her to replace plastic cover on container and to not spit out the drug or rinse her mouth for 5 to 10 minutes. Tell her to reprime container by pressing actuator button twice if container hasn't been used for more than 6 weeks. Remind patient to periodically check level of fluid in container. If it reaches the top or

middle hole on side of container, more should be obtained. Caution patient not to let level of liquid get to bottom of hole.

- Inform patient that nitroglycerin commonly causes headache, which typically resolves after a few days of continuous therapy. Suggest taking acetaminophen, as needed, and not contraindicated.
- Advise patient to notify prescriber immediately about blurred vision, dizziness, and severe headache.
- Suggest that patient change positions slowly to minimize orthostatic hypotension.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol and erectile dysfunction drugs during therapy.
- Advise patient to alert all prescribers of nitroglycerin use because of potential drug interactions.
- Advise patient to alert all prescribers of nitroglycerin use because of potential drug interactions.

## nitroprusside sodium

**Nipride (CAN), Nitropress**

### Class and Category

*Pharmacologic class:* Vasodilator

*Therapeutic class:* Antihypertensive, vasodilator

### Indications and Dosages

- *To treat hypertensive crisis and acute heart failure; to produce controlled hypotension in order to reduce bleeding during surgery*

## I.V. INFUSION

**Adults and children.** *Initial:* 0.3 mcg/kg/min, increased gradually every few minutes, as needed, until desired level is reached. *Maximum:* 10 mcg/kg/min.

**DOSAGE ADJUSTMENT** For children weighing less than 10 kg (22 lb), infusion rate may be reduced.

Route	Onset	Peak	Duration
I.V.	1-2 min	Immediate	1-10 min

## Mechanism of Action

May interact with nitrate receptors in vascular smooth-muscle cell membranes. This action reduces nitroprusside to nitric oxide and then activates intracellular guanylate cyclase, which increases the cGMP level. Increased cGMP level may relax vascular smooth muscle by forcing calcium out of muscle cells. Smooth-muscle relaxation causes arteries and veins to dilate, which reduces peripheral vascular resistance and blood pressure.

## Incompatibilities

Don't mix nitroprusside with any other drug.

## Contraindications

Acute heart failure associated with decreased peripheral vascular resistance, concomitant use of riociguat, compensatory hypertension when primary hemodynamic lesion is aortic coarctation or arteriovenous shunting, congenital optic atrophy, decreased cerebral perfusion, hypersensitivity to nitroprusside or its components, tobacco-induced amblyopia, use of PDE-5 inhibitors, used

to produce hypotension during surgery in patients with inadequate circulation or moribund patients (A.S.A. Class 5E) requiring emergency surgery

## Interactions

### DRUGS

*ganglionic blockers, inhaled anesthetics, negative inotropic agents:* Increased hypotensive effect

*PDE-5 inhibitors, riociguat:* Increased risk of hypotension

## Adverse Reactions

**CNS:** Anxiety, dizziness, headache, **increased intracranial pressure**, nervousness, restlessness

**CV:** **Hypotension**, tachycardia

**ENDO:** Hypothyroidism

**GI:** Abdominal pain, ileus, nausea, vomiting

**HEME:** **Methemoglobinemia**

**MS:** Muscle twitching

**SKIN:** Diaphoresis, flushing, rash

**Other:** Infusion-site phlebitis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Obtain baseline vital signs before administering nitroprusside.

**WARNING** Don't give drug undiluted. Reconstitute with 2 ml D<sub>5</sub>W, and add solution to 250 to 500 ml D<sub>5</sub>W to produce 200 or 100 mcg/ml, respectively.

- Be aware that solution is stable at room temperature for 24 hours when protected from light. Don't use reconstituted solution if it contains particles or is blue, green, red, or darker than faint brown.
- Use an infusion pump. Place opaque cover over infusion container because drug is metabolized by light. I.V. tubing doesn't need to be covered.
- Keep patient supine when starting drug or titrating dose up or down.
- Monitor blood pressure continuously with intra-arterial pressure monitor. Record blood pressure every 5 minutes at start of infusion and every 15 minutes thereafter.
- Be aware that if patient has severe heart failure, expect to administer an inotropic drug, such as dopamine or dobutamine, as prescribed.

**WARNING** Know that patient who receives prolonged nitroprusside therapy or short-term high-dose therapy should be watched for evidence of thiocyanate toxicity (ataxia, blurred vision, delirium, dizziness, dyspnea, headache, hyperreflexia, loss of consciousness, nausea, tinnitus, and vomiting). Toxicity can cause arrhythmias, metabolic acidosis, severe hypotension, and death.

- Monitor serum thiocyanate level at least every 72 hours; levels above 100 mcg/ml are associated with toxicity.

**WARNING** Assess patient for evidence of cyanide toxicity (absence of reflexes, coma, distant heart sounds, hypotension, metabolic acidosis, mydriasis, pink skin, shallow respirations, and weak pulse). If **detected**, discontinue nitroprusside, as ordered, and give 4 to 6 mg/kg sodium nitrite over 2 to 4 minutes to convert hemoglobin to methemoglobin. Follow with 150 to 200 mg/kg sodium thiosulfate. Repeat this regimen at half the original doses after 2 hours, as ordered.

## PATIENT TEACHING

- Advise patient to change position slowly to minimize dizziness from sudden, severe hypotension.

## norepinephrine bitartrate (levarterenol bitartrate)

**Levophed**

## Class and Category

*Pharmacologic class:* Sympathomimetic

*Therapeutic class:* Vasopressor

## Indications and Dosages

- *To manage blood pressure in acute hypotensive states such as blood transfusion, drug adverse effect, myocardial infarction, pheochromocytectomy,*

*poliomyelitis, spinal anesthesia, and sympathectomy reactions; adjunct in treatment of cardiac arrest and profound hypotension*

## **I.V. INFUSION**

**Adults.** *Initial average dose:* 8 to 12 mcg/min of base. Then titrated to maintain systolic blood pressure between 80 to 100 mm Hg in patients previously not hypertensive and 40 mm Hg below preexisting systolic blood pressure in patients previously hypertensive. *Maintenance:* 2 to 4 mcg/min of base. *Initial high dose:* Highly individualized but may require enormous daily doses as high as 68 mg of base if patient remains hypotensive.

Route	Onset	Peak	Duration
I.V.	Rapid	Unknown	1-2 min

## **Mechanism of Action**

At more than 4 mcg/min, inhibits adenylyl cyclase and directly stimulates alpha-adrenergic receptors, which inhibits cAMP production. Inhibition of cAMP constricts arteries and veins and increases peripheral vascular resistance and systolic blood pressure.

## **Contraindications**

Concurrent use of cyclopropane and hydrocarbon inhalation anesthetics, hypersensitivity to norepinephrine or its components, hypovolemia (except as an emergency measure), mesenteric or peripheral vascular thrombosis (except as an emergency measure), profound hypercarbia or hypoxia

# Interactions

## DRUGS

*cyclopropane and halothane anesthetics:* Increased cardiac autonomic irritability, sensitizing the myocardium to the action of norepinephrine

*MAO inhibitors of the imipramine or triptyline types:* May cause prolonged, severe hypertension

## Adverse Reactions

**CNS:** Anxiety, dizziness, headache, insomnia, nervousness, tremor, weakness

**CV:** Angina, **bradycardia**, **ECG changes**, edema, hypertension, **hypotension**, palpitations, peripheral vascular insufficiency (including gangrene), **PVCs**, sinus tachycardia

**GI:** Nausea, vomiting

**GU:** Decreased renal perfusion

**RESP:** Apnea, dyspnea

**SKIN:** Pallor

**Other:** Infusion-site sloughing and tissue necrosis, **metabolic acidosis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Dilute norepinephrine concentrate for infusion by adding a 4 ml ampule (contains 4 mg) of drug to 1,000 ml of a 5% dextrose-containing solution. Each ml of this dilution contains 4 mcg of the base of the drug.
- Make sure solution contains no particles and isn't discolored before administering.
- Give drug with a flow-control device.
- Check blood pressure every 2 to 3 minutes, preferably by direct intra-arterial monitoring, until stabilized and then every 5 minutes.

**WARNING** Because extravasation can cause severe tissue damage and necrosis, expect prescriber to give multiple subcutaneous injections of phentolamine (5 to 10 mg diluted in 10 to 15 ml normal saline solution) around extravasated infusion site.

- If blanching occurs along vein, change infusion site and notify prescriber at once.
- Monitor continuous ECG during therapy.

## PATIENT TEACHING

- Urge patient to immediately report burning, leaking, or tingling around I.V. site.

**nortriptyline hydrochloride**

**Aventyl (CAN), Pamelor**

---

## Class and Category

*Pharmacologic class:* Tricyclic antidepressant (TCA)

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat depression*

### CAPSULES, ORAL SOLUTION

**Adults.** *Initial:* 25 mg three times a day or four times a day. Alternatively, total daily dose once daily. *Maximum:* 150 mg daily.

**Adolescents and the elderly.** 30 to 50 mg daily in divided doses. Alternatively, total daily dose once daily.

Route	Onset	Peak	Duration
P.O.	2–3 wk	Unknown	Unknown

## Mechanism of Action

May interfere with reuptake of serotonin (and possibly other neurotransmitters) at presynaptic neurons, thus enhancing serotonin's effects at postsynaptic receptors. By restoring normal neurotransmitter levels at nerve synapses, this tricyclic antidepressant may elevate mood.

## Contraindications

Acute recovery phase of MI; hypersensitivity to nortriptyline, other dibenzazepines, tricyclic antidepressants, or their components; use within 14 days of

MAO inhibitor therapy including intravenous methylene blue or linezolid

## Interactions

### DRUGS

*barbiturates, CNS depressants*: Possibly increased CNS depression

*chlorpropamide*: Possibly significant hypoglycemia

*cimetidine*: Increased plasma concentrations of nortriptyline

*MAO inhibitors (including I.V. methylene blue, linezolid), serotonergic drugs (buspirone, fentanyl, lithium, St. John's Wort, tramadol, tricyclic antidepressants, triptans, tryptophan)*: Increased risk of serotonin syndrome

*P4502D6 inhibitors such as cimetidine, fluoxetine and other antidepressants, phenothiazines, quinidine, selective serotonin reuptake inhibitors type IC antiarrhythmics (flecainide, propafenone)*: Possibly increased plasma concentration of these drugs with possible increase in adverse reactions

*other anticholinergics, sympathomimetic drugs*: Increased risk of profound hypertension

*reserpine*: Possibly produce a stimulating effect

### ACTIVITIES

*alcohol use*: Increased alcohol effects, CNS and respiratory depression, hypertension

## Adverse Reactions

**CNS**: Ataxia, confusion, **CVA**, delirium, dizziness, drowsiness, excitation, hallucinations, headache, insomnia,

nervousness, nightmares, Parkinsonism, **serotonin syndrome, suicidal ideation**, tremor

**CV: Arrhythmias**, orthostatic hypotension, **unmasking of Brugada syndrome**

**EENT:** Angle-closure glaucoma, blurred vision, dry mouth, increased intraocular pressure, taste perversion

**GI:** Constipation, diarrhea, heartburn, ileus, increased appetite, nausea, vomiting

**GU:** Sexual dysfunction, urine retention

**HEME: Bone marrow depression**

**RESP:** Wheezing

**SKIN:** Diaphoresis, urticaria

**Other:** Weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect to stop MAO inhibitor therapy, including intravenous methylene blue and linezolid, 10 to 14 days before starting nortriptyline.
- Know that nortriptyline should be avoided in patients with Brugada syndrome or those suspected of having the disorder because Brugada

syndrome can cause abnormal ECG findings and syncope as well as increasing the risk of sudden death.

- Watch patient closely (especially adolescents and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Be aware that oral solution (10 mg/5 ml) is 4% alcohol.

**WARNING** Monitor patient for possible serotonin syndrome, characterized by agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. Notify prescriber immediately if serotonin syndrome is suspected because it can become life-threatening and expect to discontinue nortriptyline therapy.

- Give nortriptyline with food to reduce GI reactions.
- Monitor blood nortriptyline level; therapeutic range is 50 to 150 ng/ml.
- Monitor ECG tracing to detect arrhythmias.

## **PATIENT TEACHING**

- Explain that oral solution contains alcohol.
- Discourage alcohol consumption during therapy.
- Explain that improvement may take weeks.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a teenager or young adult.

- Instruct patient to change position slowly to minimize orthostatic hypotension.
- Encourage patient to inform prescriber if there is a family history of sudden unexplained death before the age of 45 before nortriptyline is begun or if abnormal heartbeat or unexplained fainting occurs during nortriptyline therapy.
- Suggest that patient minimize constipation by drinking plenty of fluids (if allowed), exercising regularly, and eating high-fiber foods.

## nystatin

### Class and Category

*Pharmacologic class:* Polyene macrolide

*Therapeutic class:* Antifungal

### Indications and Dosages

➤ *To treat oral candidiasis (thrush)*

#### ORAL SUSPENSION

**Adults and children.** 400,000 to 600,000 units (4 to 6 ml) swished and swallowed four times a day until at least 48 hr after symptoms subside.

**Infants.** 200,000 units (2 ml) applied to each side of mouth four times a day until at least 48 hr after symptoms subside.

➤ *To treat intestinal candidiasis*

#### TABLETS

**Adults.** 500,000 to 1,000,000 units (1 to 2 tablets) every 8 hr.

\*Topical use found in Appendix.

## **Mechanism of Action**

Binds to sterols in fungal cell membranes, impairing membrane integrity. Cells lose intracellular potassium and other cellular contents and, eventually, die.

## **Contraindications**

Hypersensitivity to nystatin or its components

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**ENDO:** Hyperglycemia (oral suspension)

**GI:** Abdominal pain, diarrhea, nausea, vomiting (oral forms)

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Prepare nystatin powder for oral suspension for each dose; it has no preservatives.

## PATIENT TEACHING

- Tell patient to swish oral suspension in her mouth as long as possible before swallowing.
- Review adverse reactions with patient and to report them to prescriber if prolonged or severe.

**obiltoxaimab**

**Anthim**

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antianthrax agent

## Indications and Dosages

- *To prevent inhalational anthrax due to Bacillus anthracis when alternative therapies are not*

*appropriate or available; to treat inhalational anthrax due to *B. anthracis* in combination with appropriate antibacterial drugs*

## **I.V. INFUSION**

**Adults and children weighing more than 40 kg (88 lb).** 16 mg/kg over 90 min as a single dose.

**Adults and children weighing more than 15 kg (33 lb) to 40 kg (88 lb):** 24 mg/kg over 90 min as a single dose.

**Children weighing 15 kg (33 lb) or less.** 32 mg/kg over 90 min as a single dose.

## **Mechanism of Action**

Binds to the PA component of the *B. anthracis* toxin to inactivate it.

## **Contraindications**

Hypersensitivity to obiltoxaximab or its components

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**CNS:** Dizziness, dysphonia, fatigue, fever, headache

**CV:** Chest discomfort or pain, palpitations

**EENT:** Dry mouth, nasal congestion, oropharyngeal pain, rhinorrhea, sinus congestion

**GI:** Vomiting

**HEME:** leukopenia, lymphopenia, neutropenia

**MS:** Extremity pain, myalgia, musculoskeletal pain

**RESP:** Cough, cyanosis, dyspnea, upper respiratory infections

**SKIN:** Pruritus, urticaria

**Other:** Anaphylaxis; antibody formation against obiltoximab; increased creatine phosphokinase; infusion-site reactions of bruising, discoloration, pain, swelling, or urticaria

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that obiltoximab should only be used for prophylaxis when its benefit for prevention of inhalational anthrax outweighs the risk of anaphylaxis and other hypersensitivity reactions.
- Be aware that because obiltoximab does not have antibacterial activity, it must be used in combination with appropriate antibacterial drugs.
- Expect to premedicate patient with diphenhydramine because drug can cause serious hypersensitivity reactions including anaphylaxis.
- Do not shake drug vial. Know that there are two ways to prepare and dilute the drug for infusion. To prepare and dilute drug in infusion bag,

first calculate the required dosage and volume according to manufacturer guidelines. Know that each single vial allows delivery of 6 ml of obiltoxaximab. Select an appropriate size bag of 0.9% sodium chloride injection, USP. Withdraw a volume of solution from the bag equal to the calculated volume in milliliters of the drug to be administered and discard. Then withdraw the required volume of the drug from the drug vial(s) and discard any unused portion remaining in the vial(s). Transfer the required volume of the drug into the selected infusion bag. Gently invert the bag to mix the solution. Do not shake. Know that the prepared solution is stable for 8 hours stored in the refrigerator or at room temperature. To prepare and dilute the drug using the syringe for infusion method, first calculate the required dosage and volume of the drug according to manufacturer guidelines. Select an appropriate size syringe for the total volume of infusion to be administered. Using the selected syringe, withdraw the required volume of drug. Discard any unused portion remaining in the vial(s). Withdraw an appropriate amount of 0.9% sodium chloride injection, USP, using the syringe containing the drug to prepare the total infusion volume specified in manufacturer guidelines. Gently mix the solution. Do not shake. Once diluted in the syringe, administer immediately. Do not store solution in syringe.

- Administer drug intravenously as an infusion using either of the stated methods of dilution. Use a 0.22-micron inline filter and infuse at the rate specified in the manufacturer guidelines in order for the drug to be administered over 90 minutes. Flush the intravenous line with 0.9% sodium chloride injection, USP, at the end of the intravenous infusion.

**WARNING** Be aware that because of the risk for serious hypersensitivity reactions, including anaphylaxis, the drug should be administered in an environment conducive to treating anaphylaxis. Monitor patient closely for signs and symptoms of hypersensitivity that may progress rapidly to anaphylaxis. Know that hypersensitivity reactions were the most common adverse reactions that occurred in the safety trials for obiltoxaximab. Observe the patient throughout the infusion and for a period of time after administration. Stop infusion immediately if hypersensitivity or anaphylaxis occurs, notify prescriber and provide supportive care, as ordered.

## **PATIENT TEACHING**

- Inform patient of the possibility of an allergic reaction that could become severe with ocrelizumab administration. Reassure him that he will be given a drug to help prevent this before ocrelizumab is given. Review the signs and symptoms of an allergic reaction with the patient and stress importance of alerting the healthcare staff administering the drug if any should occur. Tell him that if he experiences any reactions after going home, he should seek immediate medical attention.
- Tell patient that he will only need to receive the drug one time.

## ocrelizumab

### Ocrevus

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antimultiple sclerotic

## Indications and Dosages

- *To treat primary progressive multiple sclerosis; to treat relapsing forms of multiple sclerosis, including active secondary progressive disease, clinically isolated syndrome, or relapsing-remitting disease*

### I.V. INFUSION

**Adults.** *Initial:* 300 mg, followed 2 wk later by a second 300-mg infusion. Initial two doses infused starting at 30 ml per hour, then increased by 30 ml per hour every 30 min to maximum infusion rate of 180 ml per hour with an infusion duration of 2.5 hours or longer. *Maintenance:* Single infusion of 600 mg every 6 months. Maintenance dose

infused starting at 40 ml per hour, increased by 40 ml per hour every 30 min with maximum infusion of 200 ml per hour and duration of infusion 3.5 hours or longer.

Route	Onset	Peak	Duration
I.V.	Unknown	14 days	Unknown

## Mechanism of Action

Although precise mechanism is unknown, ocrelizumab binds to CD20, a cell surface antigen on pre-B and mature B lymphocytes, which results in antibody-dependent cellular cytotoxicity and complement-mediated lysis to help relieve symptoms of multiple sclerosis.

## Incompatibilities

Don't dilute ocrelizumab in any solution other than 0.9% sodium chloride injection, and use a dedicated line to infuse ocrelizumab because potential reactions are unknown if other drugs are infused through the same line.

## Contraindications

Active hepatitis B virus infection, hypersensitivity to ocrelizumab or its components

## Interactions

### DRUGS

*other immune-modulating or immunosuppressants:*

Increased risk of immunosuppression

*vaccines (live or live-attenuated):* Possibly decreased effectiveness or increased risk of infection

# Adverse Reactions

**CNS:** Depression, dizziness, fatigue, fever, headache

**CV:** **Hypotension**, peripheral edema, tachycardia

**EENT:** **Laryngeal or pharyngeal edema**, oropharyngeal pain, throat irritation

**GI:** Diarrhea, nausea

**HEME:** **Neutropenia**

**MS:** Back or extremity pain

**RESP:** **Bronchospasms**, cough, dyspnea, respiratory infections

**SKIN:** Erythema, flushing, pruritus, rash, skin infections, urticaria

**Other:** Antiocrelizumab antibody formation, decreased immunoglobulins, herpes virus-associated infections, infusion reactions

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However as a humanized monoclonal antibody it may cross the placental barrier. This may increase the potential for transient peripheral B-cell depletion and lymphocytopenia in the neonate.
- The safety and effectiveness of vaccine administration in these infants are unknown.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk. This makes B-cell depletion in the breast fed infant unknown.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- *Instruct women of childbearing age to use effective contraception during drug therapy and for 6 months after the last drug dose.*

## Nursing Considerations

- Expect to perform hepatitis B virus (HBV) screening, as ordered, prior to initiating ocrelizumab therapy because drug is contraindicated in patients with active HBV that has been confirmed by positive test results.
- Administer all necessary immunizations, as ordered, according to guidelines at least 4 weeks prior to initiation of ocrelizumab therapy for live or live-attenuated vaccines and, whenever possible, at least 2 weeks before initiation of ocrelizumab therapy for nonlive vaccines. This is because the drug may interfere with effectiveness of nonlive vaccines and safety of immunization with live or live-attenuated vaccines following ocrelizumab therapy is unknown.
- Assess patient for evidence of an active infection prior to every infusion of ocrelizumab. If present, know that the infusion must be delayed until the infection is resolved.
- Expect to premedicate the patient with 100 mg of methylprednisolone (or an equivalent corticosteroid) intravenously about 30 minutes before each ocrelizumab infusion to reduce the frequency and severity of infusion reactions. Also expect to premedicate the patient with an antihistamine such as diphenhydramine about 30 to 60 minutes prior to each ocrelizumab infusion to further reduce infusion reactions. Know that the administration of an antipyretic such as acetaminophen may also be ordered.
- Do not shake drug vial. Withdraw prescribed dose and further dilute into an infusion bag containing 0.9% sodium chloride injection to a final drug concentration of approximately 1.2 mg/ml. For example, withdraw 10 mg (300 mg) from vial and inject into a 250-ml infusion bag containing 0.9% sodium chloride injection solution or withdraw 20 ml (600 mg) from vial and inject into a 500-ml infusion bag containing 0.9% sodium chloride injection solution. Do not use any other diluents to dilute ocrelizumab.
- Know that prepared infusion solution should be at room temperature prior to starting the intravenous infusion. Administer the prepared infusion immediately. However, know that the prepared solution can be stored for up to 24 hours in the refrigerator or 8 hours at room temperature, which includes the infusion time.

- Administer the diluted ocrelizumab solution through a dedicated line using an infusion set with a 0.2 or 0.22 micron in-line filter.
- Monitor patient for infusion reactions for at least 1 hour after completion of the infusion.
- Expect to administer a planned infusion that is missed as soon as possible. Know that it should not be withheld until the next scheduled dose. Reset the dose schedule to administer the next sequential dose 6 months after the missed dose is administered, because doses must be separated by at least 5 months.

**WARNING** Monitor patient for life-threatening infusion reactions. If present, stop infusion immediately, provide supportive care, as ordered, and know that drug will be permanently discontinued. If infusion reaction is not life-threatening but severe, expect to immediately interrupt the infusion and provide supportive treatment, as ordered and needed. Expect to restart the infusion only after all symptoms have resolved. When restarting, expect to restart at half the infusion rate at the time of onset of the infusion reaction. If this rate is tolerated, increase the rate per the standard protocol. If patient is experiencing a mild to moderate infusion reaction, expect to reduce the infusion rate to half the rate at the onset of the infusion reaction and maintain the reduced rate for at least 30 minutes. If this rate is tolerated, expect to increase the rate per the standard protocol.

**WARNING** Know that progressive multifocal leukoencephalopathy (PML) has occurred in patients treated with other anti-CD20 antibodies and other multiple sclerosis therapies. Patients at risk included patients who were immunocompromised or received polytherapy with immunosuppressants. Monitor patient for PML, which may include changes in memory, orientation, or thinking that could lead to confusion and personality changes. Other symptoms include clumsiness of limbs, disturbance of vision, and

progressive weakness on one side of the body. If present, notify prescriber immediately, because PML usually leads to death or severe disability.

## PATIENT TEACHING

- Explain the importance of as well as the risks associated with ocrelizumab therapy.
- Tell patient she will receive medication before the infusion to lessen or prevent infusion reactions. However, inform patient that infusion reactions may occur up to 24 hours after the infusion and include allergic types of signs and symptoms. If adverse reactions occur in this time frame, patient should notify prescriber and if reactions are severe, seek immediate emergency medical care.
- Instruct patient to report changes in memory, orientation, or thinking that could lead to confusion and personality changes. Other symptoms to report include clumsiness of limbs, disturbance of vision, and progressive weakness on one side of the body. If present, urge patient to notify prescriber immediately.
- Inform patient that live or live-attenuated vaccines should not be given within 4 weeks of starting drug therapy and for 2 weeks prior to starting drug therapy for nonlive vaccines. Also tell mothers of infants exposed to drug during pregnancy to inform pediatrician of exposure before any live or live-attenuated vaccines are administered to the infant.
- Inform patient that ocrelizumab may increase risk of breast cancer. Stress importance of following standard breast cancer screening guidelines.

## ofloxacin

### Class and Category

*Pharmacologic class:* Fluoroquinolone

*Therapeutic class:* Antibiotic

# Indications and Dosages

- *To treat acute, uncomplicated cystitis caused by Escherichia coli or Klebsiella pneumoniae*

## **TABLETS**

**Adults.** 200 mg every 12 hr for 3 days.

- *To treat uncomplicated cystitis caused by Citrobacter diversus, Enterobacter aerogenes, Proteus mirabilis, or Pseudomonas aeruginosa*

## **TABLETS**

**Adults.** 200 mg every 12 hr for 7 days.

- *To treat complicated UTI caused by C. diversus, E. coli, K. pneumoniae, P. mirabilis, or P. aeruginosa*

**Adults.** 200 mg every 12 hr for 10 days.

- *To treat pelvic inflammatory disease caused by susceptible organisms only if standard cephalosporin therapy is not feasible and community prevalence of quinolone-resistant gonococcal organisms is low*

## **TABLETS**

**Adults.** 400 mg every 12 hr with metronidazole P.O. for 10 to 14 days.

- *To treat prostatitis caused by E. coli*

## **TABLETS**

**Adults.** 300 mg every 12 hr for 6 wk.

- *To treat acute exacerbation of chronic bronchitis or community-acquired pneumonia caused by Haemophilus influenzae or Streptococcus pneumoniae and uncomplicated skin and soft-tissue infections*

*caused by Proteus mirabilis, Staphylococcus aureus or Streptococcus pyogenes*

## **TABLETS**

**Adults.** 400 mg every 12 hr for 10 to 14 days.

***DOSAGE ADJUSTMENT*** If creatinine clearance is 20 to 50 ml/min, dosing interval possibly reduced to every 24 hr; if clearance is less than 10 ml/min, dosage possibly reduced by 50% and given every 24 hr. For patients with severe liver dysfunction, maximum dose limited to 400 mg daily.

## **Mechanism of Action**

Inhibits synthesis of the bacterial enzyme DNA gyrase by counteracting excessive supercoiling of DNA during replication or transcription. Inhibition of DNA gyrase causes rapid- and slow-growing bacterial cells to die.

## **Contraindications**

Hypersensitivity to ofloxacin, other fluoroquinolones, or their components

## **Interactions**

### **DRUGS**

*aluminum-, calcium-, or magnesium-containing antacids; didanosine; ferrous sulfate; magnesium-containing laxatives; multivitamins; sevelamer; sucralfate; zinc:*  
Decreased absorption of ofloxacin  
*insulin, oral antidiabetic drugs:* Possibly disturbance in blood glucose control with these agents

*NSAIDs*: Possibly increased risk of CNS stimulation and seizures

*theophylline*: Increased risk of theophylline-related adverse reactions

*procainamide*: Decreased renal clearance of procainamide

*warfarin*: Possibly increased anticoagulant activity and risk of bleeding

## Adverse Reactions

**CNS**: Aggressiveness, agitation, ataxia, **CVA**, delirium, disorientation, disturbance in attention, dizziness, drowsiness, emotional lability, exacerbation of extrapyramidal disorders and myasthenia gravis, fever, headache, incoordination, insomnia, light-headedness, mania, memory impairment, nervousness, peripheral neuropathy, psychotic reactions, restlessness, **suicidal ideation**, syncope

**CV**: **Arrhythmias**, **prolonged QT interval**, **severe hypotension**, **torsades de pointes**, vasculitis

**EENT**: Blurred vision; diplopia; disturbances in equilibrium, hearing, smell, and taste

**ENDO**: Hyperglycemia, **hypoglycemia**

**GI**: Abdominal cramps or pain, **acute hepatic necrosis or failure**, diarrhea, **hepatitis**, jaundice, nausea, **pseudomembranous colitis**, vomiting

**GU**: **Acute renal insufficiency or failure**, interstitial nephritis, renal calculi, vaginal candidiasis

**HEME**: **Agranulocytosis**, **aplastic or hemolytic anemia**, **leukopenia**, **pancytopenia**, **thrombocytopenia**

**MS**: Arthralgia; myalgia; **rhabdomyolysis**; tendinitis; tendon inflammation, pain, or rupture

**RESP**: **Hypersensitivity pneumonitis**, **pulmonary edema**

**SKIN:** Blisters, diaphoresis, erythema, **erythema multiforme, exfoliative dermatitis**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria  
**Other:** **Acidosis, anaphylaxis**, infusion-site phlebitis, serum sickness

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that because of increased risk of prolonged QT interval, ofloxacin shouldn't be used if patient has had a prolonged QT interval, has an uncorrected electrolyte disorder, or takes a Class IA or III antiarrhythmic. Monitor elderly patients closely because risk of prolonged QT interval may be increased in this group.
- Monitor patient closely for hypersensitivity, which may occur as early as first dose. Reaction may include angioedema, bronchospasm, dyspnea, itching, jaundice, rash, shortness of breath, and urticaria. If these signs or symptoms appear, notify prescriber immediately and expect to discontinue drug.
- Know that fluoroquinolones like ofloxacin have caused disabling and potentially irreversible serious adverse reactions from different body systems that can occur together in the same patient. These reactions can

occur within hours to weeks after starting the drug and usually cause central nervous system effects, peripheral neuropathy, tendinitis and tendon rupture. All ages of patients and patients without any preexisting risk factors have experienced these reactions. Notify prescriber and expect to discontinue ofloxacin immediately at the first signs or symptoms of any serious adverse reactions.

- Notify prescriber if patient has symptoms of peripheral neuropathy (burning, numbness, pain, tingling, weakness, or altered sensations of light touch, pain, position sense, temperature, or vibration sense), which could be permanent; tendon rupture (inflammation and pain), which may occur more often in patients (especially elderly ones) taking corticosteroids and requires immediate rest; or a severe photosensitivity reaction. In each case, expect to stop ofloxacin.
- Maintain adequate hydration to prevent development of highly concentrated urine and crystalluria.
- Expect an increased risk of toxicity in severe hepatic disease, including cirrhosis.
- Be aware that ofloxacin may stimulate the CNS and aggravate seizure disorders. Also know that the drug may cause many psychiatric adverse reactions. Monitor patient closely.
- If diarrhea develops, notify prescriber because it may indicate pseudomembranous colitis. Ofloxacin may have to be discontinued and additional therapy started.
- Be alert for secondary fungal infection.
- Monitor patient closely for hypoglycemia, especially if patient is elderly, has diabetes or renal insufficiency, or is taking hypoglycemic drugs such as sulfonylureas. Hypoglycemia can become severe and result in coma. Treat hypoglycemia quickly and effectively. Notify prescriber of incident and expect that drug may be replaced with a different antibiotic for this patient.

## **PATIENT TEACHING**

- Encourage patient to take each dose with a full glass of water.
- Tell patient to complete full course of ofloxacin therapy exactly as prescribed, even if he feels better before it's complete.
- Urge patient not to take antacids, iron or zinc preparations, or other drugs (such as didanosine and sucralfate), within 2 hours of ofloxacin to prevent decreased or delayed drug absorption.

- Advise patient to avoid hazardous activities until CNS effects of drug are known.
- Tell patient to limit exposure to sun and ultraviolet light to prevent phototoxicity.
- Advise patient to notify prescriber immediately about abnormal motor or sensory function, burning skin, hives, itching, rapid heart rate, rash, and tendon pain. Also advise patient to stop taking ofloxacin immediately and notify prescriber if any other persistent, serious, or worsening adverse effects occur.
- Urge patient to seek medical care immediately for trouble breathing or swallowing, which may signal an allergic reaction.
- Instruct diabetic patient who takes an antidiabetic agent or insulin to notify prescriber immediately if he develops a hypoglycemic reaction.
- Advise patient to notify prescriber if diarrhea develops, even up to 2 months after ofloxacin therapy ends. Additional therapy may be needed.

## olanzapine

**Zyprexa, Zyprex Zydis**

**olanzapine pamoate  
monohydrate**

**Zyprexa Relprevv**

## Class and Category

*Pharmacologic class:* Thienobenzodiazepine derivative

*Therapeutic class:* Antipsychotic

# Indications and Dosages

➤ *To treat schizophrenia*

## ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 5 to 10 mg daily. Once 10 mg daily dosage reached, additional dosage adjustment made in 5 mg increments every wk, as needed. *Maintenance:* 10 mg daily. *Maximum:* 20 mg daily.

**Adolescents age 13 and over.** *Initial:* 2.5 to 5 mg daily. *Maintenance:* 10 mg daily. *Maximum:* 20 mg daily.

## I.M. INJECTION-ER (ZYPREXA RELPREVV)

**Adults who have been taking 10 mg daily orally.** *Initial:* 210 mg every 2 wk for first 8 wk, then decreased to 150 mg every 2 wk. Alternatively, 405 mg every 4 wk for first 8 wk, then decreased to 300 mg every 4 wk.

**Adults who have been taking 15 mg daily orally.** *Initial:* 300 mg every 2 wk for 8 wk, then decreased to 210 mg every 2 wk or 405 mg every 4 wk.

**Adults who have been taking 20 mg daily orally.** 300 mg every 2 wk.

➤ *To treat manic phase of bipolar I disorder (manic or mixed episodes)*

## ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 10 to 15 mg daily decreased or increased in 5 mg increments every 24 hr, as needed. *Maintenance:* 5 to 20 mg daily. *Maximum:* 20 mg daily.

**Adolescents age 13 and over.** *Initial:* 2.5 to 5 mg daily, increased, as needed, in 2.5 or 5 mg increments weekly. *Maintenance:* 10 mg daily. *Maximum:* 20 mg daily.

- *As adjunct to lithium or valproate therapy to treat bipolar I disorder*

## ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.** *Initial:* 10 mg daily with lithium or valproate sodium, increased or decreased by 5 mg every 24 hr, as needed. *Maintenance:* 5 to 20 mg/day. *Maximum:* 20 mg daily.

- *To treat agitation associated with schizophrenia and bipolar I mania*

## I.M. INJECTION

**Adults.** 5 to 10 mg, as needed. Repeat as needed every 2 to 4 hr for total of 3 doses. *Maximum:* Three doses of 10 mg administered with second dose given after 2 hr and third dose given 2 hr after second dose providing patient is not exhibiting orthostatic hypotension.

***DOSAGE ADJUSTMENT*** For short-acting oral form, initial dosage possibly reduced to 5 mg for debilitated patients, those prone to hypotension, and female nonsmokers over age 65. For short-acting I.M. form, dosage decreased to 5 mg for elderly patients and 2.5 mg for debilitated patients, female nonsmokers over age 65, and those prone to hypotension. For extended-release I.M. form, dosage decreased to 150 mg every 4 weeks for patients who are debilitated, female nonsmokers over 65, or those prone to hypotension.

Route	Onset	Peak	Duration
P.O., I.M.-E.R.	1 wk	Unknown	Unknown
I.M.	Unknown	Unknown	Unknown

## Mechanism of Action

May achieve antipsychotic effects by antagonizing dopamine and serotonin receptors. Anticholinergic effects may result from competitive binding to and antagonism of the muscarinic receptors M<sub>1</sub> through M<sub>5</sub>.

## Contraindications

Hypersensitivity to olanzapine or its components

## Interactions

### DRUGS

*antihypertensives*: Increased effects of antihypertensives, increased risk of hypotension

*carbamazepine, rifampin*: Increased olanzapine clearance

*CNS depressants*: Additive CNS depression, potentiated orthostatic hypotension

*diazepam*: Potentiated orthostatic hypotension

*dopamine agonists, levodopa*: Antagonized effects of these drugs

*fluoxetine, fluvoxamine*: Decreased olanzapine clearance

*lorazepam (parenteral)*: Possibly increased somnolence with I.M. olanzapine injection

### ACTIVITIES

*alcohol use*: Potentiated orthostatic hypotension

*smoking*: Decreased blood olanzapine level

## Adverse Reactions

**CNS**: Abnormal gait, agitation, akathisia, altered thermoregulation, amnesia, anxiety, asthenia, dizziness, euphoria, fatigue, fever, headache, hypertonia, insomnia,

motor and sensory instability, nervousness, **neuroleptic malignant syndrome**, restless leg syndrome, restlessness, somnolence, stuttering, **suicidal ideation**, syncope, tardive dyskinesia, thirst, tremor

**CV:** **Bradycardia**, chest pain, elevated triglyceride levels, hyperlipidemia, hypertension, **hypotension**, orthostatic hypotension, peripheral edema, tachycardia, **venous thromboembolic events**

**EENT:** Amblyopia, dry mouth, increased salivation, pharyngitis, rhinitis

**ENDO:** **Diabetic coma**, **diabetic ketoacidosis**, hyperglycemia, **hyperprolactinemia**

**GI:** Abdominal pain, **cholestatic** or **mixed liver injury**, constipation, dysphagia, elevated liver enzymes, **hepatitis**, increased appetite, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Priapism, urinary incontinence, UTI

**HEME:** **Agranulocytosis**, **leukopenia**, **neutropenia**

**MS:** Arthralgia; back, joint, or limb pain; muscle spasms and twitching; **rhabdomyolysis**

**RESP:** Cough, **pulmonary embolism**

**SKIN:** **Ecchymosis**, photosensitivity, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, discontinuation reaction, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms, injection site abscess, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.

- Drug may cause fetal harm as exposure to drug during the third trimester of pregnancy increases the risk for extrapyramidal and/or withdrawal symptoms following delivery.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding. However, if breastfeeding occurs, infant should be monitored for excess sedation, extrapyramidal symptoms, poor feeding, and irritability.

## REPRODUCTION

- Drug may cause an increase in serum prolactin levels, which may lead to a reversible reduction in fertility in females of childbearing age.

## Nursing Considerations

**WARNING** Olanzapine shouldn't be used for elderly patients with dementia-related psychosis because drug increases risk of death in these patients.

- Use cautiously in patients with hepatic impairment or conditions associated with limited hepatic functional reserve and in patients who are being treated with potentially hepatotoxic drugs. Also use cautiously in patients with known cardiovascular or cerebrovascular disease and conditions that would predispose patient to hypotension, such as presence of dehydration, hypovolemia, or treatment with antihypertensive medications because of the increased risk for bradycardia, hypotension, and syncope.

**WARNING** Keep in mind that there are two formulations for I.M. injection. One is an immediate release formulation and one is an extended release. They are not interchangeable. When administering drug

intramuscularly, make sure the right formulation is being administered.

- Reconstitute parenteral immediate-release olanzapine by dissolving contents of vial in 2.1 ml sterile water to yield 5 mg/ml. Solution should be clear yellow. Use within 1 hour.
- Inject I.M. immediate-release olanzapine slowly, deep into muscle mass.
- Reconstitute parenteral extended-release olanzapine using only the diluent provided as follows: for 150 or 210 mg dose, use 1.3 ml of diluent; for 300 mg dose, use 1.8 ml of diluent; and for 405 mg dose, use 2.3 ml diluent. Withdraw predetermined diluent into syringe. Inject into powder vial and withdraw air to equalize pressure. Remove needle and hold vial upright. Pad a hard surface, then tap vial firmly and repeatedly on the surface until no powder is visible. Shake vial vigorously until suspension appears smooth and consistent in color and texture (yellow and opaque). If foam has formed, let vial stand until it has dissipated. Administer immediately or if stored for up to 24 hr, remember drug vial must be vigorously shaken to resuspend solution prior to administration. Attach new needle to syringe and slowly withdraw desired amount into the syringe. Remove needle from syringe.
- Administer parenteral extended-release olanzapine by first attaching a 19 gauge needle or larger to syringe to prevent clogging. Inject intramuscularly deeply into the gluteal muscle. Withdraw needle. Do not massage injection site.
- Keep patient recumbent after I.M. injection of olanzapine if drowsiness, dizziness, bradycardia, or hypoventilation occurs. Don't let patient sit or stand up until blood pressure and heart rate have returned to baseline.
- Be aware that following the injection of extended-release olanzapine, patient may experience a syndrome similar to an olanzapine overdose, with delirium and sedation being the primary symptoms. Know that patient must be observed for 3 hours following each injection for this syndrome. Notify prescriber immediately if it should occur.
- Monitor patient's blood pressure routinely during therapy because olanzapine may cause orthostatic hypotension.
- Be aware that olanzapine may worsen such conditions as angle-closure glaucoma, benign prostatic hyperplasia, and seizures. Monitor patient closely.
- Assess daily weight to detect fluid retention or metabolic changes.
- Notify prescriber if patient develops tardive dyskinesia or urinary incontinence.

- Be alert for and immediately report signs of neuroleptic malignant syndrome.
- Watch patient closely (especially adolescent and young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Monitor patient's lipid levels throughout therapy, as ordered, because olanzapine may cause significant elevations.
- Monitor patient's blood glucose level routinely because olanzapine may increase risk of hyperglycemia.
- Monitor CBC often during first few months of therapy, especially if patient has low WBC count or history of drug-induced leukopenia or neutropenia. If WBC count declines, and especially if neutrophil count drops below  $1,000/\text{mm}^3$ , expect olanzapine to be discontinued. If neutropenia is significant, also monitor patient for fever or other evidence of infection and provide appropriate treatment, as prescribed.
- Be aware that drug may cause hyperprolactinemia, which, in turn, may reduce pituitary gonadotropin secretion. This then inhibits reproductive function by impairing gonadal steroidogenesis in both female and male patients. In addition, longstanding hyperprolactinemia may decrease bone density in patient when it is associated with hypogonadism.
- Know that olanzapine may cause a drug reaction with eosinophilia and systemic symptoms called DRESS. Although uncommon, it can become fatal. Assess patient regularly for a cutaneous reaction exhibited by eosinophilia, exfoliative dermatitis, fever, lymphadenopathy, or rash. Know that systemic complications such as hepatitis, myocarditis and/or pericarditis, nephritis, or pneumonitis also may occur. If suspected, stop olanzapine and notify prescriber immediately. Expect to provide supportive care, as ordered.
- Institute fall precautions, especially in patients with conditions, diseases, or concurrent drug therapy that could exacerbate effects of motor and sensory instability, postural hypotension, and somnolence.

## **PATIENT TEACHING**

- Advise patient to avoid alcohol and smoking during olanzapine therapy.
- Teach patient to open orally disintegrating tablet sachet by peeling back foil on the blister, not by pushing tablet through the foil. Immediately after opening blister, tell him to use dry hands to remove tablet and place

it in his mouth. Explain that tablet will disintegrate rapidly in saliva so he can easily swallow it without liquid.

- Caution patient with phenylketonuria that disintegrating olanzapine tablets contain phenylalanine.
- Tell patient receiving the extended-release parenteral form of olanzapine, that she will need to be monitored for at least 3 hours following the injection. Stress importance of reporting any unusual symptoms including altered thoughts and lethargy immediately to healthcare professional.
- Urge patient to avoid hazardous activities until drug's CNS effects are known. Also inform patient of increased risk for falls because of potential CNS effects. Review fall precautions with patient.
- Instruct patient to change position slowly to minimize effects of orthostatic hypotension.
- Encourage patient to weigh self frequently to detect weight gain. If diabetes is present, also instruct patient to monitor blood glucose level closely.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a teenager or young adult.
- Warn patient that chronic olanzapine therapy may alter reproductive function through olanzapine-induced hyperprolactinemia causing amenorrhea and impotence. If reproductive adverse effects occur, patient should notify prescriber.
- Instruct patient to notify prescriber of any persistent, severe, or worsening adverse reactions, including fever, rash, or swollen glands or change in body function.

## olmesartan medoxomil

### Benicar

## Class and Category

*Pharmacologic class:* Angiotensin II receptor blocker (ARB)

*Therapeutic class: Antihypertensive*

## Indications and Dosages

➤ *To manage or as adjunct to manage hypertension*

### Mechanism of Action

Olmesartan medoxomil blocks angiotensin II from binding to receptor sites in many tissues, including adrenal glands and vascular smooth muscle.

Angiotensin II, a potent vasoconstrictor, is then free to stimulate the adrenal cortex to secrete aldosterone, and the inhibiting effects of angiotensin II reduce blood pressure.

Description

## SUSPENSION, TABLETS

**Adults, adolescents, and children age 6 and over who weigh 35 kg (77 lb) or more.** *Initial:* 20 mg daily, increased in 2 wk to 40 mg daily, as needed. *Maximum:* 40 mg daily.

**Adolescents and children age 6 and over who weigh 20 kg to less than 35 kg (44 to 77 lb).** *Initial:* 10 mg daily, increased in 2 wk to 20 mg daily, as needed. *Maximum:* 20 mg daily.

**DOSAGE ADJUSTMENT** Lower starting dosage is recommended for patients with possible depletion of intravascular volume, such as those treated with diuretics, especially if impaired renal function is present.

## Contraindications

Aliskiren therapy in patients with diabetes or renal impairment (GFR less than 60 ml/min), hypersensitivity to olmesartan medoxomil or its components

## Interactions

### DRUGS

*ACE inhibitors, aliskiren (in patients with diabetes or renal impairment), other angiotensin receptor blockers:*

Increased risk of hyperkalemia, hypotension, and renal dysfunction

*colesevelam:* Reduced effectiveness of olmesartan  
*drugs that may increase potassium levels such as heparin, potassium-sparing diuretics, potassium supplements:*

Increased risk of hyperkalemia

*lithium:* Increased serum lithium level with possible toxicity

*NSAIDs:* Increased risk of renal dysfunction in elderly patients and patients who are volume-depleted or have preexisting renal dysfunction; increased antihypertensive effect of olmesartan

## **FOOD**

*salt substitutes containing potassium:* Increased risk of hyperkalemia

## **Adverse Reactions**

**CNS:** Asthenia, dizziness, fatigue, headache, insomnia, vertigo

**CV:** Chest pain, hypercholesterolemia, hyperlipidemia, hypertriglyceridemia, peripheral edema, tachycardia

**EENT:** Pharyngitis, rhinitis, sinusitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, diarrhea, gastroenteritis, indigestion, nausea, sprue-like enteropathy, vomiting

**GU:** **Acute renal failure**, elevated BUN and serum creatinine levels, hematuria, UTI

**MS:** Arthralgia, arthritis, back pain, myalgia, **rhabdomyolysis**, skeletal pain

**RESP:** Bronchitis, cough, upper respiratory tract infection

**SKIN:** Alopecia, pruritus, rash, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia**, hyperuricemia, increased CK level, flu-like symptoms, pain

## **Childbearing Considerations**

### **PREGNANCY**

- Drug causes fetal harm.

- Drug given during the second or third trimester reduces fetal renal function and increases fetal and neonatal morbidity and death. Resulting oligohydramnios can cause fetal lung hypoplasia and skeletal malformations.
- Drug should be discontinued as soon as pregnancy is known.

## **LACTATION**

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Be aware that olmesartan should not be given to children under the age of one because the drug can have adverse effects on the development of immature kidneys.
- Expect to provide treatment such as normal saline solution I.V., as prescribed, to correct known or suspected hypovolemia before beginning olmesartan therapy.
- Make 200 ml of a 2-mg/ml suspension for children or adults who cannot swallow tablets by adding 50 ml of purified water to an amber polyethylene terephthalate (PET) bottle containing twenty 20-mg tablets and allow to stand for a minimum of 5 minutes. Shake the container for at least 1 minute and allow the suspension to stand for at least 1 minute. Repeat 1-minute shaking and 1-minute standing for four additional times. Add 100 ml of Ora-Sweet and 50 ml of Ora-Plus to the suspension and shake well for at least 1 minute. Refrigerate the suspension for up to 4 weeks. Shake the suspension well before each use and return promptly to the refrigerator.
- Monitor patient for increased BUN and serum creatinine levels, especially in a patient with impaired renal function, because drug may cause acute renal failure. If increased levels are significant or persist, notify prescriber immediately.
- Monitor blood pressure frequently to assess effectiveness of therapy. If blood pressure isn't controlled with olmesartan alone, expect to administer a diuretic, such as hydrochlorothiazide, as prescribed but know that diuretics or other antihypertensive drugs during olmesartan therapy increases the risk of hypotension.

- Expect to discontinue drug temporarily if patient experiences hypotension. Place patient in supine position immediately and prepare to administer normal saline solution I.V., as prescribed. Expect to resume drug therapy after blood pressure stabilizes.
- Know that if patient also receives a diuretic, adequate hydration should be provided, as appropriate, to help prevent hypovolemia. Watch for evidence of hypovolemia, such as hypotension with dizziness and fainting.
- Monitor patient's electrolytes regularly, as ordered, and observe patient for signs and symptoms of electrolyte imbalances, especially hyperkalemia, because drug inhibits the renin-angiotensin system and may cause hyperkalemia. Risks for hyperkalemia include concomitant use of potassium-sparing diuretics, potassium supplements and/or potassium containing salt substitutes; and patients with diabetes mellitus or renal insufficiency.
- Monitor patient for chronic severe diarrhea and substantial weight loss as drug may cause these symptoms even months to years after drug initiation.

## **PATIENT TEACHING**

- Teach patient, parent, or caregiver how to mix olmesartan suspension if patient is unable to swallow tablets.
- Advise patient to avoid exercise in hot weather and excessive alcohol use to reduce the risk of dehydration and hypotension. Also instruct him to notify prescriber if he has prolonged diarrhea, nausea, or vomiting.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Explain the importance of proper diet, regular exercise, and other lifestyle changes in controlling hypertension.
- Advise female patient to notify prescriber immediately about known or suspected pregnancy. Explain that if she becomes pregnant, prescriber will need to replace olmesartan with another antihypertensive that's safe to use during pregnancy.

**olodaterol**

# Striverdi Respimat

## Class and Category

*Pharmacologic class:* Long-acting beta2-adrenergic agonist

*Therapeutic class:* Bronchodilator

## Indications and Dosages

- *To treat long-term airflow obstruction in patients with chronic obstructive pulmonary disease (COPD), including chronic bronchitis and/or emphysema*

## ORAL INHALATION

**Adults.** 5 mcg (2 inhalations) once daily at same time each day.

## Mechanism of Action

By binding and activating beta2-adrenoceptors in the airways, intracellular adenylyl cyclase (an enzyme that mediates the synthesis of cyclic-3' 5'-adenosine monophosphate [cAMP]) is stimulated. Elevated levels of cAMP cause bronchodilation by relaxing airway smooth muscle cells.

## Contraindications

Asthma without use of a long-term asthma control drug, hypersensitivity to olodaterol or its components

## Interactions

## DRUGS

*adrenergic agents*: Potentiated sympathetic effects

*beta blockers*: Decreased effectiveness of olodaterol and beta blockers; possibly severe bronchospasm

*diuretics, steroids, xanthine derivatives*: Increased risk of hypokalemia

*drugs known to prolong QT interval, MAO inhibitors, tricyclic antidepressants*: Possibly adverse cardiovascular effects

*ketoconazole*: Possibly increased serum olodaterol level

*non-potassium-sparing diuretics*: Possibly increased risk of ECG changes and hypokalemia

## Adverse Reactions

**CNS**: Dizziness, fever

**CV**: **Atrial fibrillation**, chest pain, **ECG changes**, palpitations, tachycardia

**EENT**: Nasopharyngitis

**ENDO**: Hyperglycemia

**GI**: Constipation, diarrhea

**GU**: UTI

**MS**: Arthralgia, back pain

**RESP**: Bronchitis, COPD exacerbation, cough, **paradoxical bronchospasms**, pneumonia, upper respiratory infection

**SKIN**: Rash

**Other**: **Anaphylaxis**, **angioedema**, **hypokalemia**, **immediate hypersensitivity reactions**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Drug may inhibit labor due to a relaxant effect on uterine smooth muscle.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Know that olodaterol therapy should not be used in patients with acutely deteriorating COPD, which may be a life-threatening condition. It should also not be used for relief of acute episodes of bronchospasm.
- Use caution when administering olodaterol to patients with cardiovascular disorders, such as arrhythmias, coronary insufficiency, hypertension, or hypertrophic obstructive cardiomyopathy; to patients with seizure disorders or thyrotoxicosis; and to patients who are unusually responsive to sympathomimetic amines or are at risk for developing prolonged QT interval.
- Administer olodaterol only by oral inhalation. Remember to prime inhaler before using for the first time.
- Watch patient closely for paradoxical bronchospasm. If present, discontinue olodaterol therapy immediately, notify prescriber, and implement treatment according to standard of care.

**WARNING** Monitor patient for worsening or deteriorating asthma because asthma-related deaths have increased in patients receiving salmeterol, a drug in the same class as olodaterol. Be aware that use of long-acting beta2-adrenergic agonists such as olodaterol is contraindicated in patients with asthma without the use

of a long-term asthma control medication, such as an inhaled corticosteroid. Monitor patient closely and notify prescriber immediately of any changes in patient's respiratory status.

- Monitor patients with a history of cardiovascular disorders. Notify prescriber of any significant increases in blood pressure or pulse rate or worsening of chronic conditions. Olodaterol may also cause ECG changes such as flattening of the T wave, prolonged QT interval, and ST-segment depression. Drug may need to be discontinued if such reactions occur.

**WARNING** Watch patient closely for hypersensitivity reactions. If present, stop olodaterol therapy immediately, notify prescriber, and provide emergency treatment according to standard of care.

- Monitor patient's serum potassium level and assess for signs and symptoms of hypokalemia, especially if patient has severe COPD, because hypokalemia may be made worse by hypoxia and concomitant treatment.

## **PATIENT TEACHING**

- Advise patient, especially if she has a significant cardiac history, to inform prescriber of any other drugs she is taking before beginning olodaterol therapy and to keep prescriber informed of any new drug therapies while taking olodaterol.
- Caution patient not to increase olodaterol dosage or frequency without consulting prescriber because serious adverse reactions may occur.
- Instruct patient on how to load the cartridge into the inhaler. Remind patient that after insertion, the unit must be primed before first use by actuating the inhaler toward the ground until an aerosol cloud is visible and then repeating the process three more times. If not used for more than 3 days, remind patient to actuate the inhaler once before use; if not used for more than 21 days, tell patient to prime inhaler as if using for the first time.
- Teach patient how to use inhaler. Stress importance of using inhalation spray only with the Striverdi Respimat inhaler and that the inhaler should not be used for administering other drugs.

**WARNING** Caution patient that immediate hypersensitivity reactions, including swelling of face or throat, may occur after administration of olodaterol. If present, patient should stop taking drug, seek immediate medical treatment, and notify prescriber.

- Urge patient to notify prescriber if her symptoms worsen, if olodaterol becomes less effective, or if she needs more inhalations of her prescribed short-acting beta2-agonist than usual. This may indicate that her condition is worsening.
- Instruct patient to notify prescriber immediately if she experiences chest pain, palpitations, rapid heart rate, or other troublesome effects while taking olodaterol because dosage may have to be adjusted.
- Tell patient that olodaterol may cause paradoxical bronchospasms. If present, tell patient to discontinue drug and notify prescriber. If severe or unrelieved, stress importance of seeking emergency treatment to relieve bronchospasms.

## olsalazine sodium

### Dipentum

## Class and Category

*Pharmacologic class:* Salicylate

*Therapeutic class:* Anti-inflammatory

## Indications and Dosages

- *To maintain remission of ulcerative colitis in patients who are intolerant of sulfasalazine*

## CAPSULES

**Adults and adolescents.** 500 mg twice daily.

## Mechanism of Action

Exerts anti-inflammatory action in GI tract after being converted by colonic bacteria to mesalamine (5-aminosalicylic acid), which inhibits cyclooxygenase. Inhibition of cyclooxygenase reduces prostaglandin production in intestinal mucosa. This in turn reduces production of arachidonic acid metabolites, which may be increased in patients with inflammatory bowel disease. Olsalazine also exerts an anti-inflammatory effect by indirectly inhibiting leukotriene synthesis, which normally catalyzes production of arachidonic acid.

## Contraindications

Hypersensitivity to olsalazine, other salicylates, or their components

## Interactions

### DRUGS

*6-mercaptopurine, thioguanine:* Increased risk of myelosuppression

*low-molecular-weight heparins or heparinoids:* Increased risk of bleeding after neuraxial anesthesia

*oral anticoagulants:* Possibly prolonged PT

*varicella vaccine:* Increased risk of Reye's syndrome

## Adverse Reactions

**CNS:** Anxiety, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, lethargy, paresthesia,

peripheral neuropathy, vertigo

**CV:** Cardiac arrest, hypotension, myocarditis, pericarditis, prolonged QT interval, second-degree AV block

**ENDO:** Hot flashes

**EENT:** Dry eyes and mouth, lacrimation, laryngeal edema, stridor, stomatitis, tinnitus

**GI:** Abdominal pain, anorexia, cholestatic jaundice, cirrhosis, diarrhea, dyspepsia, elevated liver enzymes, hepatic failure or necrosis, hepatitis, hepatotoxicity, nausea, vomiting

**GU:** Dysuria, hematuria, interstitial nephritis, nephrotic syndrome, urinary frequency

**HEME:** Aplastic or hemolytic anemia, lymphopenia, neutropenia, pancytopenia

**MS:** Arthralgia, joint pain, muscle spasms, myalgia

**RESP:** Bronchospasms, dyspnea, interstitial lung disease, shortness of breath

**SKIN:** Acne, alopecia, erythema nodosum, flushing, photosensitivity, pruritus, rash

**Other:** Anaphylaxis, angioedema, dehydration

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.

- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## Nursing Considerations

- Assess patient for aspirin allergy before giving olsalazine.
- Know that if patient has severe allergies or asthma, he should be watched closely for worsening symptoms during olsalazine therapy; notify prescriber immediately if they occur.
- Assess consistency and quantity of stools and frequency of bowel movements before, during, and after therapy.
- Give drug with food to decrease adverse GI reactions.
- Monitor skin for adequate hydration.
- Assess patient for abdominal pain and hyperactive bowel sounds.
- Monitor hepatic and renal status in patient with underlying hepatic or renal dysfunction because drug may further impair these functions.

## PATIENT TEACHING

- Instruct patient to take olsalazine with food.
- Urge patient to continue taking drug as prescribed, even if symptoms improve.
- Advise patient to watch for signs of dehydration.
- Tell patient to report unusual, persistent, or severe adverse effects to prescriber.

**omadacycline**

**Nuzyra**

# Class and Category

*Pharmacologic class:* Aminomethylcycline of the tetracycline class

*Therapeutic class:* Antibacterial

## Indications and Dosages

- *To treat community-acquired bacterial pneumonia caused by Chlamydophila pneumoniae, Haemophilus influenzae, H. parainfluenzae, Klebsiella pneumoniae, Legionella pneumophila, Mycoplasma pneumoniae, Staphylococcus aureus (methicillin-susceptible isolates), or Streptococcus pneumoniae*

### I.V. INFUSION, TABLETS

**Adults.** *Loading:* 200 mg I.V. infused over 60 min on day 1. Alternatively, 100 mg I.V. infused over 30 min twice on day 1. *Maintenance:* 100 mg I.V. infused over 30 min once daily for 7 to 14 days. Alternatively, 300 mg P.O. once daily for 7 to 14 days.

- *To treat acute bacterial skin structure and skin infections caused by Enterobacter cloacae, Enterococcus faecalis, K. pneumoniae, S. aureus (methicillin-susceptible and-resistant isolates), S. lugdunensis, S. anginosus group, or S. pyogenes*

### I.V. INFUSION, TABLETS

**Adults.** *Loading:* 200 mg I.V. infused over 60 min on day 1. Alternatively, 100 mg I.V. infused over 30 min twice on day 1 or 450 mg P.O. once daily on day 1 and day 2. *Maintenance:* 100 mg I.V. infused over 30 min once daily for 7 to 14 days if loading dose was 200 mg administered

I.V. once on day 1. Alternatively, 300 mg P.O. once daily for 7 to 14 days if loading dose was 100 mg administered I.V. twice on day 1 or 450 mg P.O. once on day 1 and day 2.

## **Mechanism of Action**

Binds to the 30S ribosomal subunit and blocks protein synthesis, exerting a bacteriostatic effect as well as a bactericidal effect against some isolates of *S. pneumoniae* and *H. influenzae*.

## **Incompatibilities**

Do not administer omadacycline intravenously with any solution containing multivalent cations such as calcium and magnesium through the same intravenous line.

## **Contraindications**

Hypersensitivity to omadacycline, other tetracycline-class antibacterial drugs or their components

## **Interactions**

### **DRUGS**

*antacids containing aluminum, calcium, or magnesium; bismuth subsalicylate; iron preparations:* Decreased absorption of oral omadacycline  
*anticoagulant drugs:* Depressed plasma prothrombin activity

### **FOODS**

*all foods, especially dairy products:* Decreased absorption of oral omadacycline

## Adverse Reactions

**CNS:** Fatigue, headache, insomnia, lethargy, vertigo

**CV:** **Atrial fibrillation**, hypertension, tachycardia

**EENT:** Oral candidiasis, oropharyngeal pain, taste distortion

**GI:** Abdominal pain, **Clostridium difficile-associated diarrhea (CDAD)**, constipation, diarrhea, dyspepsia, elevated bilirubin and liver enzymes, elevated lipase levels, nausea, vomiting

**GU:** Vulvovaginal mycotic infection

**HEME:** Anemia, thrombocytosis

**MS:** Elevated creatinine phosphokinase

**SKIN:** Excessive diaphoresis, erythema, pruritus, urticaria

**Other:** Elevated alkaline phosphatase, **hypersensitivity reactions**, infusion-site reactions (erythema, induration, inflammation, irritation, pain, swelling)

## Childbearing Considerations

### PREGNANCY

- Drug causes fetal harm such as adverse effects on skeleton growth and tooth development when given during the second and third trimester.
- The use of drug during last half of pregnancy may cause permanent discoloration of the child's teeth.
- Drug should not be used during pregnancy unless there is no alternative and benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy and for 4 days following the last dose.

## **REPRODUCTION**

- Patients should use effective contraception during drug therapy.
- Drug may reduce ovulation and increased embryonic loss in female patients according to animal studies.
- Drug may cause injury to the testis and reduced motility and reduced sperm counts in male patients according to animal studies.

## **Nursing Considerations**

- Know that omadacycline must be reconstituted and then further diluted prior to administration. Reconstitute each 100-mg vial with 5 ml of sterile water for injection. Gently swirl contents and let vial stand until the cake has completely dissolved and any foam disperses. Do not shake vial. If needed, invert vial to dissolve any remaining powder and swirl gently, to prevent foaming. Reconstituted solution should be yellow to dark orange in color; if not, discard solution.
- Dilute further immediately (within 1 hour) by withdrawing reconstituted solution from vial and adding it to a 100 ml or more of 0.9% sodium chloride injection, USP, or 5% Dextrose Injection USP intravenous bag. Concentration of the final diluted infusion solution will be either 1 mg/ml or 2 mg/ml depending on number of vials reconstituted. Use within 24 hours if diluted drug is left at room temperature or within 48 hours if refrigerated. If refrigerated, remove infusion bag from refrigerator and place in a vertical position at room temperature 60 minutes before use.
- Administer total infusion over 60 minutes for a 200-mg dose or a total infusion time of 30 minutes for a 100-mg dose. Infuse through a dedicated line or through a Y-site. If the same intravenous line is used for sequential infusion of several drugs, flush with 0.9% sodium chloride injection, USP, or 5% Dextrose Injection, USP, before and after infusion of omadacycline.
- Administer oral tablets of omadacycline with water after patient has fasted for at least 4 hours. After administration, patient should not drink (except water) or eat for 2 hours and not ingest any antacids, dairy products, iron preparations, or multivitamins for 4 hours after administration.

**WARNING** Be aware that patients treated for community-acquired bacterial pneumonia with omadacycline may have a higher risk of death, especially patients over the age of 65 and patients with multiple disorders. Monitor patients with pneumonia closely for worsening and/or complications of infection and underlying conditions.

- Know that omadacycline, as a tetracycline, may cause permanent discoloration of the teeth, enamel hypoplasia, and inhibition of bone growth in the neonate if administered during the last half of pregnancy.

**WARNING** Monitor patient for hypersensitivity reactions, because other tetracyclines have caused reactions, including anaphylaxis. If patient develops a reaction, notify prescriber and expect drug to be discontinued. Provide supportive care, as ordered and required.

- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold omadacycline and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient for tetracycline-class effects such as abnormal liver function tests, acidosis, azotemia, hyperphosphatemia, increased BUN, pancreatitis, photosensitivity, and pseudotumor cerebri. Expect omadacycline to be discontinued if any of these adverse reactions occurs.

## **PATIENT TEACHING**

- Instruct patient taking oral tablets of omadacycline to take drug with water after patient has fasted for at least 4 hours. After administration, patient should not drink (except water) or eat for 2 hours. Also tell patient not to ingest any antacids, dairy products, iron preparations, or multivitamins for 4 hours after administration.
- Inform patient that nausea and vomiting may occur with omadacycline use, especially if patient received the oral loading dose for treatment of acute bacterial skin and skin structure infections.

- Alert women who are pregnant that omadacycline may cause tooth discoloration and enamel hypoplasia later in life and inhibition of bone growth in the unborn child if the mother is exposed to omadacycline during the second or third trimester of her pregnancy.
- Alert patient that diarrhea is a common problem with antibacterial drugs. Tell patient that bloody or watery stools can occur even after omadacycline therapy has been discontinued. Stress importance of reporting diarrhea to prescriber.

**WARNING** Instruct patient to stop taking drug and seek medical attention if an allergic reaction occurs.

- Advise mothers not to breastfeed their infant during omadacycline therapy and for 4 days after the last dose of drug.

# omalizumab

## Xolair

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Antiallergenic, antiasthmatic

## Indications and Dosages

- *To treat moderate to severe persistent asthma in patients with positive skin test or in vitro reactivity to a perennial aeroallergen and symptoms have been inadequately controlled with inhaled corticosteroids*

## SUBCUTANEOUS INJECTION

**Adults and adolescents age 6 and over.** 75 to 375 mg every 2 or 4 wk. Dose and frequency determined by body weight and blood IgE levels.

***DOSAGE ADJUSTMENT*** Dosage adjusted for significant changes in body weight.

- *To treat chronic idiopathic urticaria in patients who remain symptomatic despite H1 antihistamine treatment*

## **SUBCUTANEOUS INJECTION**

**Adults and adolescents age 12 and over.** 150 or 300 mg every 4 wk.

## **Mechanism of Action**

Helps reduce inflammation by binding to circulating IgE and keeping it from binding to mast cells. This action inhibits degranulation and blocks release of histamine and other chemical mediators. In asthma, inflammation results when antigen reexposure causes mast cells to degranulate and release histamine and chemical mediators. By blocking these responses, asthma symptoms and urticaria are less likely to develop.

## **Contraindications**

Hypersensitivity to omalizumab or its components

## **Interactions**

### **DRUGS**

None reported

# Adverse Reactions

**CNS:** Dizziness, fatigue, fever, headache, vertigo

**EENT:** Earache, epistaxis, nasopharyngitis, otitis media, pharyngitis, sinusitis

**GI:** Gastroenteritis, nausea, upper abdominal pain

**HEME:** Eosinophilic conditions, **thrombocytopenia (severe)**

**MS:** Arm or leg pain, arthralgia, fractures

**RESP:** Bronchitis, cough, upper respiratory tract infection

**SKIN:** Alopecia, dermatitis, pruritus, rash, urticaria

**Other:** **Anaphylaxis**; antibodies to omalizumab; generalized pain; injection-site bruising, burning, hive or mass formation, induration, inflammation, itching, pain, redness, stinging, and warmth; lymphadenopathy; **malignancies**

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm but drug crosses the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Record patient's weight, and obtain blood IgE levels, as ordered, before starting omalizumab prescribed to treat asthma; dosage and dosing frequency are based on these factors.
- Reconstitute using sterile water for injection, and allow 15 to 20 minutes (on average) for lyophilized product to dissolve. Draw 1.4 ml sterile water for injection into a 3-ml syringe with a 1-in 18G needle. Place omalizumab vial upright, and inject sterile water into vial using aseptic technique. Gently swirl upright vial for about 1 minute to evenly wet powder. Don't shake. Every 5 minutes, gently swirl for 5 to 10 seconds until solution contains no gel-like particles. Discard if powder takes longer than 40 minutes to dissolve, and start with a new vial. Once reconstituted, solution should be clear or slightly opalescent and may have a few small bubbles or foam around edge of vial. Use omalizumab within 8 hours if refrigerated or 4 hours if stored at room temperature.
- Remove reconstituted omalizumab from vial by inverting vial for 15 seconds to let solution drain toward stopper. Using a new 3-ml syringe with a 1-in 18G needle, insert needle into inverted vial and position needle tip at the very bottom of solution in the vial stopper. Then pull plunger all the way back to end of syringe barrel to remove all solution from inverted vial. To obtain full 150-mg dose (1 vial containing 1.2 ml of reconstituted omalizumab), all product must be withdrawn from vial before expelling any air or excess solution from syringe.
- Be aware that omalizumab is also available as a prefilled syringe. However, know that the needle cover on the prefilled syringe contains dry natural rubber, which is a derivative of latex and may cause allergic reactions in individuals sensitive to latex.
- Don't give more than 150 mg of omalizumab per injection site.
- Be prepared to inject omalizumab over 5 to 10 seconds because solution is slightly viscous.

**WARNING** Monitor patient closely for hypersensitivity reactions, particularly for first 2 hours after administration. Although rare, anaphylaxis has occurred as early as first dose and more than 1 year after starting regular treatment. Keep emergency medication and equipment readily available.

**WARNING** Monitor patient closely for signs of cancer. Report any abnormal findings to prescriber.

## **PATIENT TEACHING**

- Instruct patient to notify prescriber immediately about possible hypersensitivity, such as difficulty breathing, hives, or rash.
- Caution patient that any improvement in his condition may take time.
- Encourage patient to comply with regularly scheduled prescriber visits.
- Inform patient of risk of malignancy and suggest routine cancer screening.
- Explain that omalizumab prescribed for the treatment of asthma isn't used to treat acute bronchospasm or status asthmaticus.
- Tell patient not to abruptly stop any prescribed systemic or inhaled corticosteroid when starting omalizumab therapy for asthma treatment because steroid dosage must be tapered gradually under prescriber's supervision.
- If female patient becomes pregnant within 8 weeks before or during omalizumab therapy, urge her to enroll in the Xolair Pregnancy Exposure Registry at 1-866-496-5247. Also, tell her to notify prescriber because drug may need to be changed.

## omega-3-acid ethyl esters

### Lovaza

## Class and Category

*Pharmacologic class:* Ethyl esters

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *As adjunct to diet to reduce severe triglyceride level that is equal to or exceeds 500 mg/dl*

### CAPSULES

**Adults.** 4 g once daily or 2 g twice daily.

## Mechanism of Action

Omega-3-acid ethyl esters are essential fatty acids that may inhibit very-low-density lipoprotein and triglyceride synthesis in the liver. With less triglyceride synthesis, plasma triglyceride levels decrease.

## Contraindications

Hypersensitivity to omega-3-acid ethyl esters or their components

## Interactions

### DRUGS

*anticoagulants, antiplatelets:* Possibly increased bleeding time

## Adverse Reactions

**CV:** Angina pectoris

**EENT:** Halitosis, nosebleeds, taste perversion

**GI:** Diarrhea, dyspepsia, eructation, nausea, vomiting

**HEME:** **Prolonged bleeding time, hemorrhagic diathesis**

**MS:** Back pain

**SKIN:** Bruising, rash, urticaria

**Other:** **Anaphylaxis**, flu-like symptoms

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Be aware that drugs known to increase triglyceride levels—such as beta blockers, thiazide diuretics, and estrogens—should be discontinued or changed, if possible, before omega-3 ethyl ester therapy starts.
- Expect to check patient's triglyceride level before starting and periodically throughout omega-3-acid ethyl ester therapy to determine effectiveness.
- Administer drug with meals.
- Expect to stop omega-3-acid ethyl ester therapy after 2 months if patient's triglyceride level doesn't decrease as expected.
- Monitor patient with history of paroxysmal or persistent atrial fibrillation for recurrences of symptomatic atrial fibrillation or flutter, especially within the first 2 to 3 months of initiating omega-3 ethyl ester therapy.

## **PATIENT TEACHING**

- Explain to patient the importance of dietary measures, an exercise program, and controlling other factors—such as blood glucose level—that may contribute to elevated triglyceride levels.
- Advise patient to take drug with meals.
- Explain that patient will need periodic laboratory tests to evaluate therapy.

- Instruct patient to seek immediate medical attention if an allergic reaction or chest pain occurs.

## omega 3-carboxylic acids

### Epanova

## Class and Category

*Pharmacologic class:* Fish oil derivative

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *To reduce triglyceride levels in patients with severe (equal to or greater than 500 mg/dl) hypertriglyceridemia*

## CAPSULES

**Adults.** 2 or 4 g once daily.

## Mechanism of Action

Possibly reduces synthesis of triglycerides in the liver by inhibiting acyl-CoA-1,2 diacylglycerol acyltransferase, increasing mitochondrial and peroxisomal beta oxidation in the liver, decreasing lipogenesis in the liver, and increasing plasma lipoprotein lipase activity.

## Contraindications

Hypersensitivity to omega 3-carboxylic acids or its components

## Interactions

### DRUGS

*anticoagulants, antiplatelet agents:* Possibly increased risk of bleeding

## Adverse Reactions

**CNS:** Fatigue

**CV:** Elevated LDL-C levels

**EENT:** Difficulty swallowing, nasopharyngitis

**GI:** Abdominal discomfort, distention, or pain; constipation; diarrhea; eructation; flatulence; nausea; vomiting

**MS:** Arthralgia

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients with fish and/or shellfish allergy because omega 3-carboxylic acids contain polyunsaturated free fatty acids derived from fish oils and it is not known if cross-sensitivity exists.
- Monitor LDL-C levels, as ordered, periodically during therapy with omega 3-carboxylic acids because drug may increase these levels in some patients.

## PATIENT TEACHING

- Instruct patient to swallow capsules whole and not to break open, chew, crush, or dissolve the capsules.
- Advise patient that if a dose is missed, take it as soon as it is remembered, but never to double the next dose to make up for the missed dose.
- Inform patient that drug therapy is not a substitution for dietary measures. Adherence to dietary restrictions must be continued.
- Tell patient to notify prescriber if any signs or symptoms of an allergic reaction occur and to seek immediate emergency care, if severe.

**omeprazole**

**Losec (CAN), Prilosec**

**omeprazole magnesium**

**Prilosec, Prilosec OTC**

## Class and Category

*Pharmacologic class:* Proton pump inhibitor

*Therapeutic class:* Antiulcer

# Indications and Dosages

- *To treat symptomatic gastroesophageal reflux disease (GERD)*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE TABLETS, DELAYED-RELEASE ORAL SUSPENSION**

**Adults and adolescents 16 years and over.** 20 mg daily for 4 wk.

**Children age 1 to 16 years of age weighing 20 kg (44 lb) or more.** 20 mg once daily for up to 4 wk.

**Children age 1 to 16 weighing 10 kg (22 lb) to less than 20 kg (44 lb).** 10 mg once daily for up to 4 wk.

**Children age 1 to 16 weighing 5 kg (11 lb) to less than 10 kg (22 lb).** 5 mg once daily for up to 4 wk.

- *To treat erosive esophagitis due to acid-mediated GERD*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION**

**Adults and adolescents age 16 and over.** 20 mg daily for 4 to 8 wk.

- *To treat pediatric erosive esophagitis due to acid-mediated GERD*

## **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION**

**Children age 1 to 16 years of age weighing 20 kg (44 lb) or more.** 20 mg daily for 4 to 8 wk.

**Children age 1 to 16 weighing 10 kg (22 lb) to less than 20 kg (44 lb).** 10 mg daily for 4 to 8 wk.

**Children age 1 to 16 weighing 5 kg (11 lb) to less than 10 kg (22 lb).** 5 mg daily for 4 to 8 wk.

**Children ages 1 month to less than 1 year weighing 10 kg (22 lb) or more.** 10 mg once daily up to 6 wk.

## Mechanism of Action

Omeprazole interferes with gastric acid secretion by inhibiting the hydrogen potassium adenosine triphosphatase ( $H^+ K^+ -ATPase$ ) enzyme system, or proton pump, in gastric parietal cells. Normally, the proton pump uses energy from hydrolysis of adenosine triphosphate to drive hydrogen ( $H^+$ ) and chloride ( $Cl^-$ ) out of parietal cells and into the stomach lumen in exchange for potassium ( $K^+$ ), which leaves the stomach lumen and enters parietal cells. After this exchange,  $H^+$  and  $Cl^-$  combine in the stomach to form hydrochloric acid ( $HCl$ ), as shown below left. Omeprazole irreversibly blocks the exchange of intracellular  $H^+$  and extracellular  $K^+$ , as shown below right. By preventing  $H^+$  from entering the stomach lumen, omeprazole keeps additional  $HCl$  from forming.

## Description

**Children ages 1 month to less than 1 year weighing 5 kg (11 lb) to less than 10 kg (22 lb).** 5 mg once daily up to 6 wk.

**Children ages 1 month to less than 1 year weighing 3 kg (6.6 lb) to less than 5 kg (11 lb).** 2.5 mg once daily up to 6 wk.

- *To provide maintenance of healing of erosive esophagitis due to acid-mediated GERD*

### **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION**

**Adults and adolescents age 16 and over.** 20 mg once daily up to 12 mo.

**Children age 1 to 16 years of age weighing 20 kg (44 lb) or more.** 20 mg once daily up to 12 mo.

**Children age 1 to 16 weighing 10 kg (22 lb) to less than 20 kg (44 lb).** 10 mg once daily up to 12 mo.

**Children age 1 to 16 weighing 5 kg (11 lb) to less than 10 kg (22 lb).** 5 mg once daily for up to 12 mo.

***DOSAGE ADJUSTMENT*** For adult patients with hepatic impairment and Asian patients, dosage reduced to 10 mg once daily.

- *To provide short-term treatment of active benign gastric ulcer*

### **DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION**

**Adults.** 40 mg daily for 4 to 8 wk.

- *To treat active duodenal ulcer short-term*

## DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION

**Adults.** 20 mg once daily for 4 wk, with an additional 4 wk of therapy, as needed.

- *To eradicate *Helicobacter pylori* in order to reduce risk of duodenal ulcer recurrence*

## DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION

**Adults.** 40 mg daily with clarithromycin 500 mg three times daily for 14 days. If ulcer present at start of therapy, 20 mg daily for an additional 14 days. Alternatively, 20 mg twice daily with amoxicillin 1,000 mg twice daily, and clarithromycin 500 mg twice daily for 10 days. If ulcer present at start of therapy, 20 mg once daily for an additional 18 days.

- *To provide long-term treatment of gastric hypersecretory conditions, such as multiple endocrine adenoma syndrome, systemic mastocytosis, and Zollinger-Ellison syndrome*

## DELAYED-RELEASE CAPSULES, DELAYED-RELEASE ORAL SUSPENSION

**Adults.** 60 mg daily or in divided doses for doses greater than 80 mg. *Maximum:* 120 mg three times daily.

Route	Onset	Peak	Duration
P.O.	1 hr	In 2 hr	72-96 hr

## Contraindications

Concurrent therapy with rilpivirine-containing products;  
hypersensitivity to omeprazole, substituted benzimidazoles,  
or their components

## Interactions

### DRUGS

*atazanavir, nelfinavir, rilpivirine*: Decreased plasma levels  
of these agents; promote drug resistance to these drugs

*cilostazol, diazepam, digoxin, phenytoin, tacrolimus*:

Increased exposure of these drugs

*citalopram*: Increased exposure of citalopram leading to  
increased risk of QT prolongation

*clopidogrel*: Reduced effectiveness of clopidogrel

*CYP2C19 or CYP3A4 inducers such as rifampin, St. John's*

*Wort*: Decreased exposure of omeprazole

*CYP2C19 or CYP3A4 inhibitors such as voriconazole*:

Increased exposure of omeprazole

*dasatinib, erlotinib, iron salts, itraconazole, ketoconazole,*

*mycophenolate mofetil, nilotinib*: Reduced absorption of  
these drugs

*methotrexate*: Possibly delayed methotrexate elimination  
and increased risk of toxicity

*saquinavir*: Increased plasma saquinavir level and risk of  
toxicity

*St. John's wort, rifampin*: Decreased plasma omeprazole  
level

*warfarin*: Possibly increased risk of abnormal bleeding

## Adverse Reactions

**CNS**: Agitation, asthenia, dizziness, drowsiness, fatigue,  
fever, headache, malaise, psychic disturbance, somnolence

**CV**: Chest pain, hypertension, peripheral edema

**EENT:** Anterior ischemic optic neuropathy, optic atrophy or neuritis, otitis media, stomatitis

**ENDO:** **Hypoglycemia**

**GI:** Abdominal pain, acid regurgitation, constipation, diarrhea, ***Clostridium difficile-associated diarrhea***, dyspepsia, elevated liver enzymes, flatulence, fundic gland polyps (long-term use), **hepatic dysfunction or failure**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Interstitial nephritis

**HEME:** **Agranulocytosis**, anemia, **hemolytic anemia**, **leukopenia**, leukocytosis, **neutropenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Back pain, bone fracture, joint pain

**RESP:** **Bronchospasms**, cough, upper respiratory infection

**SKIN:** Cutaneous lupus erythematosus, **erythema multiforme**, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hypomagnesemia**, **hyponatremia**, systemic lupus erythematosus, vitamin B<sub>12</sub> deficiency (long-term use)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug may be present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Give omeprazole before meals, preferably in the morning for once-daily dosing. If needed, also give an antacid, as prescribed.
- If needed, open capsule and sprinkle enteric-coated granules on applesauce or yogurt or mix with water or acidic fruit juice, such as apple or cranberry juice. Give immediately.
- Give drug via NG tube, when needed by mixing granules in acidic juice, because enteric coating dissolves in alkaline pH, or using the delayed-release oral suspension form by mixing with water.
- Know that because drug can interfere with absorption of vitamin B<sub>12</sub>, monitor patient for macrocytic anemia.
- Monitor patient for bone fracture, especially in patients receiving multiple daily doses for more than a year because proton pump inhibitors, such as omeprazole, increase risk for osteoporosis-related fractures of the hip, spine, or wrist.
- Be aware that long-term use of omeprazole may increase the risk of gastric carcinoma and symptomatic response to omeprazole therapy does not rule out the presence of gastric tumors.
- Know that omeprazole therapy may produce false elevations of serum chromogranin levels, used to help diagnosis presence of neuroendocrine tumors. If test results are high, withhold omeprazole therapy temporarily and repeat test, as ordered.
- Keep in mind that if omeprazole is given with antibiotics, watch for diarrhea from *C. difficile*. If diarrhea occurs, notify prescriber and expect to withhold drug and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient's urine output because omeprazole may cause acute interstitial nephritis. Notify prescriber if urine output decreases or there is blood in patient's urine.
- Monitor the patient, especially the patient on long-term therapy, for hypomagnesemia. If patient is to remain on omeprazole long term, expect to monitor the patient's serum magnesium level, as ordered, and if level becomes low, anticipate magnesium replacement therapy and omeprazole to be discontinued.

- Know that both cutaneous and systemic lupus erythematosus have occurred within days to years after proton pump therapy such as omeprazole was initiated. The most common symptoms presented were arthralgia, cytopenia, and rash. Report such findings to prescriber.
- Know that proton pump inhibitors such as omeprazole should not be prescribed longer than medically necessary.

## **PATIENT TEACHING**

- Tell patient to take drug before eating—usually before breakfast—and to swallow delayed-release capsules or tablets whole. If needed, patient may sprinkle contents of capsule onto 1 tablespoon of applesauce and swallow immediately without chewing pellets. Tell him to follow with a glass of cool water and not to keep any leftover mixture.
- Tell patient prescribed the oral suspension form to empty package into a small cup containing 2 tablespoons of water (no other beverage should be used), stir the mixture well, drink it immediately, refill the cup with water, and drink again.
- Encourage patient to avoid alcohol, aspirin products, ibuprofen, and foods that may increase gastric secretions during therapy. Tell him to notify all prescribers about prescription drug use.
- Advise patient to notify prescriber immediately about abdominal pain or diarrhea. Also, tell patient to stop taking omeprazole and notify prescriber if a rash or joint pain occurs.
- Urge female patient of childbearing age to use effective contraception during therapy and to inform prescriber immediately if she is or suspects she may be pregnant.
- Instruct patient to inform all prescribers of omeprazole therapy.
- Advise patient to notify prescriber if patient notices he is experiencing a decrease in the amount of urine voided or there is blood in his urine. Also tell him to notify prescriber if he experiences new or worsening joint pain or a rash on his arms or cheeks that gets worse in the sun.

**ondansetron**

**Zofran ODT, Zuplenz**

# ondansetron hydrochloride

**Zofran**

## Class and Category

*Pharmacologic class:* Selective serotonin (5-HT<sub>3</sub>) receptor antagonist

*Therapeutic class:* Antiemetic

## Indications and Dosages

- *To prevent nausea and vomiting associated with highly emetogenic cancer chemotherapy*

### **DISINTEGRATING TABLETS, ORAL SOLUTION, ORAL SOLUBLE FILM, TABLETS**

**Adults.** 24 mg 30 min before chemotherapy. Films and disintegrating tablets given as three 8-mg doses (allowing each 8-mg film or disintegrating tablet to dissolve completely before another given).

### **I.V. INFUSION**

**Adults and children ages 6 months to 18 years.** Three 0.15-mg/kg doses, each infused over 15 min, starting with first dose given 30 min before chemotherapy and second and third doses given 4 and 8 hr after first dose. *Maximum:* 16 mg per dose.

- *To prevent nausea and vomiting associated with moderately emetogenic cancer chemotherapy*

## **DISINTEGRATING TABLETS, ORAL SOLUTION, ORAL SOLUBLE FILM, TABLETS**

**Adults and adolescents age 12 and over.** *Initial:* One 8-mg dose given 30 min before chemotherapy and one 8-mg dose given 8 hr after the first dose. Then, one 8-mg dose given every 12 hr for 1 to 2 days after completion of chemotherapy.

**Children ages 4 to 11.** *Initial:* One 4-mg dose given 30 min before chemotherapy with one 4-mg dose given 4 and 8 hr after the first dose. Then, one 4-mg dose given every 8 hr for 1 to 2 days after completion of chemotherapy.

- *To prevent nausea and vomiting associated with initial and repeat courses of emetogenic chemotherapy*

## **I.V. INFUSION**

**Adults and children ages 6 months to 18 years.** Three 0.15-mg/kg doses, each infused over 15 min, starting with first dose given 30 min before chemotherapy and second and third doses given 4 and 8 hr after first dose. *Maximum:* 16 mg per dose.

- *To prevent nausea and vomiting associated with radiotherapy in patients receiving either total body irradiation, single high-dose fraction to the abdomen, or daily fractions to the abdomen*

## **DISINTEGRATING TABLETS, ORAL SOLUTION, ORAL SOLUBLE FILM, TABLETS**

**Adults receiving total body irradiation.** 8 mg dose given 1 to 2 hr before each fraction of radiotherapy administered each day.

**Adults receiving single high-dose fraction radiotherapy to the abdomen.** 8 mg dose given 1 to 2 hr before radiotherapy, with subsequent 8 mg doses given

every 8 hr after the first dose for 1 to 2 days after completion of radiotherapy.

**Adults receiving daily fractionated radiotherapy to the abdomen.** 8 mg dose given 1 to 2 hr before radiotherapy with subsequent 8 mg doses given every 8 hr after the first dose for each day radiotherapy is given.

➤ *To prevent postoperative nausea and vomiting*

## **DISINTEGRATING TABLETS, ORAL SOLUTION, TABLETS**

**Adults.** 16 mg as a single dose 1 hr before anesthesia induction.

## **ORAL SOLUBLE FILM**

**Adults.** 16 mg given as two 8-mg films (first 8-mg film allowed to dissolve completely before second 8-mg film given) 1 hr before induction of anesthesia.

## **I.V. INJECTION**

**Adults and children age 12 and over.** 4 mg undiluted as a single dose over 2 to 5 min just before anesthesia induction or if nausea or vomiting develops within 2 hr after surgery, providing no prophylactic antiemetics had been given preoperatively.

**Children ages 2 to 12 weighing more than 40 kg (88 lb).** 4 mg as a single dose over 2 to 5 min just before anesthesia induction or if nausea or vomiting develops within 2 hr after surgery, providing no prophylactic antiemetics had been given preoperatively.

**Children ages 1 month to 12 years weighing 40 kg (88 lb) or less.** 0.1 mg/kg as a single dose over 2 to 5 min just before or immediately after anesthesia induction or if nausea or vomiting develops within 2 hr after surgery,

providing no prophylactic antiemetics had been given preoperatively.

## **I.M. INJECTION**

**Adults and children age 12 and over.** 4 mg undiluted as a single dose just before anesthesia induction or if nausea within 2 hr after surgery, providing no prophylactic antiemetics had been given preoperatively.

**DOSAGE ADJUSTMENT** For patients with severe hepatic impairment, maximum dosage limited to 8 mg daily I.V. or P.O.

## **Mechanism of Action**

Blocks serotonin receptors centrally in the chemoreceptor trigger zone and peripherally at vagal nerve terminals in the intestine. This action reduces nausea and vomiting by preventing serotonin release in the small intestine (probable cause of chemotherapy- and radiation-induced nausea and vomiting) and by blocking signals to the CNS. Ondansetron may also bind to other serotonin receptors and to mu-opioid receptors.

## **Incompatibilities**

Don't give ondansetron in same I.V. line as acyclovir, allopurinol, aminophylline, amphotericin B, ampicillin, ampicillin and sulbactam, amsacrine, cefepime, cefoperazone, furosemide, ganciclovir, lorazepam, methylprednisolone, mezlocillin, piperacillin, or sargramostim. Alkaline solutions and highly concentrated fluorouracil solutions are physically incompatible.

## **Contraindications**

Concomitant use of apomorphine, hypersensitivity to ondansetron or its components

## Interactions

### DRUGS

*5-HT<sub>3</sub> receptor antagonists, selective serotonin reuptake inhibitors, serotonin and noradrenaline reuptake inhibitors:* Increased risk of serotonin syndrome  
*carbamazepine, phenytoin, rifampin:* Possibly decreased ondansetron blood concentrations  
*tramadol:* Possibly interference with pain control from tramadol

## Adverse Reactions

**CNS:** Agitation, akathisia, anxiety, ataxia, dizziness, drowsiness, dystonia, fever, headache, **hypotension**, restlessness, seizures, **serotonin syndrome**, syncope, somnolence, thirst, weakness

**CV:** **Arrhythmias**, **cardiopulmonary arrest** (parenteral form), chest pain, **hypotension**, palpitations, **prolonged QT interval**, **shock**, tachycardia, **torsades de pointes**,

**EENT:** Accommodation disturbances, altered taste, blurred vision, dry mouth, **laryngeal edema**, **laryngospasm**, **stridor**, transient blindness

**GI:** Abdominal pain, anorexia, constipation, diarrhea, elevated liver enzymes, flatulence, indigestion, **intestinal obstruction**, masking of progressive gastric and ileus distention

**RESP:** **Bronchospasms**, **pulmonary embolism**, shortness of breath

**SKIN:** Flushing, hyperpigmentation, maculopapular rash, pruritus, **Stevens-Johnson syndrome**, **toxic epidermal**

**necrolysis**, urticaria

**Other:** **Anaphylaxis**; **angioedema**; hiccups; injection-site burning, pain, and redness

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Be aware that oral disintegrating tablets may contain aspartame, which is metabolized to phenylalanine and must be avoided in patients with phenylketonuria.

- Know that if hypokalemia or hypomagnesemia is present, these electrolyte imbalances should be corrected before ondansetron is administered because of increased risk for QT-interval prolongation, which could predispose the patient to develop torsades de pointes.
- Place disintegrating tablet or oral soluble film on patient's tongue immediately after opening package. It dissolves in seconds.
- Use calibrated container or oral syringe to measure dose of oral solution.
- Dilute drug in 50 ml of D<sub>5</sub>W or normal saline solution when indicated. However, know that when used to treat postoperative nausea and vomiting in adults, drug is administered undiluted intramuscularly or intravenously.

- Monitor patient closely for signs and symptoms of hypersensitivity to ondansetron because hypersensitivity reactions, including anaphylaxis and bronchospasm, may occur. If present, discontinue drug, notify prescriber, and provide supportive care.

**WARNING** Monitor patient closely for serotonin syndrome, which may include agitation, chills, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching.

- Monitor patient's electrocardiogram, as ordered, and especially in patients with bradyarrhythmias, congestive heart failure, hypokalemia, or hypomagnesemia or in patients taking other medications known to prolong the QT interval because ondansetron therapy can prolong the QT interval resulting in life-threatening arrhythmias such as torsades de pointes. Be aware that no dosage greater than 16 mg should be given intravenously at any one time due to increased risk of prolonged QT interval.

**WARNING** Be aware that ondansetron may mask symptoms of adynamic progressive ileus or gastric distention after abdominal surgery. Monitor patient for decreased bowel activity, especially if patient has risk factors for gastrointestinal obstruction.

## **PATIENT TEACHING**

- Advise patient to use calibrated container or oral syringe to measure oral solution.

**WARNING** Tell patient that oral disintegrating tablets may contain aspartame, which is metabolized to phenylalanine and must be used cautiously in patients with phenylketonuria. Tell patient each 4- and 8-mg orally disintegrating tablet contains less than 0.03 mg phenylalanine.

- Instruct patient to place ondansetron disintegrating tablet or oral soluble film on his tongue immediately after opening package and to let it dissolve on his tongue before swallowing.
- Advise patient to immediately report signs of hypersensitivity, such as rash.

**WARNING** Advise patients to seek immediate medical attention if patient experiences persistent, severe, unusual, or worsening symptoms.

- Reassure patient with transient blindness that it will resolve within a few minutes to 48 hours.

## oritavancin diphosphate

### Orbactiv

## Class and Category

*Pharmacologic class:* Lipoglycopeptide

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat acute bacterial skin and skin structure infections caused by gram-positive microorganisms such as Enterococcus faecalis (vancomycin-susceptible isolates only), Staphylococcus aureus (including methicillin-susceptible and methicillin-resistant isolates), Streptococcus agalactiae, S. dysgalactiae, S. anginosus group (S. anginosus, S. constellatus, S. intermedius), and S. pyogenes*

## **I.V. INFUSION**

**Adults.** 1,200 mg given over 3 hr as a one-time dose.

## **Mechanism of Action**

Kills bacteria by inhibiting cell wall synthesis.

## **Incompatibilities**

Do not mix or administer oritavancin in normal saline solution, as a precipitation of the drug may occur. Also, do not administer with other drugs, including those formulated at a basic or neutral pH, as they may be incompatible with oritavancin.

## **Contraindications**

Hypersensitivity to oritavancin and its components, intravenous unfractionated heparin sodium administration used within 5 days following oritavancin administration

## **Interactions**

### **DRUGS**

*drugs with a narrow therapeutic window that are predominantly metabolized by CYP450 enzymes:* Possibly decreased or increased concentration of these drugs  
*warfarin:* Increased risk of bleeding

## **Adverse Reactions**

**CNS:** Dizziness, headache

**CV:** Peripheral edema, tachycardia

**ENDO:** Hypoglycemia

**GI:** *Clostridium difficile*-associated diarrhea, diarrhea, elevated liver enzymes, nausea, vomiting

**HEME:** Anemia, eosinophilia

**MS:** Myalgia, osteomyelitis, tenosynovitis

**RESP:** Bronchospasm, wheezing

**SKIN:** Erythema multiforme, leucocytoclastic vasculitis, pruritus, rash, urticaria

**Other:** Anaphylaxis; angioedema; hyperuricemia; infusion reactions such as back or chest pain; chills; erythema, flushing of the upper body, pruritus, tremor; or urticaria; infusion-site extravasation, induration, or phlebitis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use oritavancin cautiously in patients with a history of hypersensitivity to glycopeptides because of the possibility of cross-sensitivity.
- Reconstitute drug by adding 40 ml of sterile water for injection to each vial (three vials are needed to provide a dose of 1,200 mg), to provide a 10 mg/ml solution per vial. Gently swirl to avoid foaming and to completely

dissolve the powder. Solution should appear clear, colorless to pale yellow.

- Withdraw and discard 120 ml from a 1,000-ml intravenous bag of D5W (never use normal saline). Then, withdraw 40 ml from each of the three reconstituted vials and add to D5W intravenous bag to bring bag volume back to 1,000 ml. This will yield a concentration of 1.2 mg/ml. Once mixed in infusion bag, use within 3 hours when stored at room temperature or within 9 hours when refrigerated to allow the additional 3 hours needed for administration.
- Monitor patient for infusion reactions such as red man syndrome, including flushing of the upper body, pruritus, rash, and/or urticaria. Notify prescriber immediately, because slowing or stopping the infusion may resolve these symptoms.
- Flush intravenous line with D5W solution before and after administering drug.
- Monitor patient closely for signs of bleeding, especially if patient is taking warfarin therapy, because drug may artificially prolong prothrombin time (PT) and INR for up to 12 hours, making monitoring of the effectiveness of warfarin unreliable for at least 12 hours after the administration of oritavancin. Drug may also artificially prolong activated partial thromboplastin time (aPTT) for up to 120 hours and activated clotting time (ACT) for up to 24 hours after a single 1,200-mg dose of oritavancin.
- Infuse oritavancin over 3 hours. If patient develops an infusion-related reaction such as flushing, pruritus, or urticaria, slow or stop the infusion and notify prescriber.

**WARNING** Monitor patient closely for signs of hypersensitivity reactions because some reactions may be serious. If present, discontinue infusion immediately, notify prescriber, and implement appropriate standard of care.

- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *C. difficile*. If confirmed, expect to withhold drug and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Monitor patient for osteomyelitis, as drug has been shown to produce more cases of osteomyelitis than vancomycin used to treat similar

infections. If present, be prepared to institute appropriate alternative antibacterial therapy.

## PATIENT TEACHING

- Alert patient that an allergic reaction can occur up to a day after oritavancin has been administered. Instruct him to notify prescriber of any signs of an allergic reaction and seek immediate medical attention if signs are severe or prolonged.
- Urge patient to tell prescriber if diarrhea develops, even 2 months or more after oritavancin ends.

## oseltamivir phosphate

### Tamiflu

## Class and Category

*Pharmacologic class:* Selective neuraminidase inhibitor

*Therapeutic class:* Antiviral

## Indications and Dosages

- *To treat acute uncomplicated illness due to influenza A and B infection in patients who have been symptomatic for no more than 48 hours*

## CAPSULES, ORAL SUSPENSION

**Adults and adolescents.** 75 mg twice daily for 5 days.

**Children ages 1 to 12 years weighing more than 40 kg (88 lb).** 75 mg twice daily.

**Children ages 1 to 12 years weighing 23.1 kg (50.82 lb) to 40 kg (88 lb).** 60 mg twice daily.

**Children ages 1 to 12 years weighing 15.1 kg (33.22 lb) to 23 kg (50.6 lb).** 45 mg twice daily.

**Children ages 1 to 12 years weighing 15 kg (33 lb) or less.** 30 mg twice daily.

**Infants 2 weeks to less than 1 year at any weight.** 3 mg/kg twice daily.

➤ *To prevent influenza A and B infection*

## **CAPSULES, ORAL SUSPENSION**

**Adults and adolescents.** 75 mg once daily for at least 10 days following close contact with an infected individual, up to 6 wk during a community outbreak, and up to 12 wk for immunocompromised patients.

**Children ages 1 to 12 years weighing more than 40.1 kg (88 lb).** 75 mg once daily for at least 10 days following close contact with an infected individual, up to 6 wk during a community outbreak, and up to 12 wk for immunocompromised patients.

**Children ages 1 to 12 years weighing 23.1 kg (50.82 lb) to 40 kg (88 lb).** 60 mg once daily for at least 10 days following close contact with an infected individual, up to 6 wk during a community outbreak, and up to 12 wk for immunocompromised patients.

**Children ages 1 to 12 years weighing 15.1 (33.22 lb) to 23 kg (50.6 lb).** 45 mg once daily for at least 10 days following close contact with an infected individual, up to 6 wk during a community outbreak, and up to 12 wk for immunocompromised patients.

**Children ages 1 to 12 years weighing 15 kg (33 lb) or less.** 30 mg once daily for at least 10 days following close contact with an infected individual, up to 6 wk during a

community outbreak, and up to 12 wk for immunocompromised patients.

**DOSAGE ADJUSTMENT** For adult patients with a creatinine clearance between 30 and 60 ml/min, dosage reduced to 30 mg twice daily for 5 days to treat influenza A and B infection and 30 mg once daily to prevent influenza A and B infection for 10 days. For adult patients with a creatinine clearance of between 10 to 30 ml/min, dosage reduced to 30 mg once daily for 5 days to treat influenza A and B infection and 30 mg every other day to prevent influenza A and B infection for 10 days. For adult patients with end-stage renal disease on hemodialysis, dosage reduced to 30 mg given immediately and then 30 mg after each hemodialysis cycle (treatment duration not to exceed 5 days) to treat influenza A and B infection and 30 mg given immediately and then 30 mg after alternate hemodialysis cycles to prevent influenza A and B infection for 10 days. For patients with end-stage renal disease on continuous ambulatory peritoneal dialysis, dosage reduced to a single 30-mg dose administered immediately to treat influenza A and B infection and 30 mg given immediately and then 30 mg once weekly to prevent influenza A and B infection for 10 days.

## **Mechanism of Action**

After conversion to its active form, oseltamivir inhibits influenza virus neuraminidase, affecting release of viral particles.

## **Contraindications**

Hypersensitivity to oseltamivir phosphate or its components

# Interactions

## DRUGS

*live attenuated influenza vaccine (intranasal)*: Possibly decreased effectiveness

## Adverse Reactions

**CNS:** Abnormal behavior, agitation, altered level of consciousness, anxiety, delirium, delusions, headache, **hypothermia**, nightmares, **seizures**

**CV:** **Arrhythmia**

**ENDO:** Aggravation of diabetes mellitus

**GI:** Diaper rash, diarrhea, elevated liver enzymes, **GI bleeding**, **hemorrhagic colitis**, **hepatitis**, nausea, vomiting

**SKIN:** Dermatitis, eczema, **erythema multiforme**, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, generalized pain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

**WARNING** Monitor patient for serious hypersensitivity and skin reactions when administering oseltamivir. Know that anaphylaxis and skin reactions such as erythema multiforme, Stevens–Johnson syndrome, and toxic epidermal necrolysis have occurred. If present, discontinue oseltamivir therapy immediately, notify prescriber, and be prepared to provide emergency supportive care as ordered.

- Be aware that although uncommon, abnormal behavior and delirium have occurred after administration of oseltamivir, especially in children. While the onset is abrupt, rapid resolution usually occurs once oseltamivir is discontinued.

## PATIENT TEACHING

- Instruct patient that for oseltamivir to be most effective, therapy should begin as soon as possible with the first appearance of flu symptoms: no later than 48 hours of onset of symptoms and as soon as possible after exposure.
- Tell patient to take a missed dose as soon as he remembers it, except if it is within 2 hours of the next scheduled dose.
- Warn patient that oral suspension contains above-normal maximum daily limits of sorbitol and may cause dyspepsia and diarrhea, especially in patients with hereditary fructose intolerance.
- Inform patient who cannot swallow capsules, when oral suspension is not available, that capsules may be opened and mixed with sweetened liquids such as caramel topping, corn syrup, light brown sugar dissolved in water, or regular or sugar-free chocolate syrup.
- Instruct patient, parent, or caregiver to use the oral dispenser device that comes with the product.
- Instruct patient that oral suspension can be stored in the refrigerator for up to 17 days before discarding. Caution against freezing.

**WARNING** Advise patient to seek immediate medical attention if he experiences an allergic reaction or unusual or severe skin reactions.

- Alert patient and parents that, although uncommon, abnormal behavior and delirium have occurred, especially in children. Notify prescriber if present and expect drug to be discontinued.
- Inform patient that oseltamivir is not a substitute for receiving an annual flu vaccination.

## oxandrolone

### Oxandrin

## Class, Category, and Schedule

*Pharmacologic class:* Androgen

*Therapeutic class:* Appetite stimulant

Controlled substance schedule: III

## Indications and Dosages

- *As adjunct to offset protein catabolism from prolonged use of corticosteroids; to provide relief of bone pain from osteoporosis*

### TABLETS

**Adults.** 2.5 to 20 mg in divided doses given twice daily to four times a day for 2 to 4 wk; intermittent therapy repeated as prescribed. *Maximum:* 20 mg daily.

**Children.** 0.1 mg/kg or less daily; intermittent therapy repeated as prescribed.

## Mechanism of Action

Promotes tissue-building processes and reverses catabolic or tissue-depleting processes by promoting protein anabolism.

## Contraindications

Breast cancer (males); breast cancer with hypercalcemia (females); hypercalcemia; hypersensitivity to oxandrolone, anabolic steroids, or their components; nephrosis; pregnancy; prostate cancer

## Interactions

### DRUGS

*ACTH, adrenal steroids:* Increased risk of edema

*oral hypoglycemic agents:* Inhibited metabolism of these drugs

*warfarin:* Increased risk anticoagulant effect

## Adverse Reactions

**CNS:** Depression, excitement, insomnia

**CV:** Decreased serum HDL level, edema, hyperlipidemia, hypertension

**ENDO:** Feminization in postpubertal males (epididymitis, gynecomastia, impotence, oligospermia, priapism, testicular atrophy); glucose intolerance; virilism in females (acne, clitoral enlargement, decreased breast size, deepened voice, diaphoresis, emotional lability, flushing,

hirsutism, hoarseness, libido changes, male-pattern baldness, menstrual irregularities, nervousness, oily skin or hair, vaginal bleeding, vaginitis, weight gain), virilism in prepubertal males (acne, decreased ejaculatory volume, penis enlargement, prepubertal closure of epiphyseal plates, unnatural growth of body and facial hair)

**GI:** Diarrhea, elevated liver enzymes, **hepatocellular carcinoma**, jaundice, nausea, vomiting

**GU:** Benign prostatic hyperplasia, **prostate cancer**, urinary frequency, urine retention (elderly men)

**HEME:** Iron deficiency anemia, **leukemia**, **prolonged bleeding time**

**Other:** Fluid retention, **hypercalcemia** (females), physical and psychological dependence, sodium retention

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

### REPRODUCTION

- Women of childbearing age should use an effective contraceptive throughout drug therapy.

## Nursing Considerations

- Use oxandrolone cautiously in patients with heart disease because drug has hypercholesterolemic effects.
- Provide adequate calories and protein, as ordered, to maintain a positive nitrogen balance during oxandrolone therapy.
- Anticipate an increased risk of fluid and sodium retention in patients with cardiac, hepatic, or renal dysfunction.
- Weigh patient daily to detect fluid retention. If patient has fluid retention, expect a sodium-restricted diet or diuretics.
- Monitor blood glucose level frequently in patient with diabetes mellitus.
- Know that if patient takes an oral anticoagulant, check INR or PT should be checked as ordered.

## **PATIENT TEACHING**

- Advise patient to consume a diet high in calories and protein to achieve maximum therapeutic effect of oxandrolone.
- Urge patient to weigh himself daily during therapy and to report swelling or unexplained weight gain at once.
- Explain that drug may alter libido.
- Inform woman that drug may cause permanent physical changes, such as clitoral enlargement, deepened voice, and hair growth.
- Advise female patient of childbearing age that she must use contraception during oxandrolone therapy and should notify prescriber immediately about suspected or known pregnancy.
- Instruct diabetic patient to monitor blood glucose level frequently.
- Advise bleeding precautions (such as an electric shaver and soft toothbrush) if patient takes warfarin. Tell patient to notify prescriber immediately if bleeding occurs.

**oxaprozin**

**Daypro**

# oxaprozin potassium

**Daypro Alta**

## Class and Category

*Pharmacologic class:* NSAID

*Therapeutic class:* Anti-inflammatory, antirheumatic

## Indications and Dosages

➤ *To treat osteoarthritis and rheumatoid arthritis*

### **TABLETS**

**Adults.** *Initial:* 1,200 mg once daily. Dosage adjusted based on response. *Maximum:* 1,800 mg daily or 26 mg/kg daily (whichever is less) in divided doses.

***DOSAGE ADJUSTMENT*** Initial dose limited to 600 mg daily for patients with low body weight or severe renal impairment.

➤ *To treat juvenile rheumatoid arthritis*

### **TABLETS**

**Children ages 6 to 16 years weighing 55 kg (121 lb) or more.** 1,200 mg once daily.

**Children ages 6 to 16 weighing 32 to 54 kg (70.4 to 118.8 lb).** 900 mg once daily.

**Children ages 6 to 16 weighing 22 to 31 kg (48.4 to 68.2).** 600 mg once daily.

Route	Onset	Peak	Duration
P.O.	In 7 days	Unknown	Unknown

# Mechanism of Action

Blocks cyclooxygenase, the enzyme needed to synthesize prostaglandins, which mediate the inflammatory response and cause local vasodilation, pain, and swelling. By blocking cyclooxygenase and prostaglandins, the NSAID oxaprozin relieves pain.

# Contraindications

History of asthma, urticaria, or other allergic-type reactions after taking aspirin or other NSAIDs, hypersensitivity to oxaprozin or its components; postoperatively after coronary artery bypass graft (CABG) surgery

# Interactions

## DRUGS

*ACE inhibitors, angiotensin receptor blockers, beta-blockers:* Diminished antihypertensive effect of these drugs; possibly impaired renal function especially in the elderly and patients with existing renal impairment or volume depletion

*anticoagulants, antiplatelets, selective serotonin reuptake inhibitors, serotonin norepinephrine reuptake inhibitors:* Increased risk of bleeding

*aspirin:* Increased significant risk of GI bleeding reactions

*corticosteroids:* Increased risk of adverse GI effects

*cyclosporine:* Increased risk of nephrotoxicity

*digoxin:* Increased blood digoxin level and risk of digitalis toxicity

*diuretics:* Possibly decreased diuretic effect

*glyburide:* Possibly altered blood glucose level

*lithium*: Increased blood lithium level and increased risk of lithium toxicity

*methotrexate*: Increased blood methotrexate level and risk of methotrexate toxicity

*other NSAIDs, salicylates*: Increased GI irritability and bleeding

*pemetrexed*: Increased risk of pemetrexed-associated GI and renal toxicity, myelosuppression

## ACTIVITIES

*alcohol use, smoking*: Increased risk of adverse GI effects

## Adverse Reactions

**CNS:** Aseptic meningitis, confusion, CVA, dizziness, drowsiness, fatigue, headache, insomnia, nervousness, sedation, transient ischemic attacks, vertigo, weakness

**CV:** Deep vein thrombosis, hypertension, hypotension, MI, peripheral edema

**EENT:** Tinnitus

**ENDO:** Hypoglycemia

**GI:** Abdominal pain, constipation, diarrhea, dyspepsia, elevated liver enzymes, GI bleeding or ulceration, hepatitis, jaundice, liver failure, nausea, perforation of intestine or stomach, vomiting

**GU:** Acute renal failure, dysuria, interstitial nephritis, urinary frequency

**HEME:** Agranulocytosis, anemia, aplastic anemia, leukopenia, pancytopenia, thrombocytopenia

**SKIN:** Alopecia, erythema multiforme, exfoliative dermatitis, maculopapular rash, photosensitivity,

Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, angioedema

# Childbearing Considerations

## PREGNANCY

- Drug increases risk of premature closure of the fetal ductus arterisus if given during the third trimester of pregnancy.
- Drug should be avoided in pregnant women starting at 30 weeks of gestation and onward.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## REPRODUCTION

- Drug may delay or prevent rupture of ovarian follicles in females causing reversible infertility.
- Drug should not be used in women of childbearing age who have difficulty conceiving or who are undergoing investigation of infertility.

# Nursing Considerations

- Be aware that NSAIDs like oxaprozin should be avoided in patients with a recent MI because risk of reinfarction increases with NSAID therapy. If therapy is unavoidable, monitor patient closely for signs of cardiac ischemia.
- Know that the risk of heart failure increases with use of NSAIDs such as oxaprozin. NSAIDs should not be used in patients with severe heart failure, but if unavoidable, monitor patient for worsening of heart failure.
- Use oxaprozin with extreme caution in patients with a history of GI bleeding or ulcer disease because NSAIDs, such as oxaprozin, increase risk of GI bleeding and ulceration. Expect to use oxaprozin for the shortest time possible in these patients. Also know that other risk factors for GI bleeding in patients taking oxaprozin include advanced liver disease and/or coagulopathy; concomitant use of antiplatelets, anticoagulants,

oral corticosteroids, or selective serotonin reuptake inhibitors; poor general health: older age; smoking; and use of alcohol.

- Be aware that serious GI tract bleeding, perforation, and ulceration may occur without warning symptoms. Elderly patients are at greater risk. To minimize risk, give drug with food. If GI distress occurs, withhold drug and notify prescriber at once.
- Use oxaprozin cautiously in patients with hypertension, and monitor blood pressure closely throughout therapy. Drug may cause hypertension or worsen it.

**WARNING** Monitor patient closely for thrombotic events, including MI and stroke, because NSAIDs increase the risk. These events have occurred even in patients who do not have a history or risk factors for cardiovascular disease. Monitor patient for warning signs such as chest pain, slurring of speech, shortness of breath, or weakness. If present, withhold oxaprozin, alert prescriber immediately, and provide supportive care as prescribed.

**WARNING** If patient has bone marrow suppression or is receiving antineoplastic drug therapy, monitor laboratory results (including WBC count), and watch for evidence of infection because anti-inflammatory and antipyretic actions of oxaprozin may mask signs and symptoms, such as fever and pain.

- Watch for less common but serious adverse GI reactions, including anorexia, constipation, diverticulitis, dysphagia, esophagitis, gastritis, gastroenteritis, gastroesophageal reflux disease, hemorrhoids, hiatal hernia, melena, stomatitis, and vomiting. The risk is higher if patient is elderly or taking oxaprozin long term.
- Monitor liver enzymes because, in rare cases, elevated levels may progress to severe hepatic reactions, including fatal hepatitis, hepatic failure, and liver necrosis.
- Monitor BUN and serum creatinine levels in patients with heart failure, hepatic dysfunction, or impaired; those taking ACE inhibitors or diuretics; and elderly patients because drug may cause renal failure.

- Monitor CBC for decreased hemoglobin level and hematocrit because drug may worsen anemia.
- Assess patient's skin routinely for rash or other signs of hypersensitivity reaction because oxaprozin and other NSAIDs may cause serious skin reactions without warning, even in patients with no history of NSAID hypersensitivity. Stop drug at first sign of reaction, and notify prescriber.

## **PATIENT TEACHING**

- Instruct patient to take oxaprozin exactly as prescribed.
- Advise patient to take drug with a full glass of water and to stay upright for 15 to 30 minutes afterward to keep drug from lodging in esophagus and causing irritation.
- Urge patient to avoid alcohol as well as aspirin and other NSAIDs during oxaprozin therapy to avoid bleeding complications.
- Advise patient to avoid excessive sun exposure to reduce the risk of photosensitivity.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient that risk of bleeding may continue up to 2 weeks after stopping drug.
- Explain that oxaprozin may increase the risk of serious adverse cardiovascular reactions; urge patient to seek immediate medical attention if signs or symptoms arise, such as chest pain, edema, shortness of breath, slurring of speech, unexplained weight gain, or weakness.
- Inform patient that oxaprozin also may increase the risk of serious adverse GI reactions; stress need to seek immediate medical attention for such signs and symptoms as abdominal or epigastric pain, black or tarry stools, indigestion or vomiting blood, or material that looks like coffee grounds.
- Alert patient to rare but serious skin reactions. Urge him to seek immediate medical attention for blisters, fever, itching, rash, or other indications of hypersensitivity.

**oxazepam**

## Class, Category, and Schedule

*Pharmacologic class:* Benzodiazepine

*Therapeutic class:* Anxiolytic

*Controlled substance schedule:* IV

## Indications and Dosages

➤ *To treat anxiety*

### CAPSULES

**Adults.** 10 to 15 mg three times a day or four times a day for mild to moderate anxiety; up to 30 mg three times a day or four times a day for severe anxiety.

➤ *To help manage acute alcohol withdrawal symptoms*

### CAPSULES

**Adults.** 15 to 30 mg three times a day or four times a day.

***DOSAGE ADJUSTMENT*** For elderly or debilitated patients, initial dose of 10 mg three times a day increased cautiously to 15 mg three times a day or four times a day.

## Mechanism of Action

May potentiate the effects of gamma-aminobutyric acid (GABA) and other inhibitory neurotransmitters by binding to specific benzodiazepine receptors in limbic and cortical areas of the CNS. GABA inhibits excitatory stimulation, which helps control emotional behavior. The limbic system contains highly dense areas of benzodiazepine receptors, which may explain oxazepam's antianxiety effects.

## Contraindications

Hypersensitivity to oxazepam or its components

## Interactions

### DRUGS

*CNS depressants, opioids, other benzodiazepines:*  
Increased risk of severe CNS and respiratory depression

### ACTIVITIES

*alcohol use:* Increased risk of severe CNS and respiratory depression

## Adverse Reactions

**CNS:** Anxiety (in daytime), ataxia, confusion, depression, dizziness, drowsiness, fatigue, headache, insomnia, nightmares, sleep disturbance, slurred speech, syncope, talkativeness, tremor, vertigo

**GI:** Nausea

**Other:** Drug tolerance, physical and psychological dependence, withdrawal symptoms

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, use of other minor tranquilizers during the first trimester of pregnancy has shown an increased risk for congenital malformations.
- Maternal use of drug shortly before delivery may result in floppy infant syndrome.
- Drug should be avoided during pregnancy, if possible.

## LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy.

## Nursing Considerations

**WARNING** Oxazepam may cause physical and psychological dependence.

- Be aware that drug shouldn't be stopped abruptly after prolonged use; doing so may cause seizures or withdrawal symptoms, such as insomnia, irritability, and nervousness.
- Be aware that withdrawal symptoms can occur when therapy lasts only 1 or 2 weeks.

**WARNING** Be aware that oxazepam should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of oxazepam to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur. Monitor respiratory status in patients with pulmonary disease (such as severe COPD), respiratory depression, or sleep apnea; drug may worsen ventilatory failure.

- Expect an increased risk of falls among elderly patients from impaired cognition and motor function. Take safety precautions.
- Be aware that drug may worsen acute intermittent porphyria, myasthenia gravis, and severe renal impairment.

- Expect patient with late-stage Parkinson's disease to experience decreased cognition or coordination and, possibly, increased psychosis.

## PATIENT TEACHING

- Instruct patient to take oxazepam exactly as prescribed and not to stop taking it without consulting prescriber.
- Caution patient about possible drowsiness and reduced coordination.
- Urge patient to avoid alcohol, which increases oxazepam's sedative effects.

**WARNING** Alert patient to the drug interaction between oxazepam and opioids and not to combine the two unless directed to do so by a prescriber and only after prescriber has been informed of oxazepam therapy.

## oxcarbazepine

**Oxtellar XR, Trileptal**

## Class and Category

*Pharmacologic class:* Carboxamide derivative

*Therapeutic class:* Anticonvulsant

## Indications and Dosages

➤ *As adjunct to treat partial seizures*

## ORAL SUSPENSION, TABLETS (TRILEPTAL)

**Adults and adolescents over age 16.** *Initial:* 300 mg twice daily. Dosage increased by 600 mg/day every wk. *Usual:* 1,200 mg daily. *Maximum:* 2,400 mg daily.

**Children ages 2 to 16.** *Initial:* 4 to 5 mg/kg twice daily to maximum initial dose of 600 mg daily. *Usual:* 900 mg daily for children weighing 20 to 29 kg (44 to 64 lb); 1,200 mg daily for those weighing 29.1 to 39 kg (65 to 86 lb); 1,800 mg daily for those weighing more than 39 kg. *Maximum:* 1,800 mg daily.

**Children ages 2 to 4 weighing less than 20 kg (44 lb).** *Initial:* 16 to 20 mg/kg daily divided in a twice a day regimen, increased, as needed, over 2 to 4 wk. *Maximum:* 60 mg/kg/day in a twice a day regimen.

➤ *As monotherapy to treat partial seizures*

## **ORAL SUSPENSION, TABLETS (TRILEPTAL)**

**Adults and adolescents over age 16.** *Initial:* 300 mg twice daily. Dosage increased by 300 mg/day every 3 days, as needed. *Usual:* 1,200 mg daily. *Maximum:* 2,400 mg daily.

**Children ages 4 to 16.** *Initial:* 4 to 5 mg/kg twice daily, increased by 5 mg/kg daily every third day, as needed. *Maintenance:* Based on weight as follows: 70 kg (154 lb)-1,500 to 2,100 mg/day; 60 to 65 kg (132 to 143 lb)-1,200 to 2,100 mg/day; 50 to 55 kg (110 to 121 lb)-1,200 to 1,800 mg/day; 45 kg (99 lb)-1,200 to 1,500 mg/day; 35 to 40 kg (77 to 88 lb)-900 to 1,500 mg/day; 25 to 30 kg (55 to 66 lb)-900 to 1,200 mg/day; and 20 kg (44 lb): 600 to 900 mg/day.

➤ *To convert to monotherapy in treating partial seizures*

## **ORAL SUSPENSION, TABLETS (TRILEPTAL)**

**Adults and adolescents over age 16.** *Initial:* 300 mg twice daily. Dosage increased by 600 mg daily every wk over 2 to 4 wk, as needed, while dosage of other anticonvulsant reduced to complete withdrawal over 3 to 6 wk. *Usual:* 1,200 mg daily. *Maximum:* 2,400 mg daily.

**Children ages 4 to 16.** *Initial:* 4 to 5 mg/kg twice daily, increased by 10 mg/kg daily weekly as needed to maximum maintenance dosage while dosage of other anticonvulsant is reduced over 3 to 6 wk to complete withdrawal.

*Maintenance:* Based on weight as follows: 70 kg (154 lb)-1,500 to 2,100 mg/day; 60 to 65 kg (132 to 143 lb)-1,200 to 2,100 mg/day; 50 to 55 kg (110 to 121 lb)-1,200 to 1,800 mg/day; 45 kg (99 lb)-1,200 to 1,500 mg/day; 35 to 40 kg (77 to 88 lb)-900 to 1,500 mg/day; 25 to 30 kg (55 to 66 lb)-900 to 1,200 mg/day; and 20 kg (44 lb): 600 to 900 mg/day.

**DOSAGE ADJUSTMENT** Dosage adjustment may be required with concomitant use of strong CYP3A4 enzyme inducers or UGT inducers. For patients with creatinine clearance less than 30 ml/min, usual initial dosage reduced by 50%.

➤ *To treat partial seizures either adjunctively or as monotherapy*

## **XR TABLETS (OXTELLAR XR)**

**Adults and adolescents over age 16.** *Initial:* 600 mg once daily for 1 wk, increased in 600 mg a day increments weekly to reach target dose. *Maintenance:* 1,200 to 2,400 mg once daily. *Maximum:* 2,400 mg once daily.

**Children ages 6 to 17.** *Initial:* 8 to 10 mg/kg once daily, not to exceed initial dose of 600 mg in first wk, then increased in 8 to 10 mg/kg in once daily increments weekly, not to exceed dose of 600 mg daily. *Usual:* 900 mg daily for children weighing 20 to 29 kg (44 to 64 lb); 1,200 mg daily for those weighing 29.1 to 39 kg (65 to 86 lb);

1,800 mg daily for those weighing more than 39 kg (more than 86 lb). *Maximum:* 1,800 mg daily.

***DOSAGE ADJUSTMENT*** For patients taking concurrent strong CYP3A4 enzyme inducers or UGT enzyme inducers, initial dosage increased to 900 mg once daily for adults and 12 to 15 mg/kg for pediatric patients. For elderly patients and adults with a creatinine clearance less than 30 ml/min, initial dosage decreased by 50% with subsequent dosage increases made weekly in increments of 300 to 450 mg/day to achieve desired response.

## **Mechanism of Action**

May prevent or halt seizures by blocking or closing sodium channels in neuronal cell membrane. By preventing sodium from entering the cell, oxcarbazepine may slow nerve impulse transmission, thus decreasing the rate at which neurons fire.

## **Contraindications**

Hypersensitivity to oxcarbazepine, eslicarbazepine acetate, or their components

## **Interactions**

### **DRUGS**

*hormonal contraceptives:* Rendered less effective by immediate-release oxcarbazepine

*phenytoin:* Possibly increased phenytoin levels with increased risk of adverse reactions

*strong CYP3A4 or UGT inducers (carbamazepine, phenobarbital, phenytoin, rifampin):* Decreased oxcarbazepine levels with decreased effectiveness

## FOODS

*all food (XR tablets):* Increased risk of adverse effects

## ACTIVITIES

*alcohol use:* Possibly additive CNS depressant effects

## Adverse Reactions

**CNS:** Abnormal coordination or gait, agitation, amnesia, asthenia, ataxia, confusion, difficulty concentrating, dizziness, EEG abnormalities, emotional lability, fatigue, fever, headache, hypoesthesia, insomnia, language or speech problems, nervousness, psychomotor slowing, **seizures**, somnolence, **status epilepticus**, **suicidal ideation**, tremor, vertigo

**CV:** **AV block**, chest pain, **hypotension**, peripheral edema

**EENT:** Abnormal vision, diplopia, earache, ear infection, epistaxis, nystagmus, pharyngitis, rhinitis, sinusitis, taste perversion

**ENDO:** Hot flashes, hypothyroidism, syndrome of inappropriate antidiuretic hormone secretion

**GI:** Abdominal pain, anorexia, constipation, diarrhea, elevated liver or pancreatic enzymes, gastritis, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Frequent urination, UTI, vaginitis

**HEME:** **Agranulocytosis**, **aplastic anemia**, eosinophilia, **leukopenia**, **pancytopenia**, purpura

**MS:** Arthralgia, back pain, decreased bone mineral density, dysarthria, fractures, muscle weakness, osteoporosis (long-term therapy with immediate-release form)

**RESP:** Bronchitis, cough, respiratory tract infection

**SKIN:** Acne, acute generalized exanthematous pustulosis, diaphoresis, **erythema multiforme**, maculopapular rash,

rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other: Anaphylaxis, drug reaction with eosinophilia and systemic symptoms (DRESS), hyponatremia, lymphadenopathy, multiorgan hypersensitivity**

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org>.
- Drug may cause fetal harm such as an increased risk of congenital malformations such as oral clefts and ventricular septal defects.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential adverse reactions in the breastfed infant.

## Nursing Considerations

- Know that patient with allergic reaction to carbamazepine may have hypersensitivity to oxcarbazepine.
- Administer XR tablets to patients 1 hour before or 2 hours after a meal because adverse reactions are more likely to occur when taken with food.
- Monitor serum sodium level for signs of hyponatremia, especially during first 3 months. Know that elderly patients may be at higher risk for hyponatremia because of age-related reductions in creatinine clearance.
- Monitor therapeutic oxcarbazepine levels during initiation and titration, and expect to adjust dosage accordingly.

- Implement seizure precautions as needed, especially in patients who are pregnant, because physiological changes during pregnancy may cause oxcarbazepine levels to decrease gradually throughout pregnancy, increasing the risk of seizures. Patient should also be monitored closely throughout the postpartum period for adverse reactions, as the level of oxcarbazepine may return to normal after delivery. Aggravation of seizures can also occur in other patients, especially children. If seizures occur, expect oxcarbazepine to be discontinued.

**WARNING** Monitor patient's skin closely. If a reaction develops, notify prescriber at once because skin reactions caused by oxcarbazepine may be serious or life-threatening. Be aware that patients carrying the HLA-B\*1502 allele may be at increased risk for Stevens-Johnson syndrome or toxic epidermal necrolysis.

**WARNING** Watch closely for evidence of multiorgan hypersensitivity, such as arthralgia, asthenia, fever, hematologic abnormalities, hepatitis, hepatorenal syndrome, liver function abnormalities, lymphadenopathy, nephritis, oliguria, organ dysfunction, pruritus, and rash. If suspected, notify prescriber and expect to stop drug. Provide supportive care, as prescribed.

- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Monitor patient for CNS adverse reactions that may involve cognitive symptoms, coordination abnormalities, fatigue, and somnolence.
- Expect to discontinue oxcarbazepine gradually, as abrupt withdrawal may increase risk of seizure frequency and development of status epilepticus.

## **PATIENT TEACHING**

- Teach patient to shake suspension well and measure dose immediately afterward. Tell him to then withdraw prescribed amount using supplied oral dosing syringe. Instruct him to mix dose in a small glass of water just before taking it, or tell him that he can swallow drug directly from

syringe. Instruct him to close bottle and rinse syringe with warm water and let it dry thoroughly. Instruct patient to discard any unused oral suspension after 7 weeks of first opening the bottle.

- Instruct patient prescribed XR tablets not to break, chew, or crush tablets but to swallow whole.
- Inform patient that he may experience dizziness, double vision, and unsteady gait as well as other adverse CNS signs and symptoms. Caution him not to drive or perform any other hazardous activity if these effects occur.
- Instruct patient not to drink alcohol during oxcarbazepine therapy.
- Alert patient to possibility of hypersensitivity or serious skin reactions and importance of reporting them to prescriber.
- Review signs and symptoms of low sodium level with patient. Tell him to report signs and symptoms such as confusion, increase in severity of seizures, lack of energy, nausea, or tiredness to prescriber.
- Warn patient to notify prescriber immediately if he develops difficulty breathing or swallowing; fever; rash; swelling of face, eyes, lips, tongue; or other evidence of hypersensitivity because drug may have to be stopped and emergency medical care given.
- Alert woman of childbearing age that oxcarbazepine may render hormonal contraceptives ineffective. Urge patient to use an additional or a different contraceptive during oxcarbazepine therapy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns to prescriber at once.
- Urge female patient who becomes pregnant while taking oxcarbazepine to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy.
- Warn patient not to stop taking oxcarbazepine abruptly, as an increase in seizure activity may occur and possibly lead to status epilepticus.

## oxybutynin

### **Oxytrol, Oxytrol for Women**

# oxybutynin chloride

## Ditropan XL, Gelnique 10%

### Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Antispasmodic (urinary)

### Indications and Dosages

- *To treat overactive bladder with urge urinary frequency, incontinence or urgency*

#### E.R. TABLETS (DITROPAN XL)

**Adults.** *Initial:* 5 or 10 mg daily, adjusted by 5 mg/wk, as prescribed. *Maximum:* 30 mg daily.

#### TRANSDERMAL SYSTEM (OXYTROL)

**Adults.** System supplying 3.9 mg daily, applied twice weekly.

#### TOPICAL GEL (GELNIQUE 10%)

**Adults.** 1 sachet or one actuation of the metered dose pump applied once daily to dry, intact skin on the abdomen, upper arms, shoulders, or thighs.

- *To treat symptoms of detrusor muscle overactivity of bladder associated with a neurological condition such as spina bifida*

#### E.R. TABLETS (DITROPAN XL)

**Children age 6 and over.** *Initial:* 5 mg once daily, increased in 5 mg increments weekly, as needed.  
*Maximum:* 20 mg once daily.

Route	Onset	Peak	Duration
Gel	Unknown	Unknown	72 hr
P.O.	30-60 min	3-6 hr	6-10 hr
Transdermal	Unknown	24-48 hr	96 hr

## Mechanism of Action

Exerts antimuscarinic (atropine-like) and potent direct antispasmodic (papaverine-like) actions on smooth muscle in the bladder and decreases detrusor muscle contractions. The result is increased bladder capacity and a decreased urge to void.

## Contraindications

Angle-closure glaucoma, gastric retention, hypersensitivity to oxybutynin or its components, urine retention

## Interactions

### DRUGS

*anticholinergics:* Increased anticholinergic effects; possibly decreased absorption of some concomitantly administered drugs with major concern for those drugs with a narrow therapeutic index

*antimycotic agents (itraconazole, micronazole), ketoconazole, macrolide antibiotics (erythromycin, clarithromycin):* Increased plasma oxybutynin concentrations with increased risk of adverse reactions

*carbamazepine concurrently with dantrolene:* Increased risk of confusion, drowsiness, nystagmus, slurred speech, unsteadiness, and vomiting suggestive of carbamazepine toxicity

## ACTIVITIES

*alcohol use:* Increased CNS effects

## Adverse Reactions

**CNS:** **Abnormal behaviors**, **agitation**, asthenia, confusion, delirium, depression, dizziness, drowsiness, fatigue, hallucinations, headache, insomnia, memory impairment, nervousness, psychosis, restlessness, **seizures**, somnolence, thirst

**CV:** **Arrhythmias**, chest discomfort, edema, hypertension, **hypotension**, palpitations, peripheral edema, **QT-interval prolongation**, tachycardia, vasodilation

**EENT:** Abnormal or blurred vision; cycloplegia; dry eyes, mouth, nose, and throat; eye irritation; glaucoma; keratoconjunctivitis sicca; mydriasis; nasal congestion; nasopharyngitis; rhinitis; sinusitis

**ENDO:** Hot flashes, hyperglycemia, suppression of lactation

**GI:** Abdominal pain, anorexia, constipation, decreased GI motility, diarrhea, dysphagia, esophagitis, flatulence, gastroesophageal reflux, indigestion, nausea, vomiting

**GU:** Cystitis, dysuria, impotence, urinary hesitancy, urine retention, UTI

**MS:** Arthralgia, arthritis, back pain

**RESP:** **Asthma**, bronchitis, cough, dysphonia, upper respiratory tract infection

**SKIN:** Decreased sweating, dry skin, flushing, pruritus, rash, urticaria

**Other:** Anaphylaxis, angioedema, application-site reactions (anesthesia, dermatitis, erythema, irritation, papules, pruritus), flu-like symptoms, fungal infections, heatstroke

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use oxybutynin cautiously in patients with diarrhea because it may signal incomplete GI obstruction, especially in patients with colostomy or ileostomy. Also use cautiously in patients with dementia treated with cholinesterase inhibitors because drug may aggravate symptoms.
- Use cautiously in patients with GI disorders such as autonomic neuropathy, myasthenia gravis, or Parkinson's disease because drug may adversely affect these conditions. If exacerbation of symptoms occurs, notify prescriber and expect drug to be discontinued.
- Assess urinary symptoms before and after treatment.
- Make sure patient swallows E.R. tablets whole and doesn't chew, crush, or divide them. Expect to see portions of drug in stool.
- Apply transdermal system to dry, intact skin of abdomen, buttock, or hip; avoid using same site for at least 7 days by rotating sites.
- Apply gel form to dry, intact skin on patient's abdomen, shoulders, thighs, or upper arms. Rotate application sites.

**WARNING** Monitor patient for angioedema of the face, lips, tongue, and/or larynx, even after just the first dose. If present, notify prescriber, stop oxybutynin therapy, as ordered, and provide emergency supportive care.

**WARNING** Watch for adverse cardiovascular reactions in patients with arrhythmias, coronary artery disease, heart failure, or hypertension because drug's antimuscarinic effects may increase their risk.

- Keep in mind that decreased GI motility can cause adynamic ileus; assess for abdominal pain and ileus. Also use with caution in patients who have intestinal atony or ulcerative colitis, because of decreased gastrointestinal motility.
- Be aware that drug may aggravate benign prostatic hyperplasia, gastroesophageal reflux disease, and hyperthyroidism.
- Monitor patient for anticholinergic CNS effects, such as agitation, confusion, hallucinations, and somnolence, especially in the first few months of therapy or when dosage is increased. If such effects occur, notify prescriber and expect dosage to be reduced or drug discontinued.

## **PATIENT TEACHING**

- Instruct patient to take oxybutynin on an empty stomach. If adverse GI reactions develop, suggest taking drug with food or milk.
- Advise patient to swallow E.R. tablets whole and not to break, chew, or crush them.
- Instruct patient how to apply gel transdermal system. Tell her to apply to clean, dry skin, avoiding areas that have been recently shaved or have open sores or rashes. Remind patient to wash hands after handling product.
- Warn patient that gel is flammable and that she should avoid open fire or smoking until gel has dried. Also tell patient to avoid bathing, exercising, showering, swimming, or immersing application site in water for 1 hour after application and to cover site with clothing once gel has dried.
- Warn of possible decreased alertness, and advise patient against performing hazardous activities until drug's CNS effects are known.

- Caution patient to avoid excessive sun exposure and strenuous exercise because of increased risk of heatstroke.
- Urge patient to avoid alcohol during therapy.
- Instruct patient to seek immediate emergency care if he experiences swelling of his face, lips, throat, or tongue, or if he has difficulty breathing.

## oxycodone

**Xtampza ER**

## oxycodone hydrochloride

**Oxaydo, OxyContin, Roxybond,  
Roxicodone, Supeudol (CAN)**

### **Class, Category, and Schedule**

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

### **Indications and Dosages**

- *To relieve pain severe enough to require opioid treatment and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated*

## **ORAL SOLUTION (ROXICODONE), TABLETS (OXAYDO, ROXYBOND, ROXICODONE)**

**Adults.** 5 to 15 mg every 4 to 6 hr.

## **SUPPOSITORY (SUPEUDOL)**

**Adults.** 1 suppository three to four times daily.

## **TABLETS (SUPEUDOL)**

**Adults.** 5 to 10 mg every 6 hr.

- *To manage moderate to severe pain when a continuous around-the-clock opioid analgesic is needed for an extended period of time*

## **E.R. TABLETS (OXYCONTIN)**

**Adults who haven't received opioids before; adults converting from other opioids.** *Initial:* 10 mg every 12 hr, increased every 1 to 2 days, as needed to achieve desired pain control.

**Adults converting from other oral oxycodone formulations.** Half the 24-hr oxycodone dose every 12 hr.

**Adults converting from methadone.** Highly individualized.

**Adults and children age 11 and over converting from fentanyl transdermal patch.** Highly individualized.

*Usual:* 10 mg oxycodone for each 25 mcg/hr of fentanyl patch dosage every 12 hr, beginning 18 hr after removing patch.

**Children age 11 and over who are already receiving opioids for at least 5 consecutive days and requiring at least 20 mg of oxycodone daily.** *Initial:* Highly individualized and based on the type of opioid taken prior to oxycodone dosing. For example for conversion from

hydrocodone dose would be 20 mg every 12 hr, increased every 1 to 2 days, as needed.

## **E.R. CAPSULES (XTAMPZA ER)**

**Adults who are opioid-naïve, not opioid tolerant, or converting from other opioids.** 9 mg every 12 hr with food, increased as needed with dose adjusted to obtain balance between management of pain and opioid-related adverse reactions. *Maximum:* 288 mg daily in divided doses.

**Adults converting from fentanyl transdermal patch.** Highly individualized. *Usual:* 9 mg oxycodone for each 25 mcg/hr of fentanyl patch dosage every 12 hr, beginning 18 hr after removing patch.

**Adults converting from other oral oxycodone formulations.** Highly individualized. *Usual:* Half the 24-hr oxycodone dose every 12 hr.

**Adults converting from methadone.** Highly individualized.

**DOSAGE ADJUSTMENT** For elderly patients, patients with hepatic impairment, or patients currently taking a CNS depressant, one-third to one-half the usual starting dose and then adjusted, as needed.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	10-15 min	1 hr	3-4 hr
P.R.	15-30 min	Unknown	Unknown

## **Mechanism of Action**

Alters perception of and emotional response to pain at spinal cord and higher levels of CNS by blocking release of inhibitory neurotransmitters, such as acetylcholine and gamma-aminobutyric acid.

# Contraindications

Acute or severe bronchial asthma or hypercarbia in an unmonitored setting or in the absence of resuscitative equipment, gastrointestinal obstruction, hypersensitivity to oxycodone or its components, paralytic ileus, significant respiratory depression

# Interactions

## DRUGS

*5-HT<sub>3</sub> receptor antagonists, certain muscle relaxants (cyclobenzaprine, metaxalone), drugs that affect the serotonin neurotransmitter system (mirtazapine, tramadol, trazodone), MAO inhibitors including I.V. methylene blue and linezolid, selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome

*anticholinergics:* Possibly severe constipation and ileus; increased risk of urinary retention

*anxiolytics, antipsychotics, benzodiazepines, generalized anesthetics, muscle relaxants, other CNS depressants, other opioids, sedating antihistamines, tranquilizers, tricyclic antidepressants:* Increased risk of severe respiratory depression and significant sedation and somnolence

*CYP3A4 inducers such as carbamazepine, phenytoin, rifampin:* Possibly decreased oxycodone levels making it less effective

*CYP3A4 inhibitors such as azole-antifungal drugs, macrolide antibiotics, and protease inhibitors:* Possibly increased plasma oxycodone levels and prolonged opioid effects with possible overdose effects

*diuretics*: Reduced effectiveness of diuretics  
*MAO inhibitors such as linezolid, phenelzine, tranylcypromine*: Increased risk of serotonin syndrome; increased risk of opioid toxicity  
*mixed agonist/antagonist and partial agonist opioid analgesics such as buprenorphine, butorphanol, nalbuphine, pentazocine*: Decreased analgesic effect of oxycodone and/or precipitation of withdrawal symptoms  
*muscle relaxants such as cyclobenzaprine, metaxalone*: Enhanced neuromuscular blocking action increasing degree of respiratory depression; increased risk of serotonin syndrome

## ACTIVITIES

*alcohol use*: Additive CNS and respiratory depressive effects that may become severe

## Adverse Reactions

**CNS**: Abnormal dreams, anxiety, asthenia, chills, dizziness, drowsiness, euphoria, excitation, headache, insomnia, nervousness, sedation, **seizures**, somnolence, syncope, twitching

**CV**: **Bradycardia**, chest pain, **hypotension**, orthostatic hypotension, palpitations

**EENT**: Blurred vision, **choking** or difficulty swallowing tablets (OxyContin), dry eyes or mouth, lens opacities, miosis

**ENDO**: **Adrenal insufficiency** (rare), syndrome of inappropriate antidiuretic hormone secretion

**GI**: Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes, gastritis, hiccups, ileus, nausea, vomiting

**GU:** Amenorrhea, decreased libido, erectile dysfunction, impotence, infertility, lack of menstruation, oliguria, urinary hesitancy, urine retention

**RESP:** Dyspnea, **respiratory depression**

**SKIN:** Diaphoresis, pruritus, rash

**Other:** **Anaphylaxis**, drug tolerance, **hyponatremia**, physical and psychological dependence, withdrawal symptoms

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the neonate. Monitor neonate closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

- If breastfeeding occurs, monitor infant for excess sedation and respiratory depression.

## REPRODUCTION

- Chronic use of opioids may reduce fertility.

## Nursing Considerations

- Be aware that excessive use of opioids like oxycodone may lead to abuse, addiction, misuse, overdose, and possibly death. For this reason, a Risk Evaluation and Mitigation Strategy (REMS) is required for oxycodone to be prescribed. Monitor patient's intake of drug closely and for evidence of physical dependence.
- Know that chronic maternal use of oxycodone during pregnancy can result in NOWS, which may be life-threatening if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to opioid drugs like oxycodone for a prolonged period while in utero.
- Use extreme caution when administering oxycodone to patients with conditions accompanied by hypoxia or decreased respiratory reserve such as asthma, COPD, or cor pulmonale. This is because even with usual therapeutic dosages, oxycodone may decrease respiratory drive while simultaneously increasing airway resistance to the point of apnea. Monitor patient's respiratory status closely, especially in cachectic, debilitated, and elderly patients and in patients with chronic pulmonary disease. Respiratory depression may occur at any time, but it is most likely to occur during the initiation of therapy or following a dose increase. Have resuscitative equipment nearby.
- Use oxycodone with extreme caution in patients who may be at risk for carbon dioxide retention (e.g., those with increased intracranial pressure or brain tumors). Monitor for signs of sedation and respiratory depression, especially when initiating therapy. Oxycodone may reduce respiratory drive, and the resultant carbon dioxide retention can further increase intracranial pressure. Also know that opioids like oxycodone may obscure signs and symptoms in a patient with a head injury.

**WARNING** Be aware that oxycodone should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of

oxycodone to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

- Assess patient's pain level regularly, and give drug as prescribed before pain becomes severe.
- Be careful to have patient swallow one controlled-release tablet (OxyContin) at a time, with enough water to ensure complete swallowing immediately after the patient places the tablet in his mouth; otherwise, choking on tablets or difficulty swallowing the tablets may occur due to the swelling and hydrogelling property of the tablet if left in the mouth too long.
- Be prepared to adjust dosage for patient who hasn't previously received opioids, as prescribed, until he can tolerate drug effects.
- Monitor patient's blood pressure closely, especially when initiating oxycodone therapy and when titrating the dose, because oxycodone may cause severe hypotension and syncope in ambulatory patients due to its vasodilatory effects. Risk of hypotension is greater in patients who already have been compromised by a reduced blood volume or concurrent administration of certain CNS depressant drugs, such as general anesthetics and phenothiazines.
- Assess patient for possible paradoxical excitation during dosage titration.
- Assess patient for abdominal pain because oxycodone may mask underlying GI disorders.

**WARNING** Know that many drugs may interact with opioids like oxycodone to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If confirmed, expect to administer corticosteroids and wean patient off oxycodone, if possible.
- Monitor patients with seizure disorders closely because oxycodone may induce or aggravate seizures.

**WARNING** Be aware that oxycodone given concomitantly with CYP3A4 inhibitors (or if CYP3A4 inducers are discontinued) can result in a fatal overdose of oxycodone.

**WARNING** Be aware that abuse of crushed controlled-release tablets poses a hazard of overdose and death. If you suspect abuse and determine that patient also is abusing alcohol or illicit substances, notify prescriber immediately because risk of overdose and death is increased. If you suspect parenteral abuse, be aware that tablet excipients, especially talc, may result in endocarditis, infection, local tissue necrosis, pulmonary granulomas, and valvular heart injury.

- Know that oxycodone therapy should not be stopped abruptly in a physically dependent patient.

## **PATIENT TEACHING**

**WARNING** Strongly warn patient to swallow oxycodone tablets whole and not to break, chew, or crush them because taking broken, chewed, or crushed tablets leads to rapid release and absorption of a potentially fatal dose.

- Remind patient that Xtampza ER capsules must be taken with food. Tell patient to consume about the same amount of food for every dose in order to maintain consistent blood levels of the drug.

- Instruct patient not to take oxycodone more often than prescribed and not to take it longer than absolutely needed because excessive or prolonged use can lead to abuse, addiction, misuse, overdose, and possibly death. Also warn patient not to stop abruptly after long-term use.
- Caution patient prescribed controlled-release tablets to take one tablet at a time; not to presoak, lick, or otherwise wet the tablet prior to placing in his mouth; and to take each tablet with enough water to ensure complete swallowing of tablet.
- Advise patient prescribed suppository form to store drug in refrigerator for 30 minutes or run under cold water if it is too soft to administer.

**WARNING** Warn patient not to consume alcohol or take a benzodiazepine without prescriber knowledge, as severe respiratory depression can occur and may lead to death.

- Caution patient to avoid hazardous activities such as driving during oxycodone therapy.
- Tell patient to notify prescriber about signs of possible toxicity or hypersensitivity, such as excessive light-headedness, extreme dizziness, itching, swelling, and trouble breathing.
- Warn patient to keep drug out of reach of children because ingestion of the drug by a child can be fatal.
- Inform patient that long-term use of opioids like oxycodone may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms to prescriber.
- Caution pregnant patient not to increase dosage or take drug for a prolonged period, as adverse effects can cause infant to experience life-threatening withdrawal when born.
- Instruct patient to notify all prescribers of opioid use.
- Instruct patient to dispose of unused drug by flushing down the toilet, if a drug take-back option is not readily available.

**oxymorphone hydrochloride**

# Numorphan, Opana, Opana ER

## Class, Category, and Schedule

*Pharmacologic class:* Opioid

*Therapeutic class:* Opioid analgesic

*Controlled substance schedule:* II

## Indications and Dosages

- *To relieve pain severe enough to require opioid treatment and for which alternative treatment options such as nonopioid analgesics or opioid combination products are inadequate or not tolerated.*

### **TABLETS (OPANA)**

**Adults receiving an opioid for first time.** *Initial:* 10 to 20 mg every 4 to 6 hr, as needed with dosage adjusted based on patient response.

**Adults converting from parenteral oxymorphone.**

*Initial:* 10 times the patient's total daily parenteral oxymorphone dose divided by 4 or 6 to provide four or six equally divided doses every 4 to 6 hr.

**Adults converting from other oral opioids.** Highly individualized.

***DOSAGE ADJUSTMENT*** For patients with mild hepatic impairment or who have a creatinine clearance less than 50 ml/min or for opioid-naïve patients over the age of 65, initial dosage started at 5 mg.

### **E.R. TABLETS (OPANA ER)**

**Adults who are receiving an opioid for first time or are opioid nontolerant.** 5 mg every 12 hr, increased every 3 to 7 days in increments of 5 to 10 mg every 12 hr.

**Adults converting from immediate-release oxymorphone to extended-release form.** Half the patient's total daily oral immediate-release dosage every 12 hr.

**Adults converting from parenteral oxymorphone.**

*Initial:* 10 times the patient's total daily parenteral oxymorphone dose divided by 2 to provide two equally divided doses every 12 hr.

**Adults converting from other oral opioids.** Highly individualized.

***DOSAGE ADJUSTMENT*** For elderly patients, patients with mild hepatic impairment, or patients with renal impairment who are opioid-naïve, titration done slowly, as needed. For patients on prior opioid therapy with hepatic or renal impairment, initial dosage reduced by 50% and titrated slowly thereafter, as needed.

➤ *To provide support for anesthesia and use as preoperative medication; to relieve anxiety in patients with dyspnea from pulmonary edema caused by acute left ventricular dysfunction*

## **I.V. INJECTION (NUMORPHAN)**

**Adults.** *Initial:* 0.5 mg, repeated every 3 to 6 hr, as needed.

## **I.M. OR SUBCUTANEOUS INJECTION (NUMORPHAN)**

**Adults.** *Initial:* 1 to 1.5 mg, repeated every 4 to 6 hr, as needed.

## **SUPPOSITORIES (NUMORPHAN)**

**Adults.** 5 mg every 4 to 6 hr, as needed.

➤ *To relieve obstetric pain during labor*

## **I.M. INJECTION (NUMORPHAN)**

**Adults.** 0.5 to 1 mg as a single dose.

**DOSAGE ADJUSTMENT** For debilitated or elderly patients and patients with severe liver disease, dosage reduced.

Route	Onset	Peak	Duration
I.V.	5–10 min	15–30 min	3–4 hr
I.M.	10–15 min	30–90 min	3–6 hr
SubQ	10–20 min	30–90 min	3–6 hr
P.R.	15–30 min	2 hr	3–6 hr

## **Mechanism of Action**

Alters perception of and emotional response to pain at spinal cord and higher levels of CNS by blocking release of inhibitory neurotransmitters, such as acetylcholine and gamma-aminobutyric acid.

## **Contraindications**

Acute or severe bronchial asthma in an unmonitored setting or in the absence of resuscitative equipment; gastrointestinal obstruction, including paralytic ileus; hypersensitivity to oxymorphone or its components; moderate or severe hepatic impairment; significant respiratory depression

## **Interactions**

### **DRUGS**

*5-HT<sub>3</sub> receptor antagonists, certain muscle relaxants (cyclobenzaprine, metaxalone), drugs that affect the serotonin neurotransmitter system (mirtazapine, tramadol, trazodone), MAO inhibitors such as I.V. methylene blue or linezolid, selective serotonin reuptake inhibitors, serotonin and norepinephrine reuptake inhibitors, tricyclic antidepressants, triptans:* Increased risk of serotonin syndrome  
*anticholinergics:* Increased risk of urine retention, severe constipation  
*anxiolytics, antipsychotics, benzodiazepines, general anesthetics, muscle relaxants, other CNS depressants, other opioids, sedating antihistamines, tranquilizers:* Increased risk of severe respiratory depression and significant sedation and somnolence  
*diuretics:* Decreased effectiveness of diuretics  
*MAO inhibitors:* Increased risk of serotonin syndrome; increased risk of opioid toxicity  
*mixed agonist/antagonist and partial agonist opioid analgesics such as buprenorphine, butorphanol, nalbuphine, pentazocine:* Possibly reduced analgesic effect of oxymorphone  
*muscle relaxants:* Enhanced neuromuscular blocking acting increasing degree of respiratory depression

## **ACTIVITIES**

*alcohol use:* Additive CNS and respiratory depressant effects which could be severe

## **Adverse Reactions**

**CNS:** Agitation, asthenia, CNS depression, confusion, delusions, depersonalization, dizziness, drowsiness, euphoria, fatigue, hallucinations, headache, insomnia, light-

headedness, nervousness, nightmares, restlessness, **seizures**, somnolence, tiredness, tremor, weakness

**CV:** **Bradycardia**, hypertension, **hypotension**, palpitations, tachycardia

**EENT:** Blurred vision, diplopia, dry mouth, **laryngeal edema**, **laryngospasm**, miosis, tinnitus

**ENDO:** **Adrenal insufficiency**

**GI:** Abdominal cramps or pain, anorexia, biliary colic, constipation, elevated serum amylase level, **hepatotoxicity**, ileus, nausea, spasm of the sphincter of Oddi (E.R. tablets), vomiting

**GU:** Decreased urine output, decreased libido, dysuria, erectile dysfunction, impotence, infertility, lack of menstruation, urinary frequency and hesitancy, urine retention

**MS:** Muscle rigidity (with large doses), uncontrolled muscle movements

**RESP:** **Apnea**, **atelectasis**, **bradypnea**, **bronchospasm**, dyspnea, irregular breathing, **irregular breathing**, **respiratory depression**, wheezing

**SKIN:** Dermatitis, diaphoresis, erythema, flushing of face, pruritus, urticaria

**Other:** **Angioedema**; injection-site burning, pain, redness, and swelling; psychological and physical dependence

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Prolonged use of drug during pregnancy can result in Neonatal Opioid Withdrawal Syndrome, which may be life-threatening if not recognized and treated.
- Avoid prolonged use during pregnancy. Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LABOR & DELIVERY**

- Drug is not recommended for use in pregnant women immediately before or during labor. Opioids may alter length of time of labor.
- Opioids cross the placental barrier and may produce respiratory depression and psycho-physiologic effects in the neonate. Monitor neonate closely for signs of excess sedation and respiratory depression.
- An opioid antagonist, such as naloxone, must be available at the time of delivery in the event it is needed to reverse opioid-induced respiratory depression in the neonate.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, monitor infant for excess sedation and respiratory depression.

## **REPRODUCTION**

- Chronic use of opioids may reduce fertility.

## **Nursing Considerations**

- Be aware that excessive use of opioids like oxymorphone may lead to abuse, addiction, misuse, overdose, and possibly death. Monitor patient's intake of drug closely and watch for evidence of physical dependence. Know that drug use now requires a Risk Evaluation and Mitigation Strategy (REMS) for a prescription.
- Know that chronic maternal use of oxymorphone during pregnancy can result in NOWS, which may be life-threatening if not recognized and treated appropriately. NOWS occurs when a newborn has been exposed to opioid drugs like oxymorphone for a prolonged period while in utero.
- Use extreme caution when administering oxymorphone to patients with conditions accompanied by decreased respiratory reserve or hypoxia, such as asthma, COPD, or cor pulmonale. This is because oxymorphone, even

with usual therapeutic dosages, may decrease respiratory drive while simultaneously increasing airway resistance to the point of apnea.

- Use oxymorphone with extreme caution in patients who may be at risk for carbon dioxide retention (e.g., those with brain tumors or increased intracranial pressure). Monitor for signs of respiratory depression and sedation, especially when initiating therapy. Oxymorphone may reduce respiratory drive, and the resultant carbon dioxide retention can further increase intracranial pressure. Also know that opioids like oxymorphone may obscure signs and symptoms in a patient with a head injury.
- Use cautiously in patients with biliary tract disease because drug may cause spasm of sphincter of Oddi; mild hepatic impairment because drug is metabolized in liver; and impaired renal function because drug is excreted by kidneys.
- Use cautiously in patients receiving mixed agonist-antagonist opioid analgesics because these drugs may reduce analgesic effect of oxymorphone or may cause withdrawal symptoms.
- Use cautiously in elderly patients because plasma oxymorphone levels in the elderly are higher than in younger patients.
- Know that oral hydromorphone shouldn't be used "as needed" or for first 24 hours after surgery in patients not already taking opioids because of the risk of oversedation and respiratory depression.
- Taper dosage, as ordered, before stopping therapy to prevent withdrawal in physically dependent patients.

**WARNING** Monitor patient's respiratory status closely for respiratory depression, especially in cachectic, debilitated, or elderly patients; when initiating or titrating dosages; or when other drugs that depress respiration are given together. Have resuscitative equipment nearby. Report respiratory depression immediately, because severe respiratory depression may occur. Be prepared to provide supportive care.

- Monitor patient's blood pressure closely, especially when initiating oxymorphone therapy and when titrating the dose because oxymorphone may cause severe hypotension and syncope in ambulatory patients due to its vasodilatory effects. Risk of hypotension is greatest in patients who already have been compromised by a reduced blood volume or concurrent administration of certain CNS depressant drugs, such as general anesthetics and phenothiazines.

**WARNING** Know that many drugs may interact with opioids like oxymorphone to cause serotonin syndrome. Monitor patient closely for signs and symptoms such as agitation, diaphoresis, diarrhea, fever, hallucinations, labile blood pressure, muscle twitching or stiffness, nausea, shakiness, shivering, tachycardia, trouble with coordination, or vomiting. Notify prescriber at once because serotonin syndrome may be life-threatening. Be prepared to discontinue drug, if possible and ordered, and provide supportive care.

- Monitor patient for adrenal insufficiency. Although rare, it can be life-threatening. Monitor patient for anorexia, dizziness, fatigue, hypotension, nausea, vomiting, or weakness. Notify prescriber if adrenal insufficiency is suspected and expect diagnostic testing to be done. If confirmed, expect to administer corticosteroids and wean patient off oxymorphone, if possible.
- Monitor patient for signs of excessive opioid-related adverse reactions. If present, notify prescriber and expect next dose to be reduced.
- Monitor bowel and urinary status; constipation may be so severe it causes ileus.
- Offer fluids to relieve dry mouth.

**WARNING** Be aware that oxymorphone should only be used concomitantly with benzodiazepine therapy in patients for whom other treatment options are inadequate. If prescribed together, expect dosing and duration of oxymorphone to be limited. Monitor patient closely for signs and symptoms of a decrease in consciousness, including coma, profound sedation, and significant respiratory depression. Notify prescriber immediately and provide emergency supportive care, as death may occur.

## **PATIENT TEACHING**

- Instruct patient to take oxymorphone exactly as prescribed and not to stop abruptly; warn that drug can cause abuse, misuse, overdose, physical dependence, and possibly death.
- Emphasize importance of taking drug before pain becomes severe.
- Instruct patient prescribed oxymorphone in tablet form to take it on an empty stomach.
- Instruct patient to store suppositories in refrigerator.
- Encourage patient to increase fluid and fiber intake during therapy to prevent constipation.
- Emphasize need to avoid alcohol, benzodiazepine therapy, and CNS depressants during therapy because of risk of severe life-threatening adverse reactions.
- Caution patient to avoid potentially hazardous activities until drug's CNS effects are known.
- Advise female patient to notify prescriber about known or suspected pregnancy because if fetus is exposed to opioids for a prolonged period, the baby may experience withdrawal when born.
- Warn patient to keep drug out of the reach of children, as accidental ingestion may be fatal.
- Inform patient that long-term use of opioids like oxymorphone may decrease sex hormone levels, causing decreased libido, erectile dysfunction, impotence, infertility, or lack of menstruation. Encourage patient to report any symptoms to prescriber.
- Instruct patient to notify all prescribers of opioid use.
- Instruct patient to dispose of unused drug by flushing down the toilet, if a drug take-back option is not readily available.

# P

## paliperidone

**Invega**

## paliperidone palmitate

**Invega Sustenna, Invega Trinza**

### Class and Category

*Pharmacologic class:* Benzisoxazole derivative

*Therapeutic class:* Antipsychotic (atypical)

### Indications and Dosages

➤ *To treat schizophrenia*

#### **E.R. TABLETS (INVEGA)**

**Adults.** *Initial:* 6 mg once daily in the morning; then increased or decreased in increments of 3 mg daily every 6 or more days, as needed. *Maximum:* 12 mg daily.

**Adolescents 12 to 17.** *Initial:* 3 mg once daily; then increased in increments of 3 mg daily every 6 or more days, as needed. *Maximum:* 12 mg once daily for adolescents weighing 51 kg (112 lb) or more and 6 mg once daily for adolescents weighing less than 51 kg (112 lb).

## **I.M. INJECTION (INVEGA SUSTENNA)**

**Adults.** *Initial:* 234 mg on day 1 and 156 mg 1 wk later. *Maintenance:* 39 to 234 mg monthly. Maintenance dosage decreased or increased monthly according to patient's response and tolerance. *Maximum:* 234 mg monthly.

## **I.M. INJECTION (INVEGA TRINZA)**

**Adults who have been adequately treated with Invega Sustenna for at least 4 mo.** *Initial:* 273 mg if last monthly Sustenna dose was 78 mg; 410 mg if last monthly Sustenna dose was 117 mg; 546 mg if last monthly Sustenna dose was 156 mg; or 819 mg if last monthly Sustenna dose was 234 mg, administered within 7 days before or after next monthly Sustenna dose would have been given with dosage adjustment made thereafter every 3 mo, as needed.

*Maintenance:* 273 to 819 mg every 3 mo. *Maximum:* 819 mg every 3 mo.

➤ *To treat schizoaffective disorder*

## **E.R. TABLETS (INVEGA)**

**Adults.** *Initial:* 6 mg once daily; then increased or decreased in increments of 3 mg daily every 5 or more days, as needed. *Maximum:* 12 mg daily.

## **I.M. INJECTION (INVEGA SUSTENNA)**

**Adults.** *Initial:* 234 mg on day 1 and 156 mg 1 wk later. *Maintenance:* 78 to 234 mg monthly. Maintenance dosage decreased or increased monthly according to patient's response and tolerance. *Maximum:* 234 mg monthly.

**DOSAGE ADJUSTMENT** For patients taking E.R. tablets with mild renal impairment (creatinine clearance 50 to 79 ml/min), initial dosage decreased to 3 mg daily then increased to maximum dosage 6 mg daily; moderate to

severe renal impairment (creatinine clearance 10 ml/min to less than 50 ml/min), initial dose decreased to 1.5 mg daily, then increased to maximum dosage of 3 mg daily. For patient receiving Invega Sustenna with mild renal impairment (creatinine clearance equal to or greater than 50 ml/min but less than 80 ml/min), initial dosage decreased to 156 mg on day 1 and second dose given 1 wk later decreased to 117 mg, followed by 78 mg monthly. For patient receiving a strong CYP3A4 inducer such as carbamazepine, rifampin, or St. John's wort, these drugs should be avoided if patient is to receive Invega Sustenna or if use of these drugs must continue, extended release tablets (Invega) should be used instead of Invega Sustenna. For patient receiving Invega Trinza with mild renal impairment (creatinine clearance greater than 50 ml/min to less than 80 ml/min), patient stabilized using Invega Sustenna then transitioned to Invega Trinza. Invega Trinza is not recommended in patients with moderate or severe renal impairment (creatinine clearance less than 50 ml/min).

Route	Onset	Peak	Duration
P.O.	Unknown	24 hr	Unknown
I.M.	1 day	13 days	126 days

## Mechanism of Action

The main active metabolite of risperidone, paliperidone selectively blocks serotonin and dopamine receptors in mesocortical tract of CNS to suppress psychotic symptoms.

## Contraindications

*For all forms:* History of cardiac arrhythmias, congenital heart disease, or congenital long-QT syndrome;

hypersensitivity to paliperidone, risperidone, or its components

*For oral form:* Preexisting severe gastrointestinal narrowing

## Interactions

### DRUGS

*alpha agonists, alpha blockers, angiotensin-converting enzyme (ACE) inhibitors, angiotensin II receptor blockers (ARBs), beta blockers, calcium channel blockers, diuretics including thiazide, nitrates, vasodilators:* Increased risk of hypotension, including orthostatic  
*antiarrhythmics of class IA (such as quinidine, procainamide) and class III (such as amiodarone, sotalol), antibiotics (such as gatifloxacin, moxifloxacin), antipsychotics (such as chlorpromazine, thioridazine):* Increased risk of QT-interval prolongation  
*bromocriptine, levodopa and other dopamine agonists, pergolide:* Possibly antagonized effects of these drugs  
*CNS depressants:* Additive CNS depression  
*CYP3A4 and P-gp strong inducers (carbamazepine, rifampin, St. John's wort):* Decreased plasma paliperidone level and effectiveness  
*paroxetine:* Possible increased blood paliperidone level

### ACTIVITIES

*alcohol use:* CNS depression

## Adverse Reactions

**CNS:** Agitation, akathisia, anxiety, asthenia, bradykinesia, cogwheel rigidity, **CVA**, dizziness, drooling, dyskinesia,

dystonia, extrapyramidal disorder, fatigue, fever, headache, hyperkinesia, hypertonia, insomnia, lethargy, **neuroleptic malignant syndrome**, nightmares, nuchal rigidity, Parkinsonism, psychomotor hyperactivity, restlessness, **seizures**, somnambulism, somnolence, syncope, tardive dyskinesia, transient ischemic attack, tremor, vertigo

**CV:** **Bradycardia**, bundle branch block, elevated cholesterol and triglyceride level, first-degree heart block, hypertension, ischemia, orthostatic hypotension, palpitations, peripheral edema, **prolonged QT interval**, tachycardia, **venous thrombosis**

**EENT:** Blurred vision, dry mouth, eye movement disorder, nasal congestion, nasopharyngitis, oromandibular dystonia, pharyngolaryngeal pain, rhinitis, salivary hypersecretion, swollen tongue, toothache

**ENDO:** Breast engorgement, pain, or tenderness; gynecomastia; hyperglycemia; hyperprolactinemia

**GI:** Abdominal discomfort, constipation, diarrhea, dyspepsia, flatulence, ileus, nausea, **small intestinal obstruction**, upper abdominal pain, vomiting

**GU:** Erectile dysfunction, menstrual abnormalities, priapism, urinary incontinence or retention, UTI

**HEME:** **Agranulocytosis, leukopenia, neutropenia, thrombocytopenia, thrombotic thrombocytopenic purpura**

**MS:** Arthralgia; back or limb pain; dysarthria; joint stiffness; muscle rigidity, spasms, tightness, or twitching; myalgia; torticollis, trismus

**RESP:** Cough, dyspnea, upper respiratory tract infection

**SKIN:** Drug eruption, pruritus, rash, urticaria

**Other:** **Anaphylaxis, angioedema**, injection-site reactions, weight gain

## **Childbearing Considerations**

## **PREGNANCY**

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- Drug may cause fetal harm.
- Exposure to drug during the third trimester of pregnancy increases the risk for extrapyramidal and/or withdrawal symptoms following delivery.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, advise mothers to monitor their infants for excess sedation, extrapyramidal symptoms (tremors and abnormal muscle movements), failure to thrive, and jitteriness.

## **REPRODUCTION**

Know that women of childbearing age may experience a decrease in fertility during drug therapy that is reversible when drug is discontinued.

## **Nursing Considerations**

- Keep in mind paliperidone shouldn't be used to treat dementia-related psychosis in the elderly because of an increased mortality risk. Parenteral paliperidone is not recommended for patients with moderate to severe renal impairment.
- Know that drug shouldn't be given if patient has a condition that severely narrows GI tract because tablet doesn't change shape as it passes and could cause blockage.
- Use paliperidone cautiously in patients with cardiovascular disease, because drug may cause orthostatic hypotension. Also use cautiously in

patients with Lewy bodies, because these patients are more sensitive to antipsychotic drugs. Monitor patient for increased sensitivity manifested as confusion, extrapyramidal symptoms, neuroleptic malignant syndrome clinical features, postural instability with frequent falls, and obtundation.

- Be aware that the long-acting preparation (Invega Sustenna) should be initiated only after patient has been established with oral paliperidone or oral risperidone therapy. Also know that Invega Trinza should not be given until patient has received Invega Sustenna for at least 4 months.
- Administer parenteral paliperidone slowly as a deep intramuscular injection. The first two injections should be administered in the deltoid muscle; thereafter, the injection may be administered in the deltoid or gluteal muscle. Use a 1.5-inch 22G needle for gluteal administration or, if the patient weighs more than 200 pounds, for injecting drug into the deltoid muscle. If patient weighs less than 200 pounds, use a 1-inch 23G needle when administering drug in the deltoid muscle.
- Know that if the due date for the parenteral dose is missed, the recommended reinitiation depends on the length of time that has elapsed since the patient's last injection. To avoid missing a dose, the prescriber may order the parenteral dose to be given up to 7 days before or after the due date.
- Be aware that when a patient who has been taking a long-acting injectable antipsychotic consistently is now switching to the long-lasting 1 month preparation of paliperidone, the first dose of paliperidone is given in place of the next scheduled injection of the other medication. Parenteral long-acting 1 month preparation of paliperidone therapy is then continued at monthly intervals. The 1-week initiation dosing is not required.
- Know that the patient may switch from the 3-month long-acting paliperidone preparation to the 1 month preparation or to E.R. tablets. When doing so the new preparation is begun 3 months after the last dose of the long-acting 3-month preparation and dosage adjustment made according to the new preparation guidelines.

**WARNING** Notify prescriber immediately and expect to stop drug if patient shows signs of neuroleptic malignant syndrome (altered mental status, autonomic instability, hyperpyrexia, muscle rigidity). Patients at risk for developing neuroleptic malignant syndrome are patients with dementia with Lewy bodies or Parkinson's disease because these patients can experience increased sensitivity to paliperidone.

- Monitor patient for involuntary, dyskinetic movements. Notify prescriber if present, and expect to stop therapy. In some cases, therapy may have to continue despite tardive dyskinesia.
- Monitor blood glucose level because drug increases risk of hyperglycemia and possible hyperosmolar coma or ketoacidosis.
- Keep in mind dosage adjustments of paliperidone may be needed when carbamazepine therapy is started or discontinued because of carbamazepine's interaction with paliperidone.
- Check CBC often during first few months of therapy, especially if patient has low WBC count or history of drug-induced leukopenia or neutropenia. If WBC count declines, and especially if neutrophil count goes below  $1,000/\text{mm}^3$ , expect to stop drug. If neutropenia is significant, also watch for evidence of infection and provide appropriate treatment, as prescribed.
- Institute fall measures because of potential for adverse CNS effects.

## PATIENT TEACHING

- Instruct patient to take tablet whole with liquid beverage. Caution against chewing, crushing, or splitting it because it's designed to release drug at a controlled rate.
- Explain that shell of tablet will be eliminated in stool and that patient need not worry if he sees tablet in stool.
- Urge patient to rise slowly from sitting or lying position to minimize orthostatic hypotension.
- Caution patient to avoid hazardous activities until CNS effects of drug are known. Review fall precautions with patient as well.
- Advise patient to avoid activities that may cause overheating, such as becoming dehydrated, being exposed to extreme heat, or exercising strenuously.
- Advise female patient of childbearing age to notify prescriber if she intends to become or suspects that she is pregnant during therapy because neonates exposed to paliperidone during the third trimester of pregnancy are at risk for extrapyramidal and/or withdrawal symptoms following delivery. If pregnancy occurs, encourage patient to enroll in the pregnancy registry.
- Inform mothers who wish to breastfeed to discuss breastfeeding with prescriber before doing so, because paliperidone is present in breast milk.

and may cause adverse effects in infant. If breastfeeding occurs, instruct mother to monitor her infant for abnormal muscle movements, excess sedation, failure to thrive, jitteriness, or tremors.

- Alert the patient who experiences hyperprolactinemia as a result of paliperidone therapy that reproductive function may become impaired. If this is a concern for the patient, she should consult prescriber.
- Instruct patient to alert prescriber immediately if he experiences any persistent, severe, or unusual signs and symptoms.
- Tell patient to contact prescriber if abnormal movements occur.
- Instruct patient with diabetes to monitor her blood glucose level closely, as drug can affect glycemic control. Also review signs and symptoms of hyperglycemia with all patients and tell them to notify prescriber if present.
- Tell male patients that painful or prolonged penile erections can occur while taking paliperidone. Instruct him to seek immediate emergency medical attention if this occurs.
- Advise patient to notify all prescribers of paliperidone therapy and not to take over-the-counter preparations, including herbal products, without consulting prescriber.

## palonosetron hydrochloride

**Aloxi**

### **Class and Category**

*Pharmacologic class:* Selective serotonin subtype 3 (5-HT<sub>3</sub>) receptor antagonist

*Therapeutic class:* Antiemetic

### **Indications and Dosages**

- *To prevent acute and delayed nausea and vomiting from chemotherapy*

## **I.V. INJECTION**

**Adults.** 0.25 mg over 30 sec about 30 min before start of chemotherapy.

## **I.V. INFUSION**

*Infants 1 month of age and over to less than 17 years.* 20 mcg/kg over 15 min about 30 min before start of chemotherapy. *Maximum: 1.5 mg.*

- *To prevent postoperative nausea and vomiting for up to 24 hr after surgery*

## **I.V. INJECTION**

**Adults.** 0.075 mg over 10 sec immediately before induction of anesthesia.

## **Incompatibilities**

Palonosetron shouldn't be mixed with any other drug.

## **Contraindications**

Hypersensitivity to palonosetron or its components

## **Interactions**

### **DRUGS**

*5-HT<sub>3</sub> receptor antagonists, selective serotonin reuptake inhibitors, serotonin and noradrenaline reuptake inhibitors:*  
Increased risk of serotonin syndrome

# Adverse Reactions

**CNS:** Anxiety, dizziness, drowsiness, dyskinesia, fatigue, headache, insomnia, **serotonin syndrome**, weakness

**CV:** **Bradycardia**, **hypotension**, **prolonged QT interval**, tachycardia

**GI:** Abdominal pain, constipation, diarrhea

**SKIN:** Dermatitis, pruritus, rash

**Other:** **Hyperkalemia**, **hypersensitivity reactions**, injection-site reaction (burning, discomfort, induration, pain)

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use palonosetron cautiously in patients who have or may develop prolonged cardiac conduction intervals—especially QT interval—such as those with congenital QT syndrome, hypokalemia, or hypomagnesemia; those taking an antiarrhythmic, a diuretic known to induce electrolyte abnormalities, or another drug that may prolong QT interval; and those who have received cumulative high-dose anthracycline therapy. With these patients, obtain a baseline ECG before giving palonosetron; repeat the ECG 15 minutes or 24 hours after giving drug, as ordered. Notify prescriber of any delayed conduction.

- Flush I.V. line with normal saline solution before and after giving I.V. palonosetron.
- Use either the single-dose vial or the pre-filled syringe to administer a 0.25-mg dose. Do not use the pre-filled syringe to administer a dose other than 0.25 mg.
- Closely monitor any patient hypersensitive to other selective serotonin receptor antagonists for a similar reaction. If a reaction occurs, notify prescriber immediately.

## Mechanism of Action

Chemotherapy may induce nausea and vomiting by irritating the small intestine's mucosa, causing mucosal enterochromaffin cells to release serotonin (5-HT<sub>3</sub>).

The 5-HT<sub>3</sub> stimulates sympathetic receptors on afferent vagal nerve endings, and the vagus nerve causes the vomiting reflex.

Palonosetron selectively blocks these 5-HT<sub>3</sub> receptors. By keeping the vagus nerve from inducing the vomiting reflex, drug reduces or prevents nausea and vomiting. It also may block 5-HT<sub>3</sub> receptors centrally, in the brain's chemoreceptor trigger zone.

Description

**WARNING** Monitor patient closely for serotonin syndrome, which is characterized by agitation, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening, and provide supportive care.

## PATIENT TEACHING

- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Instruct patient to notify prescriber of any hypersensitivity reaction, such as allergic dermatitis or rash.

## pamidronate disodium

**Aredia**

### Class and Category

*Pharmacologic class:* Bisphosphonate

*Therapeutic class:* Antiosteoporotic

### Indications and Dosages

- *To treat moderate or severe cancer-induced hypercalcemia*

#### I.V. INFUSION

**Adults.** 60 to 90 mg over 2 to 24 hr as a single dose when corrected serum calcium level is 12 to 13.5 mg/dl; 90 mg over 2 to 24 hr when corrected serum calcium level is greater than 13.5 mg/dl. May be repeated as prescribed after 7 days if hypercalcemia recurs.

- *To treat moderate to severe Paget's disease of bone*

#### I.V. INFUSION

**Adults.** 30 mg daily over 4 hr on 3 consecutive days for a total dose of 90 mg. Repeated as needed and tolerated.

- *To treat osteolytic bone metastases of breast cancer*

## **I.V. INFUSION**

**Adults.** 90 mg over 2 hr every 3 to 4 wk.

- *To treat osteolytic bone lesions of multiple myeloma*

## **I.V. INFUSION**

**Adults.** 90 mg over 4 hr every mo.

***DOSAGE ADJUSTMENT*** For patients with renal deterioration (normal baseline creatinine but an increase of 0.5 mg/dl or more or an abnormal baseline creatinine with an increase of 1 mg/dl or more) being treated for osteolytic bone metastases of breast cancer or osteolytic bone lesions of multiple myeloma, retreatment given only after creatinine has returned to within 10% of the baseline value.

## **Mechanism of Action**

Inhibits bone resorption, possibly by impairing attachment of osteoclast precursors to mineralized bone matrix, thus reducing the rate of bone turnover in Paget's disease and osteolytic metastases. Pamidronate also reduces the flow of calcium from resorbing bone into bloodstream.

## **Incompatibilities**

Don't mix pamidronate with calcium-containing infusion solutions, such as Ringer's solution.

## **Contraindications**

Hypersensitivity to pamidronate, other bisphosphonates, or their components

# Interactions

## DRUGS

*nephrotoxic drugs*: Increased risk of nephrotoxicity

*thalidomide*: Increased risk of renal dysfunction in patients with multiple myeloma

## Adverse Reactions

**CNS**: Confusion, fever, psychosis, visual hallucinations

**CV**: **Hypotension**

**EENT**: Conjunctivitis, ocular inflammation

**GI**: Abdominal cramps, anorexia, **GI bleeding**, indigestion, nausea, vomiting

**GU**: **Azotemia**, focal segmental glomerulosclerosis, glomerulonephropathies, hematuria, **nephritis**, **nephrotic syndrome**, **renal toxicity leading to failure**, renal tubular disorders

**HEME**: **Leukopenia**, **lymphopenia**

**MS**: Atypical fractures of femur; muscle spasms or stiffness; osteonecrosis (mainly of jaw); severe bone, joint or muscle pain

**RESP**: **Adult respiratory distress syndrome**, dyspnea, **interstitial lung disease**

**SKIN**: Pruritus, rash

**Other**: **Anaphylaxis**, **angioedema**, flu-like symptoms, **hyperkalemia**, **hyponatremia**, **hypocalcemia**, **hypokalemia**, **hypomagnesemia**, **hypophosphatemia**, injection-site pain and swelling, reactivation of herpes simplex and zoster infections

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as skeletal and other abnormalities. This risk includes posttreatment if a woman becomes pregnant.
- Drug is not recommended for use during pregnancy.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Make sure patient has had a dental checkup before invasive dental procedures during pamidronate therapy, especially if he has cancer; is receiving chemotherapy, a corticosteroid, or head or neck radiation; or has poor oral hygiene. Risk of osteonecrosis is increased in these patients.
- Obtain serum creatinine level before each treatment, as ordered. Notify prescriber of abnormal results because drug may have to be withheld or dosage adjusted until creatinine level returns to normal.

**WARNING** Be aware that no more than 90 mg should be given at any one time because of increased risk of serious adverse effect on kidneys.

- Monitor patient's CBC differential; hematocrit and hemoglobin; and serum electrolytes including calcium, magnesium, and phosphate levels, as ordered throughout therapy because abnormalities may occur.
- Monitor patient for hypocalcemia, especially if patient has had thyroid surgery.
- Stay alert for fever during first 3 days of therapy, especially in patients receiving high doses. If fever develops, obtain patient's CBC with differential, as ordered.
- Assess patient with anemia, leukopenia, or thrombocytopenia for worsening of the condition during first 2 weeks of therapy.

## PATIENT TEACHING

- Emphasize need to comply with prescribed administration schedule for pamidronate.
- Advise patient to avoid calcium and vitamin D supplements during therapy.
- Instruct patient on proper oral hygiene and on need to notify prescriber about upcoming invasive dental procedures.
- Advise women of childbearing age to alert prescriber if she suspects or knows she is pregnant.
- Instruct patient to report to prescriber any new or unusual pain in hip or thigh in the absence of trauma.

## pantoprazole sodium

**Pantoloc (CAN), Protonix, Protonix I.V.**

### Class and Category

*Pharmacologic class:* Proton pump inhibitor

*Therapeutic class:* Antiulcer

### Indications and Dosages

- *To treat erosive esophagitis associated with gastroesophageal reflux disease (GERD) short-term*

#### **DELAYED-RELEASE TABLETS**

**Adults.** 40 mg daily for up to 8 wk. Repeated for another 4 to 8 wk if healing doesn't occur.

**Children age 5 years and older weighing 40 kg (88 lb) or more.** 40 mg once daily for up to 8 wk.

**Children age 5 years and older weighing 15 kg (33 lb) up to 40 kg (88 lb).** 20 mg once daily for up to 8 wks.

## **DELAYED-RELEASE ORAL SUSPENSION**

**Adults.** 40 mg daily given 30 min before a meal for up to 8 wk. Repeated for another 4 to 8 wk if healing doesn't occur.

**Children age 5 years and over weighing 40 kg (88 lb) or more.** 40 mg once daily given 30 min before a meal for up to 8 wks.

**Children age 5 and older weighing 15 kg (33 lb) up to 40 kg (88 lb).** 20 mg once daily given 30 min before a meal for up to 8 wks.

## **I.V. INFUSION**

**Adults.** 40 mg daily infused over 2 or 15 min for 7 to 10 days, followed by oral doses.

- *To maintain healing of erosive esophagitis and reduce relapse of daytime and nighttime symptoms in patients with GERD*

## **DELAYED-RELEASE TABLETS**

**Adults.** 40 mg daily for up to 12 mo.

## **DELAYED-RELEASE ORAL SUSPENSION**

**Adults.** 40 mg daily given 30 min before a meal for up to 12 mo.

- *To treat pathological hypersecretion conditions, including Zollinger-Ellison*

## **DELAYED-RELEASE TABLETS**

**Adults.** 40 mg twice daily. *Maximum:* 240 mg daily.

## DELAYED-RELEASE ORAL SUSPENSION

**Adults.** 40 mg twice daily given 30 minutes before a meal, dosage adjusted as needed. *Maximum:* 240 mg daily.

## I.V. INFUSION

**Adults.** 80 mg every 12 hr infused over 2 or 15 min; adjusted based on patient's acid output measurements up to 80 mg every 8 hr. *Maximum:* 240 mg daily; no more than 6 days of therapy.

Route	Onset	Peak	Duration
P.O.	1 day	1 wk	1 wk
I.V.	1 day	Unknown	1 wk

## Mechanism of Action

Interferes with gastric acid secretion by inhibiting the hydrogen-potassium-adenosine triphosphatase ( $H^+$ - $K^+$ -ATPase) enzyme system, or proton pump, in gastric parietal cells. Normally, the proton pump uses energy from hydrolysis of ATPase to drive  $H^+$  and chloride ( $Cl^-$ ) out of parietal cells and into the stomach lumen in exchange for potassium ( $K^+$ ), which leaves the stomach lumen and enters parietal cells. After this exchange,  $H^+$  and  $Cl^-$  combine in the stomach to form hydrochloric acid (HCl). Pantoprazole irreversibly inhibits the final step in gastric acid production by blocking the exchange of intracellular  $H^+$  and extracellular  $K^+$ , thus preventing  $H^+$  from entering the stomach and additional HCl from forming.

# Incompatibilities

Midazolam and products containing zinc may cause precipitation or discoloration.

# Contraindications

Concurrent therapy with rilpivirine-containing products, hypersensitivity to pantoprazole, substituted benzimidazoles, or their components

# Interactions

## DRUGS

*atazanavir, nelfinavir, rilpivirine*: Significantly decreased plasma levels of these drugs reducing antiviral effect; possible increased risk of drug resistance

*dasatinib, erlotinib, iron salts, itraconazole, ketoconazole, mycophenolate mofetil, nilotinib*: Possible decreased absorption of these drugs and decreased effectiveness

*methotrexate*: Increased risk of methotrexate toxicities

*saquinavir*: Possibly increased risk of antiretroviral toxicity

*warfarin*: Increased INR, PT, and bleeding risk

# Adverse Reactions

**CNS:** Anxiety, asthenia, confusion, depression, dizziness, fatigue, fever, hallucinations, headache, hypertonia, hypokinesia, insomnia, malaise, migraine, somnolence, speech disorder, vertigo

**CV:** Chest pain, elevated triglycerides, hypercholesterolemia, hyperlipidemia

**EENT:** Anterior ischemic optic neuropathy, blurred vision, dry mouth, increased salivation, pharyngitis, rhinitis,

sinusitis, taste disorder, tinnitus

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, atrophic gastritis, *Clostridium difficile-associated diarrhea*, constipation, diarrhea, elevated liver enzymes, flatulence, fundic gland polyps (long-term use), gastroenteritis, *hepatic failure*, *hepatitis*, *hepatotoxicity*, indigestion, jaundice, nausea, *pancreatitis*, vomiting

**GU:** Elevated serum creatinine level, interstitial nephritis

**HEME:** *Agranulocytosis*, *leukopenia*, *pancytopenia*, *thrombocytopenia*

**MS:** Arthralgia, back or neck pain, bone fracture, myalgia, *rhabdomyolysis*

**RESP:** Bronchitis, dyspnea, increased cough, upper respiratory tract infection

**SKIN:** Cutaneous lupus erythematosus, *erythema multiforme*, photosensitivity, pruritus, rash, *Stevens-Johnson syndrome*, *toxic epidermal necrolysis*

**Other:** *Anaphylaxis*, *angioedema*, elevated creatine kinase and phosphokinase levels, flu-like symptoms, generalized pain, hyperuricemia, *hypomagnesemia*, *hyponatremia*, infection, injection-site reaction, systemic lupus erythematosus, vitamin B<sup>12</sup> deficiency weight changes

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Ensure the continuity of gastric acid suppression during transition from oral to I.V. pantoprazole (or vice versa) because even a brief interruption of effective suppression can lead to serious complications.
- Don't give pantoprazole within 4 weeks of testing for *Helicobacter pylori* because antibiotics, bismuth preparations, and proton pump inhibitors suppress *H. pylori* and may lead to false-negative results. Drug also may cause false-positive results in urine screening tests for tetrahydrocannabinol. Consult guidelines for pantoprazole use before testing.
- Administer delayed-release oral suspension 30 minutes before a meal mixed in apple juice or applesauce or, if given through a nasogastric tube, mixed in apple juice only. Do not mix the oral suspension in liquids other than apple juice, or foods other than applesauce because proper pH is necessary for stability. When mixing with applesauce, administer within 10 minutes and encourage patient to take repeated sips of water to make sure granules are washed down into the stomach. When mixing with apple juice, use only 1 teaspoon of apple juice to mix granules in, stir for 5 seconds (granules will not dissolve) and give immediately to patient to drink. After administration, rinse the container once or twice with more apple juice and give to patient to drink to ensure full dose has been given.
- Flush I.V. line with D<sub>5</sub>W, normal saline solution, or lactated Ringer's injection before and after giving drug.
- When giving I.V. over 2 minutes, reconstitute with 10 ml of normal saline injection. Solution may be stored up to 2 hours at room temperature.
- When giving I.V. over 15 minutes, reconstitute with 10 ml normal saline injection. Then, further reconstitute with 100 ml (for GERD) or 80 ml (for pathological hypersecretion in Zollinger-Ellison syndrome) of D<sub>5</sub>W, normal saline injection, or lactated Ringer's injection. Solution may be stored up to 2 hours before further dilution and up to 22 hours before use.
- Expect to monitor PT or INR during therapy if patient takes an oral anticoagulant.
- Be aware that if therapy lasts more than 3 years, patient may not be able to absorb vitamin B<sub>12</sub> because of achlorhydria or hypochlorhydria.

Treatment for cyanocobalamin deficiency may be needed.

- Monitor patient's urine output because pantoprazole may cause acute interstitial nephritis. Notify prescriber if urine output decreases or there is blood in the patient's urine.
- Monitor patient for bone fracture, especially in patients receiving multiple daily doses for more than a year because proton pump inhibitors, such as pantoprazole, increase risk of osteoporosis-related fractures of the hip, spine, or wrist.
- Monitor patient for diarrhea from *C. difficile* which can occur with or without antibiotics in patients taking pantoprazole. If severe diarrhea occurs, notify prescriber and expect to withhold drug and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.
- Be aware that a symptomatic response to the drug does not rule out the presence of a gastric tumor.
- Monitor the patient, especially the patient on long-term therapy for hypomagnesemia. If patient is to remain on pantoprazole long-term, expect to monitor the patient's serum magnesium level, as ordered, and if level becomes low, anticipate magnesium replacement therapy to be given and pantoprazole to be discontinued.
- Know that both cutaneous and systemic lupus erythematosus have occurred within days to years after proton pump therapy such as pantoprazole was initiated. The most common symptoms presented were arthralgia, cytopenia, and rash. Report such findings to prescriber.
- Know that proton pump inhibitors such as pantoprazole should not be given longer than medically necessary.
- Expect drug to be withheld for at least 14 days before assessment of serum chromogranin A levels are performed, because levels increase when gastric acidity is decreased and thus interfere with diagnostic investigations for neuroendocrine tumors.
- Be aware that pantoprazole may result in false positive urine screening tests for tetrahydrocannabinol.

## **PATIENT TEACHING**

- Instruct patient to swallow pantoprazole tablets whole and not to chew or crush them. Warn patient not to exceed dosage or take for longer than prescribed, as long-term use increases risk of serious adverse reactions.
- Tell patient to take delayed-release oral suspension 30 minutes before a meal mixed in apple juice or applesauce; no other liquid or food should be

used. When mixing with applesauce, tell patient to take mixture within 10 minutes and then to take repeated sips of water to make sure granules are washed down into the stomach. When mixing with apple juice, tell patient to use only 1 teaspoon of apple juice to mix granules in, stir for 5 seconds (granules will not dissolve) and drink immediately. After drinking, tell patient to rinse the container once or twice with more apple juice and then drink to ensure full dose has been given.

- Advise patient to expect relief of symptoms within 2 weeks of starting therapy. Tell patient to notify prescriber if he has a suboptimal response to drug or an early symptomatic relapse.
- Advise patient who takes warfarin to follow bleeding precautions and to notify prescriber immediately if bleeding occurs.
- Instruct patient to notify prescriber if diarrhea occurs and becomes prolonged or severe.
- Advise patient to notify prescriber if patient notices he is experiencing a decrease in the amount of urine voided or there is blood in his urine. Also tell him to notify prescriber if he experiences new or worsening joint pain or a rash on his arms or cheeks that gets worse in the sun.
- Remind patient to notify all prescribers of pantoprazole use and not to take any over-the-counter medication, including herbal supplements, without discussing with prescriber.
- Advise patient taking pantoprazole for longer than 3 years to alert prescriber if he experiences signs and symptoms of vitamin B<sub>12</sub> deficiency such as constipation or diarrhea, heart palpitations, mental problems such as depression or memory loss, pale skin, or feeling light-headed, tired, or weak. Also advise him to report any persistent, severe, or unusual signs or symptoms that may be suggestive of other adverse effects such as hypomagnesemia.
- Instruct women of childbearing age to notify prescriber if pregnancy is suspected or occurs, because drug may cause fetal harm.

## paroxetine hydrochloride

**Paxil, Paxil CR**

## paroxetine mesylate

# Brisdelle, Pexeva

## Class and Category

*Pharmacologic class:* Selective serotonin reuptake inhibitor (SSRI)

*Therapeutic class:* Antianxiety, antidepressant, antiobsessional, antipanic, premenstrual analgesic

## Indications and Dosages

➤ *To treat major depression*

### **C.R. TABLETS (PAXIL CR)**

**Adults.** *Initial:* 25 mg daily, increased as prescribed and tolerated by 12.5 mg daily every wk. *Maximum:* 62.5 mg daily.

### **ORAL SUSPENSION (PAXIL), TABLETS (PAXIL, PEXEVA)**

**Adults.** *Initial:* 20 mg daily in the morning, increased as prescribed and tolerated by 10 mg daily every wk.

*Maximum:* 50 mg daily.

➤ *To treat obsessive-compulsive disorder*

### **ORAL SUSPENSION (PAXIL), TABLETS (PAXIL, PEXEVA)**

**Adults.** *Initial:* 20 mg daily in the morning, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 60 mg daily.

*Maximum:* 60 mg daily.

- *To treat panic disorder*

### **C.R. TABLETS (PAXIL CR)**

**Adults.** *Initial:* 12.5 mg daily, increased by 12.5 mg daily every wk as needed.

*Maximum:* 75 mg daily.

### **ORAL SUSPENSION (PAXIL), TABLETS (PAXIL, PEXEVA)**

**Adults.** *Initial:* 10 mg daily in the morning, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 10 to 60 mg daily.

*Maximum:* 60 mg daily.

- *To treat social anxiety disorder*

### **C.R. TABLETS (PAXIL CR)**

**Adults.** *Initial:* 12.5 mg daily in the morning, increased by 12.5 mg daily every wk as needed. *Maximum:* 37.5 mg daily.

### **ORAL SUSPENSION (PAXIL), TABLETS (PAXIL)**

**Adults.** *Initial:* 20 mg daily in the morning, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 60 mg daily.

*Maximum:* 50 mg daily.

- *To treat generalized anxiety disorder*

### **ORAL SUSPENSION (PAXIL), TABLETS (PAXIL, PEXEVA)**

**Adults.** *Initial:* 20 mg daily in the morning, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 50 mg daily.

*Maximum: 50 mg daily.*

➤ *To treat posttraumatic stress disorder*

## **ORAL SUSPENSION, TABLETS (PAXIL)**

**Adults.** *Initial:* 20 mg daily, increased as prescribed and tolerated by 10 mg daily every wk. *Usual:* 20 to 50 mg daily. *Maximum:* 50 mg daily.

➤ *To treat premenstrual dysphoric disorder*

## **C.R. TABLETS (PAXIL CR)**

**Adults.** *Initial:* 12.5 mg daily in the morning, increased as needed after 1 wk to 25 mg daily. Or, 12.5 mg daily in the morning only during luteal phase of menstrual cycle (2-wk period before onset of monthly cycle), increased as needed after 1 wk to 25 mg daily in the morning during luteal phase of menstrual cycle.

***DOSAGE ADJUSTMENT*** For patients who are debilitated, elderly, or have severe hepatic or renal dysfunction, initially 10 mg daily; maximum, 40 mg daily. For these same patients who are taking C.R. tablets, initial dose is 12.5 mg but dosage may need to be reduced and titration intervals increased, if needed. If these patients are being treated for major depressive disorder or panic disorder, dosage should not exceed 50 mg daily and for social anxiety disorder dosage should not exceed 37.5 mg daily.

➤ *To treat moderate to severe vasomotor symptoms associated with menopause*

## **CAPSULES (BRISDELLE)**

**Adults.** 7.5 mg once daily at bedtime.

Route	Onset	Peak	Duration
P.O.	1–4 wk	Unknown	Unknown

## Mechanism of Action

Exerts antianxiety, antidepressant, antiobsessional, and antipanic effects as well as relieving symptoms associated with premenstrual dysphoric disorder and hot flashes associated with menopause by potentiating serotonin activity in CNS and inhibiting serotonin reuptake at presynaptic neuronal membrane. Blocked serotonin reuptake increases levels and prolongs activity of serotonin at synaptic receptor sites.

## Contraindications

Hypersensitivity to paroxetine or its components, pimozide or thioridazine therapy, pregnancy (Brisdelle), use within 14 days of an MAO inhibitor including linezolid or methylene blue I.V.

## Interactions

### DRUGS

*amphetamines, buspirone, cisapride, fentanyl, isoniazid, linezolid, lithium, methylene blue (I.V.), MAO inhibitors, other selective serotonin reuptake inhibitors, other serotonin norephinerine reuptake inhibitors, procarbazine, St. John's wort, tramadol, tricyclic antidepressants, triptans, tryptophan:* Possibly increased risk of serotonin syndrome

*aspirin, NSAIDs, warfarin:* Increased anticoagulant activity and risk of bleeding

*atomoxetine; risperidone; other drugs metabolized by CYP2D6, such as amitriptyline, desipramine, fluoxetine, imipramine, phenothiazines, type IC antiarrhythmics:* Increased plasma levels of these drugs

*cimetidine*: Possibly increased blood paroxetine level  
*digoxin*: Possibly decreased digoxin effects  
*drugs highly protein bound*: Increased adverse reactions of these drugs and paroxetine  
*fosamprenavir/ritonavir*: Significantly decreased plasma levels of paroxetine  
*phenytoin*: Possibly altered levels of both drugs  
*pimozide*: Increased risk of prolonged QT interval  
*procyclidine*: Increased blood procyclidine level and anticholinergic effects  
*tamoxifen*: Decreased tamoxifen effectiveness  
*theophylline*: Possibly increased blood theophylline level and risk of toxicity  
*thioridazine*: Increased thioridazine level, possibly leading to prolonged QT interval and life-threatening ventricular arrhythmias  
*tricyclic antidepressants*: Increased blood antidepressant levels; increased risk of toxicity, including seizures

## ACTIVITIES

*alcohol use*: Possibly altered psychomotor function

## Adverse Reactions

**CNS**: Agitation, akathisia, asthenia, confusion, decreased concentration, dizziness, drowsiness, emotional lability, hallucinations, headache, hypomania, insomnia, mania, **neuroleptic malignant syndrome**, psychomotor agitation, restlessness, **seizures**, **serotonin syndrome**, somnolence, **suicidal ideation**, tremor

**CV**: Palpitations, tachycardia, **torsades de pointes**, **ventricular fibrillation or ventricular tachycardia**

**EENT**: Angle-closure glaucoma, blurred vision, dry mouth, rhinitis, taste perversion

**GI:** Abdominal cramps or pain, anorexia, constipation, diarrhea, flatulence, nausea, vomiting

**GU:** Decreased libido, difficult ejaculation, impotence, sexual dysfunction, urine retention

**HEME:** **Bleeding events**

**MS:** Back pain, bone fracture, myalgia, myasthenia, myopathy

**SKIN:** Diaphoresis, rash, **Stevens-Johnson syndrome**

**Other:** **Hyponatremia**, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug causes fetal harm with congenital malformations, particularly cardiovascular malformations with exposure in first trimester.
- When drug is used late in the third trimester, the neonate may develop complications requiring prolonged hospitalization, respiratory support, and tube feeding.
- Drug is not recommended for use in pregnant women and is contraindicated for treatment of vasomotor symptoms during pregnancy.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Drug may affect sperm quality, which may affect fertility in some men.

## Nursing Considerations

- Be aware that Brisdelle is not used to treat any psychiatric condition because it contains a lower dose of paroxetine.
- Shake oral suspension well. Measure with a calibrated device or an oral syringe.
- Don't give enteric-coated form with antacids.
- Watch for akathisia (inner sense of restlessness) and psychomotor agitation, especially during the first few weeks of therapy.
- Watch patient closely (especially young adults), for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.
- Watch for mania, which may result from any antidepressant in a susceptible patient.
- Monitor patient closely for evidence of GI bleeding, especially if patient also takes a drug known to cause GI bleeding, such as aspirin, an NSAID, or warfarin.

**WARNING** Monitor patient closely for serotonin syndrome exhibited by agitation, hallucinations, coma, diarrhea, hallucinations, hyperreflexia, hyperthermia, incoordination, labile blood pressure, nausea, tachycardia, or vomiting. Notify prescriber immediately because serotonin syndrome may be life-threatening, and provide supportive care.

**WARNING** Be aware that serotonin syndrome in its most severe form may resemble neuroleptic malignant syndrome, which includes autonomic instability with possibly rapid changes in mental status and vital signs, hyperthermia, and muscle rigidity. Stop drug immediately, and provide supportive care.

- To minimize adverse reactions, expect to taper drug rather than stop it abruptly.
- Be aware that pathological fractures have been associated with antidepressant therapy. Monitor patient for unexplained bone pain, bruising, joint tenderness, or swelling.

# PATIENT TEACHING

- Advise patient to take paroxetine in the morning to minimize insomnia and to take it with food if adverse GI reactions develop.
- Instruct patient to avoid taking C.R. paroxetine within 2 hours of an antacid.
- Tell patient to swallow C.R. tablets whole and not to chew, crush, or cut them.
- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have eye exam before starting therapy to see if he is at risk.
- Suggest that patient avoid hazardous activities until drug's CNS effects are known.
- Tell family or caregiver to observe patient closely for suicidal tendencies, especially when therapy starts or dosage changes and especially if patient is a young adult.
- Explain that full effect may take 4 weeks.
- Urge patient to avoid alcohol during therapy; effects with paroxetine are unknown.
- Tell patient not to take aspirin or NSAIDs during therapy because they increase the risk of bleeding. If patient takes warfarin, tell her to use bleeding precautions and to notify prescriber at once if bleeding occurs.
- Inform patient that episodes of acute depression may persist for months or longer and that they require continued follow-up.
- Instruct patient not to stop drug abruptly but to taper dosage as instructed.
- Alert female patients of childbearing age that paroxetine may cause birth defects and persistent pulmonary hypertension in the newborn if taken during the first trimester of pregnancy. Emphasize the need to use effective contraception and to notify prescriber if pregnancy occurs or is suspected.
- Caution patient to alert all prescribers about paroxetine therapy because of potentially serious drug interactions.
- Tell patient to notify prescriber if she develops unexplained bone pain, bruising, joint tenderness, or swelling. Also advise patient to report any persistent, severe, or unusual signs and symptoms to prescriber.

**pegfilgrastim**

**Neulasta**

**pegfilgrastim-bmez**

**Ziextenzo**

**pegfilgrastim-cbqv**

**Udenyca**

**pegfilgrastim-jmdb**

**Fulphila**

## **Class and Category**

*Pharmacologic class:* Colony stimulating factor

*Therapeutic class:* Hematopoietic

## **Indications and Dosages**

- *To increase survival in patients acutely exposed to myelosuppressive doses of radiation.*

### **SUBCUTANEOUS INJECTION (NEULASTA)**

**Adults and children weighing 45 kg (99 lb) or more.** 6 mg as soon as possible after exposure, followed by 6 mg 1 wk later.

**Children weighing between 31 and 44 kg (68.2-96.8 lb):** 4 mg as soon as possible after exposure, followed by 4 mg 1 wk later.

**Children weighing between 21 and 30 kg (46.2-66 lb):** 2.5 mg as soon as possible after exposure, followed by 2.5 mg 1 wk later.

**Children weighing between 10 and 20 kg (22-44 lb):** 1.5 mg as soon as possible after exposure, followed by 2.5 mg 1 wk later.

**Children weighing less than 10 kg (22 lb):** 0.1 mg/kg as soon as possible after exposure, followed by 0.1 mg/kg 1 wk later.

➤ *To reduce the risk of infection, as manifested by febrile neutropenia, in patients with nonmyeloid malignancies receiving myelosuppressive chemotherapy*

## **SUBCUTANEOUS INJECTION (FULPHILA, NEULASTA, UDENYCA, ZIEXTENZO)**

**Adults and children weighing more than 45 kg (99 lb):** 6 mg with each chemotherapy cycle.

**Children weighing between 31 and 44 kg (68.2-96.8 lb):** 4 mg with each chemotherapy cycle.

**Children weighing between 21 and 30 kg (46.2-66 lb):** 2.5 mg with each chemotherapy cycle.

**Children weighing between 10 and 20 kg (22-44 lb):** 1.5 mg with each chemotherapy cycle.

**Children weighing less than 10 kg (22 lb):** 0.1 mg/kg with each chemotherapy cycle.

For both adults and children, dose given no sooner than 24 hr after chemotherapy administration and no later than 14 days before next chemotherapy administration.

# Mechanism of Action

Induces formation of neutrophil progenitor cells by binding to receptors on granulocytes, which then divide.

Pegfilgrastim also potentiates the effects of mature neutrophils, thus reducing fever and the risk of infection from severe neutropenia. It is pharmacologically identical to human granulocyte colony-stimulating factor.

# Contraindications

Hypersensitivity to filgrastim, pegfilgrastim, or their components

# Interactions

## DRUGS

*lithium*: Increased neutrophil production

# Adverse Reactions

**CNS:** Fever

**CV:** **Aortitis**, edema, **hypotension**

**GI:** Elevated liver enzymes, **splenic rupture**, splenomegaly

**GU:** Elevated uric acid level glomerulonephritis

**HEME:** **Capillary leak syndrome**, **hemoconcentration**, leukocytosis, **sickle cell crisis**

**MS:** Bone or extremity pain

**RESP:** **Acute respiratory distress syndrome**, **alveolar hemorrhage**, dyspnea, **hypoxia**, **pulmonary infiltrates**

**SKIN:** Acute febrile neutrophilic dermatosis (Sweet's syndrome), contact dermatitis (on-body injector),

cutaneous vasculitis, erythema, flushing, pruritus, rash, urticaria

**Other:** **Anaphylaxis, angioedema**, antibody formation to pegfilgrastim, application-site reactions with on-body injector (bruising, discomfort, erythema, hemorrhage, pain), hypoalbuminemia, injection-site reactions (erythema, induration, pain)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Avoid giving pegfilgrastim for 14 days before and 24 hours after cytotoxic chemotherapy.
- Check CBC, hematocrit, and platelet count before and periodically during therapy.
- Let drug warm to room temperature for 30 minutes before injection. Administer subcutaneously via a single-dose prefilled syringe for manual use. Be aware, though, now that there is an on-body injector for Neulasta, which is co-packaged with a single-dose prefilled syringe, that the on-body injector form of Neulasta is not recommended for patients with hematopoietic subsyndrome or acute radiation syndrome.
- Don't shake the solution.

- Discard drug that contains particles, is discolored, or was stored more than 48 hours at room temperature. Be aware that the needle cap on the prefilled syringes contains dry natural rubber, which is a derivative of latex and should not be used by persons allergic to latex.

**WARNING** Monitor patient for signs of hypersensitivity. If signs of allergy occur, notify prescriber at once. If anaphylaxis occurs, give antihistamine, bronchodilator, corticosteroid, and epinephrine, as ordered. Be aware that the on-body injector of Neulasta may cause application-site and local skin reactions, including contact dermatitis.

**WARNING** Be aware that patients receiving filgrastim (parent drug) have had splenic rupture and acute respiratory distress syndrome, which may be life-threatening. Assess patient for fever, respiratory distress, and upper abdominal or shoulder tip pain and notify prescriber immediately, if present.

- Monitor patient's renal function, as ordered, because drug may cause glomerulonephritis. If renal dysfunction is suspected, notify prescriber and, if confirmed, expect drug to be withheld or dosage reduced.
- Monitor patient for signs and symptoms of aortitis such as abdominal pain, back pain, fever, increased inflammatory markers (C-reactive protein, white blood cell count), or malaise, as drug will have to be discontinued. Know that aortitis may occur as early as the first week after therapy is begun.
- Be aware that transient positive bone imaging changes may occur because of increased hematopoietic activity of the bone marrow in response to pegfilgrastim therapy.
- Assess patients with sickle cell disease for signs of sickle cell crisis; urge hydration. Know that drug should be discontinued if sickle cell crisis occurs.
- Give nonopioid and opioid analgesics, as ordered, if patient experiences bone pain.

**WARNING** Monitor patient for edema and hypotension that may indicate development of capillary leak syndrome. If

present, notify prescriber and be prepared to provide supportive care, as ordered. Be aware that the on-body injector of Neulasta may cause application-site and local skin reactions, including contact dermatitis.

- Store drug at 2° to 8°C (36° to 46°F), and protect from freezing and light.
- Be aware that needle cover contains dry natural rubber and should not be handled by persons with a latex allergy.

## **PATIENT TEACHING**

- Urge patient to report promptly any potentially serious reactions (breathing difficulty, chest tightness, left upper abdominal pain, rash, shoulder tip pain) and evidence of infection (chills, fever).
- Teach patient who will self-administer drug, how to prepare, give, and store drug. However, alert patient that the On-body Injector for drug uses acrylic adhesive, which can cause a significant reaction to those allergic to acrylic adhesive.
- Alert her that needle cover contains dry natural rubber and should not be handled if she has a latex allergy.
- Tell patient to rotate injection sites among abdomen (except for 2 inches around navel), buttocks, outer, upper arms and thighs. Caution her to avoid bruised, hard, red, or tender areas.
- Urge patient to discard used needles and syringes in a puncture-resistant container and not to reuse them.
- Alert patient that missed or partial doses have been reported with the on-body injector Neulasta due to potential device failure. Also tell patient not to reapply the on-body injector Neulasta if it comes off before the full dose is delivered. Instruct patient to notify prescriber immediately if the on-body injector Neulasta has come off or she suspects that the device may not have performed as intended, to get instructions on a possible replacement dose. Warn patient to avoid bumping the on-body injector Neulasta or knocking it off her body. Tell her she should not use additional materials to hold the on-body injector Neulasta in place, as this could dislodge the cannula and lead to a missed or incomplete dose.
- Tell patient to call prescriber immediately if the status light on the on-body injector Neulasta is flashing red. Also tell her not to remove the on-body injector Neulasta until the green light shines continuously. Tell patient to inform all healthcare workers of the presence of the on-body

injector Neulasta, as it should not be exposed to medical imaging studies (CT scan, MRI, ultrasound, or X-ray), oxygen-rich environments, or radiation treatment.

- Remind patient not to use on-body injector Neulasta in the bathtub, hot tubs, saunas, or whirlpools and not to expose it to direct sunlight, as these may affect drug. Tell patient to avoid sleeping on the on-body injector Neulasta or getting cleaning agents, creams, lotions, or oils near the injector, as these products may loosen the adhesive.
- Advise patient to have a caregiver nearby when he administers the first dose and to avoid driving or operating heavy machinery during hours 26 to 29 following application of the on-body injector Neulasta.
- Warn patient to keep the on-body injector Neulasta at least 4 inches away from electrical equipment such as cell phones, cordless telephones, microwaves, and other common appliances, because of possible interference with its function.
- Emphasize the importance of follow-up tests.
- Advise patient to store pegfilgrastim in refrigerator and not to freeze it. Tell her to discard drug if left unrefrigerated for more than 48 hours.

## penicillin G benzathine

**Bicillin L-A, Permapen**

## penicillin G potassium

**Pfizerpen**

## penicillin G procaine

## penicillin G sodium

## penicillin V potassium

# Penicillin-VK

## Class and Category

*Pharmacologic class:* Penicillin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat systemic infections caused by gram-positive organisms (including Bacillus anthracis, Corynebacterium diphtheriae, enterococci, Listeria monocytogenes, Staphylococcus aureus, and S. epidermidis), gram-negative organisms (including Neisseria gonorrhoeae, N. meningitidis, Pasteurella multocida, and Streptobacillus moniliformis [rat-bite fever]), and gram-positive anaerobes (including Actinomyces israelii [actinomycosis], Clostridium perfringens, C. tetani, Peptococcus species, Peptostreptococcus species, and spirochetes, especially Treponema carateum [pinta], T. pallidum, and T. pertenue [yaws])*

## I.V. INFUSION, I.M. INJECTION (PENICILLIN G POTASSIUM, PENICILLIN G SODIUM)

**Adults and children.** Highly individualized based on type and severity of infection. Dosage ranges from 1 to 24 million units daily in divided doses usually every 4 to 6 hr, although some infections may require divided dosing every 2 hr. I.V. infusion given over 1 to 2 hr in adults and over 15 to 30 min in children or as a continuous infusion if using Pfizerpen.

## **I.M. INJECTION (PENICILLIN G PROCAINE)**

**Adults and adolescents.** Highly individualized based on severity and type of infection. Dosages range from 300,000 to 1,200,000 units daily and maybe given in divided doses every 12 hr in some infections.

- *To treat Group A streptococcal respiratory infections*

## **I.M. INJECTION (PENICILLIN G BENZATHINE)**

**Adults and children weighing more than 45 kg (100 lb).** 1.2 million units as a single injection.

**Children weighing 27 to 45 kg (59 to 100 lb).** 900,000 units as a single injection.

**Infants and children weighing less than 27 kg (59 lb).** 300,000 to 600,000 units as single injection.

- *To treat congenital syphilis*

## **I.M. INJECTION (PENICILLIN G BENZATHINE)**

**Children ages 2 to 12.** Dosage adjusted based on adult dosing schedule.

**Children under age 2.** 50,000 units/kg as a single injection. *Maximum:* 2.4 million units/dose.

- *To treat primary, secondary, or latent syphilis*

## **I.M. INJECTION (PENICILLIN G BENZATHINE)**

**Adults.** 2.4 million units as a single injection.

- *To treat late (neurosyphilis or tertiary) syphilis*

## **I.M. INJECTION (PENICILLIN G BENZATHINE)**

**Adults.** 2.4 million units every wk for 3 wk.

- *To provide prophylaxis for glomerulonephritis and rheumatic fever*

## **I.M. INJECTION (PENICILLIN G BENZATHINE)**

**Adults.** 1.2 million units once a month or 600,000 units every 2 wks following an acute attack.

- *To treat bejel, pinta, and yaws caused by susceptible organisms*

## **I.M. INJECTION (PENICILLIN G BENZATHINE)**

**Adults.** 1.2 million units as a single injection.

- *To treat mild to moderate severe upper respiratory tract streptococcal infections, including erysipelas and scarlet fever*

## **ORAL SOLUTION, TABLETS (PENICILLIN V POTASSIUM)**

*Adults and adolescents.* 125 to 250 mg (200,000 to 400,000 units) every 6 to 8 hr for 10 days.

- *To treat mild to moderate pneumococcal infections, mild skin and soft tissue staphylococcal infections, mild to moderate staphylococcal (Vincent's) infection of the oropharynx*

## **ORAL SOLUTION, TABLETS (PENICILLIN V POTASSIUM)**

*Adults and adolescents.* 250 to 500 mg (400,000 to 800,000 units) every 6 to 8 hr.

- *To prevent recurrence following chorea and/or rheumatic fever*

## **ORAL SOLUTION, TABLETS (PENICILLIN V POTASSIUM)**

**Adults.** 125 mg to 250 mg (200,000 to 400,000 units) twice daily on a continuing basis.

- *To provide prophylaxis against bacterial endocarditis in patients with congenital heart disease or rheumatic or other acquired valvular heart disease when undergoing dental procedures or surgical procedures of the upper respiratory tract.*

## **ORAL SOLUTION, TABLETS (PENICILLIN V POTASSIUM)**

**Adults and children over 27 kg (59 lbs).** 2 grams 1 hr before the procedure, and then 1 g 6 hours later.

**Children under 27 kg (59 lbs).** 1 g 1 hr before the procedure, and then 500 mg 6 hr later.

***DOSAGE ADJUSTMENT*** For uremic patient receiving penicillin G potassium or penicillin G sodium with creatinine clearance greater than 10 ml/min, full loading dose given followed by one-half of the loading dose every 4 to 5 hr. For patient receiving penicillin G potassium or penicillin G sodium with creatinine clearance of less than 10 ml/min, full loading dose given followed by one half of the loading dose every 8 to 10 hr.

## **Mechanism of Action**

Inhibits final stage of bacterial cell wall synthesis by competitively binding to penicillin-binding proteins inside the cell wall. Penicillin-binding proteins are responsible for various steps in bacterial cell wall synthesis. By binding to these proteins, penicillin leads to cell wall lysis.

## **Incompatibilities**

Don't mix any penicillin in the same syringe or container with aminoglycosides because aminoglycosides will be inactivated. Don't mix penicillin G with drugs that may result in a pH < 5.5 or pH > 8.

## Contraindications

Hypersensitivity to penicillin or its components

## Interactions

### DRUGS

*aspirin, ethacrynic acid, furosemide, indomethacin, phenylbutazone, probenecid, sulfonamides, thiazide diuretics:* Possibly prolonged blood penicillin level  
*chloramphenicol, erythromycin, sulfonamides, tetracycline:* Possibly interference with penicillin's bactericidal effect

## Adverse Reactions

**CNS:** Confusion, dizziness, dysphasia, hallucinations, headache, lethargy, sciatic nerve irritation, **seizures**

**CV:** Labile blood pressure, palpitations

**EENT:** Black "hairy" tongue, oral candidiasis, stomatitis, taste perversion

**GI:** Abdominal pain, diarrhea, elevated liver enzymes (transient), indigestion, nausea, **pseudomembranous colitis**

**GU:** **Acute interstitial nephritis**, vaginal candidiasis

**MS:** Muscle twitching

**SKIN:** Rash

**Other:** **Electrolyte imbalances**; injection-site necrosis, pain, or redness

# Childbearing Considerations

## PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Obtain body tissue and fluid samples for culture and sensitivity tests as ordered before giving first dose. Expect to begin drug therapy before test results are known.
- Reconstitute vials of penicillin for injection with D<sub>5</sub>W, or sodium chloride for injection, or sterile water for injection.
- Administer penicillin at least 1 hour before other antibiotics.
- Inject I.M. form deep into large muscle mass. Apply ice to relieve pain.

**WARNING** Give penicillin G benzathine and penicillin G procaine only by deep I.M. injection; I.V. injection may be fatal, and intra-arterial injection may cause extensive organ and tissue necrosis.

- Be aware that I.M. drug is absorbed slowly, which may make allergic reactions difficult to treat.
- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to

withhold penicillin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.

- Monitor serum sodium level and assess for early signs of heart failure in patients receiving high doses of penicillin G sodium.
- When giving penicillin G potassium to patient at risk for fluid overload or hypertension, be aware that each gram of penicillin G potassium also contains 1.02 mEq of sodium.

## PATIENT TEACHING

- Instruct patient to report previous allergies to penicillins and to notify prescriber immediately about adverse reactions, including fever.
- Urge patient to tell prescriber if diarrhea develops, even 2 months or more after penicillin therapy ends.
- Inform patient taking penicillin V potassium oral solution that it contains phenylalanine.

## phenazopyridine hydrochloride

**Azo-Standard, Baridium, Nefrecil,  
Phenazo (CAN), Pyridiate, Pyridium,  
Urogesic**

## Class and Category

*Pharmacologic class:* Alpha<sub>1</sub> agonist

*Therapeutic class:* Urinary analgesic

## Indications and Dosages

- *To relieve burning and pain on urination, and urinary frequency and urgency*

## **TABLETS**

**Adults.** 200 mg three times daily with or without food for no longer than 2 days.

## **Mechanism of Action**

Exerts a local anesthetic effect on urinary tract mucosa as drug is excreted in urine. Phenazopyridine's exact mechanism is unknown.

## **Contraindications**

Hypersensitivity to phenazopyridine or its components, renal insufficiency

## **Interactions**

### **DRUGS**

None reported

## **Adverse Reactions**

**CNS:** Headache

**GI:** Indigestion, nausea, vomiting

**GU:** Reddish orange urine

**SKIN:** Pruritus, rash

**Other:** Discoloration of body fluids

## **Childbearing Considerations**

## **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Notify prescriber if yellowish skin or sclerae develop in patient taking phenazopyridine because this may indicate drug accumulation from impaired renal excretion. Expect prescriber to discontinue drug.
- Be aware that phenazopyridine treatment should be limited to 2 days.

## **PATIENT TEACHING**

- Instruct patient not to take drug for longer than 2 days and to notify prescriber if symptoms persist beyond that time.
- Advise patient to take drug with meals if GI distress develops.
- Inform patient that drug turns urine orange to red and may discolor other body fluids, such as tears.
- Advise patient not to wear contact lenses during therapy because they may become stained.

**phenobarbital sodium**

# Class, Category, and Schedule

*Pharmacologic class:* Barbiturate

*Therapeutic class:* Anticonvulsant, sedative-hypnotic

*Controlled substance schedule:* IV

## Indications and Dosages

- *To treat seizures*

### ELIXIR, TABLETS

**Adults.** *Initial:* 50 to 100 mg two or three times daily.

**Children.** 15 to 50 mg two or three times daily.

### I.M. OR I.V. INJECTION

**Adults.** Highly individualized. *Recommendation as a guide:* 20 to 320 mg, repeated in 6 hr, if needed. I.V. injection given slowly not to exceed 60 mg/min.

**Children.** *Highly individualized. Recommendation as a guide:* 4 to 6 mg/kg/day for 7 to 10 days to blood level of 10 to 15 mcg/ml. Alternatively, 10 to 15 mg/kg/day. I.V. injection given slowly over 10 to 15 min.

- *To treat status epilepticus*

### I.V. INJECTION

**Children.** Highly individualized. *Recommendation as a guide:* 15 to 20 mg/kg given slowly over 10 to 15 min.

- *To provide short-term treatment of insomnia*

### ELIXIR, TABLETS

**Adults.** 100 to 320 mg at bedtime.

- *To provide daytime sedation*

## ELIXIR, TABLETS

**Adults.** 30 to 120 mg daily in divided doses twice daily or three times a day.

**Children.** 2 mg/kg three times a day.

## I.M. OR I.V. INJECTION

**Adults.** Highly individualized. *Recommendation as a guide:* 30 to 120 mg daily in divided doses twice daily or three times a day. I.V. injection given slowly not to exceed 60 mg/min.

➤ *To provide preoperative sedation*

## I.M. INJECTION

**Adults.** Highly individualized. *Recommendation as a guide:* 100 to 200 mg 60 to 90 min before surgery.

## I.V. OR I.M. INJECTION

**Children.** Highly individualized. *Recommendation as a guide:* 1 to 3 mg/kg 60 to 90 min before surgery. I.V. injection given slowly over 10 to 15 min.

**DOSAGE ADJUSTMENT** Dosage possibly reduced for debilitated or elderly patients to minimize confusion, depression, and excitement.

Route	Onset	Peak	Duration
P.O.	20-60 min	Unknown	Unknown
I.V.	5 min	30 min	4-6 hr
I.M.	5-20 min	Unknown	4-6 hr

## Mechanism of Action

Inhibits ascending conduction of impulses in the reticular formation, which controls CNS arousal to produce drowsiness, hypnosis, and sedation. Phenobarbital also decreases the spread of seizure activity in cortex, limbic system, and thalamus. It promotes an increased threshold for electrical stimulation in the motor cortex, which may contribute to its anticonvulsant properties.

## Contraindications

Family or personal history of acute intermittent porphyria; history of addiction to hypnotics or sedatives; hypersensitivity to phenobarbital, other barbiturates, or their components; marked liver impairment; severe respiratory disease with airway obstruction or dyspnea

## Interactions

### DRUGS

*anticoagulants*: Decreased anticoagulant activity

*CNS depressants*: Additive depressant effects

*corticosteroids*: Enhanced metabolism of corticosteroids possibly requiring dosage adjustment

*doxycycline*: Shorten half-life of doxycycline for as long as 2 weeks after phenobarbital has been discontinued

*griseofulvin*: Interference with absorption of oral griseofulvin

*MAO inhibitors*: Prolonged phenobarbital effects

*oral contraceptives*: Possibly decreased effectiveness of the contraceptive

*phenytoin*: Metabolism of phenytoin becomes unpredictable

*sodium valproate, valproic acid*: Decreased phenobarbital metabolism

## ACTIVITIES

*alcohol use:* Additive CNS depression

## Adverse Reactions

**CNS:** Anxiety, depression, dizziness, drowsiness, headache, irritability, lethargy, mood changes, paradoxical stimulation, sedation, vertigo

**CV:** **Bradycardia, hypotension**

**EENT:** Miosis, ptosis

**GI:** Constipation, diarrhea, nausea, vomiting

**GU:** Decreased libido, impotence, sexual dysfunction

**MS:** Arthralgia, bone tenderness

**RESP:** **Bronchospasm, respiratory depression**

**SKIN:** Dermatitis, photosensitivity, rash, urticaria

**Other:** Injection-site phlebitis (I.V.), physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- Drug causes fetal harm having been linked to a higher than normal risk for fetal abnormalities.
- Be aware that long-term exposure to drug in utero may cause the neonate to experience acute withdrawal syndrome causing seizures and hyperirritability from birth to a delayed onset of up to 14 days.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- When drug is administered to mother during labor, the neonate, especially if premature, needs to be monitored for respiratory depression.

- Resuscitative equipment needs to be present during labor and delivery.

## **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Be aware that phenobarbital shouldn't be given during third trimester of pregnancy because repeated use can cause dependence in neonate. It also shouldn't be given to breastfeeding women because it may cause CNS depression in infants.
- Use I.V. route cautiously in patients with CV disease, hypotension, pulmonary disease, or shock because drug may cause adverse hemodynamic or respiratory effects.
- Know that because drug can cause respiratory depression, respiratory rate and depth should be assessed before use, especially in patient with bronchopneumonia, pulmonary disease, respiratory tract infection, or status asthmaticus.
- Give elixir undiluted or mix with fruit juice, milk, or water. Use a calibrated device to measure doses.
- If necessary, crush tablets and mix with fluids or food.
- Reconstitute sterile powder with at least 10 ml sterile water for injection. Don't use reconstituted solution if it fails to clear within 5 minutes. Further dilute prescribed dose with normal saline solution or D<sub>5</sub>W and infuse over 30 to 60 minutes.
- Don't give more rapidly than 60 mg/min by I.V. injection.
- For I.V. use, monitor blood pressure, heart rate and rhythm. Anticipate increased risk of hypotension, even at recommended rate. Keep resuscitation equipment readily available.
- For I.M. use, don't inject more than 5 ml into any one I.M. site to prevent sterile abscess formation.
- Be aware that drug may cause physical and psychological dependence.

- Expect that phenobarbital's CNS effects may exacerbate major depression, suicidal tendencies, or other mental disorders.
- Take safety precautions for elderly patients, as appropriate, because they're more likely to experience confusion, depression, and excitement as adverse CNS reactions.
- Anticipate that phenobarbital may cause paradoxical stimulation in children.
- Be aware that drug may trigger signs and symptoms in patients with acute intermittent porphyria.

## PATIENT TEACHING

- Instruct patient to take phenobarbital elixir undiluted or to mix it with fruit juice, milk, or water. Advise her to use a calibrated device to measure doses.
- If patient has trouble swallowing tablets, suggest crushing and adding to fluid or food.
- Caution patient about possible drowsiness and reduced alertness. Advise her to avoid potentially hazardous activities until drug's CNS effects are known.
- Urge patient to avoid alcohol during therapy.
- Inform parents that a child may react with paradoxical excitement. Tell them to notify prescriber if this occurs.
- Instruct woman to report suspected, known, or intended pregnancy.

**phentermine hydrochloride**

**Adipex-P, Lomaira**

## Class, Category, and Schedule

*Chemical class:* Sympathomimetic amine

*Therapeutic class: Anorectic*  
*Controlled substance schedule: IV*

## Indications and Dosages

- *Adjunct for short-term weight reduction in conjunction with behavioral modification, caloric restriction, and exercise in management of exogenous obesity in patients with an initial body mass index greater than or equal to 30 kg/m<sup>2</sup>, or greater than or equal to 27 kg/m<sup>2</sup> in the presence of other risk factors such as controlled hypertension, diabetes, or hyperlipidemia*

### **CAPSULES, TABLETS**

*Adults. Individualized. Initial: 37.5 mg daily half-hour before breakfast or 1 to 2 hr after breakfast, and then dosage adjusted to patient's need.*

***DOSAGE ADJUSTMENT*** For patient with severe renal impairment (creatinine clearance between 15 to 29 ml/min) taking Adipex-P, dosage reduced to 15 mg daily.

## Mechanism of Action

Unknown, although thought to be related to its ability to suppress appetite.

## Contraindications

Agitated states; breastfeeding; during or 14 days after MAO inhibitor therapy; glaucoma; history of cardiovascular disease such as arrhythmias, congestive heart failure, coronary artery disease, stroke, or uncontrolled hypertension; history of drug abuse; hypersensitivity to

phentermine, other sympathomimetic amines, or their components; hyperthyroidism; pregnancy

## Interactions

### DRUGS

*adrenergic neuron blocking drugs:* Possibly decreased hypotensive effect of these drugs

*insulin, oral hypoglycemic drugs:* Possibly increased risk of hypoglycemia

*MAO inhibitors:* Increased risk of hypertensive crisis

### ACTIVITIES

*alcohol use:* Possibly increased incidence of serious adverse reactions

## Adverse Reactions

**CNS:** Dizziness, dysphoria, euphoria, headache, insomnia, overstimulation, psychosis, restlessness, tremor

**CV:** Hypertension, ischemic events, palpitations, **regurgitant cardiac valvular disease**, tachycardia

**EENT:** Dry mouth, unpleasant taste

**GI:** Constipation, diarrhea, other gastrointestinal disturbances

**GU:** Changes in libido, impotence

**RESP:** **Primary pulmonary hypertension**

**SKIN:** Urticaria

**Other:** Physical and psychological dependence

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in pregnancy.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated during breastfeeding.

## Nursing Considerations

- Know that phentermine should not be given to women who are breastfeeding or pregnant because of serious adverse effects to fetus or baby.
- Use cautiously in patients with even mild hypertension, because drug can raise blood pressure; and in patients with diabetes who are taking insulin or oral hypoglycemic agents, as drug may enhance hypoglycemic effects.
- Use cautiously in patients with impaired renal function, especially the elderly, as phentermine is substantially excreted by the kidneys and can cause toxic effects in the presence of renal impairment.

**WARNING** Monitor patient for anginal pain, dyspnea (most common), lower extremity edema, or syncope because a life-threatening disorder, primary pulmonary hypertension, has occurred in patients taking phentermine alone or concomitantly with dexfenfluramine or fenfluramine. If signs or symptoms develop, notify prescriber, expect drug to be discontinued, and assist with diagnostic testing to confirm presence of disorder.

- Know that serious regurgitant cardiac valvular disease has occurred in otherwise healthy patients taking phentermine alone or in combination with dexfenfluramine or fenfluramine. Regularly evaluate patient's heart sounds for presence of murmurs, especially those associated with aortic, mitral, or tricuspid valvular disease.

- Monitor patient's blood pressure regularly, as phentermine therapy may cause hypertension.
- Assess patients with diabetes who are taking insulin or oral hypoglycemic agents for signs and symptoms of hypoglycemia. If persistent or serious hypoglycemia occurs, notify prescriber and expect to adjust the antidiabetic medication dosage, as ordered.

## **PATIENT TEACHING**

- Caution patient to take phentermine exactly as prescribed and not to increase dosage or dosage interval if tolerance to drug develops. Instead, instruct patient to notify prescriber, as drug will have to be discontinued.
- Warn patient that drug is for short-term use only, as the drug may cause physical and/or psychological dependence and can be abused for these effects.
- Inform patient that phentermine therapy is not a substitute for behavioral changes, caloric restriction, and exercise.
- Warn patient not to combine phentermine therapy with other drug products for weight loss, including herbal products, over-the-counter drugs, and prescription drugs. Tell patient to inform all prescribers of phentermine use.
- Caution patient to avoid hazardous activities such as driving or operating machinery until the nervous system effects of the drug are known.
- Tell patient to keep drug out of reach of children and anyone who has a drug addiction and to take measures to prevent drug theft.
- Instruct patient to avoid drinking alcoholic beverages while taking phentermine, as serious adverse reactions may occur.
- Advise patients with diabetes who are taking medication to control their blood glucose levels to watch for low blood glucose reactions. If persistent or severe hypoglycemia occurs, instruct patient to notify prescriber, as dosage of the diabetic medication may have to be reduced. Also advise patient with high blood pressure to monitor blood pressure regularly.

**WARNING** Instruct patient to discontinue phentermine therapy and notify prescriber if chest pain, decrease in exercise tolerance, difficulty breathing, lower extremity swelling, or shortness of breath develop during phentermine therapy.

- Warn women of childbearing age to notify prescriber immediately if pregnancy occurs or is suspected, as drug will have to be discontinued immediately. Also inform women who are breastfeeding that breastfeeding must be avoided during phentermine therapy.

## phenytoin

**Dilantin-125, Dilantin Infatabs**

## phenytoin sodium

**Dilantin, Phenytek**

### Class and Category

*Pharmacologic class:* Hydantoin derivative

*Therapeutic class:* Anticonvulsant

### Indications and Dosages

- *To treat tonic-clonic or psychomotor (temporal) seizures*

### CHEWABLE TABLETS, ORAL SUSPENSION (PHENYTOIN)

**Adults who have received no previous treatment.**

*Initial:* 125 mg suspension or 100 to 125 mg tablet three times a day, adjusted every 7 to 10 days as needed and tolerated.

**Children.** *Initial:* 5 mg/kg daily in divided doses twice daily or three times a day, adjusted as needed and tolerated. *Maintenance:* 4 to 8 mg/kg daily in divided doses twice daily or three times daily. *Maximum for children over the age of 6:* 300 mg daily.

- *To treat tonic-clonic or psychomotor (temporal) seizures; to prevent and treat seizures occurring during or following neurosurgery*

## **EXTENDED RELEASE CAPSULES (PHENYTOIN SODIUM)**

**Adults who have received no previous treatment.**

*Initial:* 100 mg three times daily, adjusted every 7 to 10 days as needed and tolerated to a maximum of 200 mg three times daily. *Maintenance:* 100 mg three or four times daily; 200 mg three times daily, or 300 mg once daily.

***DOSAGE ADJUSTMENT*** For hospitalized patients without hepatic or renal disease, oral loading dose of 400 mg followed in 2 hr by 300 mg, and then followed in 2 more hr by another 300 mg, for a total of 1 g.

**Children.** *Initial:* 5 mg/kg daily in divided doses twice daily or three times a day, adjusted as needed and tolerated. *Maintenance:* 4 to 8 mg/kg daily in divided doses twice daily or three times a day. *Maximum for children over the age of 6:* 300 mg daily.

- *To treat status epilepticus; to prevent or treat seizures during neurosurgery*

## **I.V. INFUSION (PHENYTOIN SODIUM)**

**Adults and adolescents.** *Loading dose:* 10 to 15 mg/kg in 50 ml sodium chloride injection at no more than 50 mg/min. *Maintenance:* 100 mg I.V. or P.O. every 6 to 8 hr.

**Children.** *Loading dose:* 15 to 20 mg/kg at no more than 1 to 3 mg/kg/min or 50 mg/min, whichever is slower.

*Maintenance:* Highly individualized.

**DOSAGE ADJUSTMENT** For elderly patients dosage reduced.

## Mechanism of Action

Limits the spread of seizure activity and the start of new seizures by regulating voltage-dependent calcium and sodium channels in neurons, inhibiting calcium movement across neuronal membranes, and enhancing sodium-potassium ATP activity in neurons and glial cells. These actions all help stabilize the neurons.

## Incompatibilities

Don't mix phenytoin in same syringe with any other drugs or with any I.V. solutions other than sodium chloride for injection because precipitate will form.

## Contraindications

*For all forms:* Concurrent use with delavirdine or nonnucleoside reverse transcriptase inhibitors; history of prior acute hepatotoxicity attributed to phenytoin; hypersensitivity to phenytoin, other hydantoins, or their components; *For I.V. form:* Adams-Stokes syndrome, second and third degree A-V block, sino-atrial block, sinus bradycardia

## Interactions

### DRUGS

*albensazole, antiepileptics (carbamazepine, felbamate, lamotrigine, topiramate, oxcarbazepine), antilipidemic agents (atorvastatin, fluvastatin, simvastatin), antiviral agents (efavirenz, fosamprenavir when given alone, indinavir, lopinavir/ritonavir, nelfinavir, ritonavir, saquinavir), calcium channel blockers (nifedipine, nimodipine, verapamil), chlorpropamide, clozapine, cyclosporine, digoxin, disopyramide, folic acid, methadone, mexiletine, praziquantel, quetiapine: Decreased blood levels of these drugs by phenytoin*

*amiodarone, antidepressants (fluoxetine, fluvoxamine, sertraline), antineoplastic agents (capecitabine, fluorouracil), antiepileptic drugs (ethosuximide, felbamate, oxcarbazepine, topiramate), azoles (fluconazole, ketoconazole, itraconazole, miconazole, voriconazole), chloramphenicol, chlordiazepoxide, disulfiram, estrogen, fluvastatin, gastric acid reducing agents (H<sub>2</sub> antagonist such as cimetidine, omeprazole), isoniazide, methylphenidate, phenothiazines, salicylates, sulfonamides (sulfadiazine, sulfamethizole, sulfamethoxazole-trimethoprim, sulfaphenazole), ticlopidine, tolbutamide, trazodone, warfarin: Possibly increased phenytoin serum levels*

*antiepileptics (carbamazepine, vigabatrin), antineoplastic agents usually in combination (bleomycin, carboplatin, cisplatin, doxorubicin, methotrexate), antiviral agents (fosamprenavir, nelfinavir, ritonavir), diazepam, diazoxide, folic acid, reserpine, rifampin, St. John's wort, theophylline: Possibly decreased phenytoin serum levels*

*antiepileptics (phenobarbital, valproate sodium, valproic acid): Possibly decreased or increased phenytoin serum levels*

*azoles (fluconazole, ketoconazole, itraconazole, posaconazole, voriconazole), antineoplastic agents*

*(irinotecan, paclitaxel, teniposide), corticosteroids, delavirdine, doxycycline, estrogens, furosemide, neuromuscular blocking agents (cisatracurium, pancuronium, rocuronium, vecuronium), oral contraceptives, paroxetine, quinidine, rifampin, sertraline, theophylline, vitamin D, warfarin: Decreased effectiveness of these drugs by phenytoin*

## **ACTIVITIES**

*alcohol use: Additive CNS depression, increased blood phenytoin levels with acute alcohol use; decreased blood phenytoin levels with chronic alcohol use*

## **Adverse Reactions**

**CNS:** Ataxia, cerebellar atrophy, confusion, depression, dizziness, drowsiness, excitement, fever, headache, involuntary motor activity, lethargy, nervousness, peripheral neuropathy, phenytoin-induced dyskinesias, restlessness, slurred speech, **suicidal ideation**, tremor, vertigo, weakness

**CV:** **Bradycardia**, **cardiac arrest**, **hypotension**, periarteritis nodosa, polyarteritis, vasculitis

**EENT:** Amblyopia, conjunctivitis, diplopia, earache, epistaxis, eye pain, gingival hyperplasia, hearing loss, loss of taste, nystagmus, pharyngitis, photophobia, rhinitis, sinusitis, taste perversion, tinnitus

**ENDO:** Gynecomastia, hyperglycemia

**GI:** Abdominal pain, **acute hepatic failure**, anorexia, constipation, diarrhea, epigastric pain, jaundice, hepatic dysfunction, **hepatic necrosis**, **hepatitis**, nausea, vomiting

**GU:** Glycosuria, Peyronie's disease, priapism, **renal failure**

**HEME:** Acute intermittent porphyria (exacerbation), **agranulocytosis**, anemia, eosinophilia, **granulocytopenia**, **leukopenia**, **pancytopenia**, **thrombocytopenia**

**MS:** Arthralgia, arthropathy, bone fractures, decreased bone mineral density, muscle twitching, osteomalacia, polymyositis

**RESP:** **Apnea**, **asthma**, bronchitis, cough, dyspnea, **hypoxia**, increased sputum production, pneumonia, **pneumothorax**, **pulmonary fibrosis**

**SKIN:** **Acute generalized exanthematous pustulosis**, bullous dermatitis, **exfoliative dermatitis**, maculopapular or morbilliform rash, purpuric dermatitis, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, unusual hair growth, urticaria

**Other:** **Angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, facial feature coarsening or enlargement, immunoglobulin abnormalities, injection-site pain, lupus-like symptoms, lymphadenopathy, porphyria, weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- Drug may cause fetal harm such as congenital malformations and adverse developmental outcomes.
- Be aware that a potentially life-threatening bleeding disorder may occur in newborns exposed to drug in utero but can be prevented with vitamin K administration to the mother before delivery and to the neonate after birth.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

- Be aware that decreased serum concentrations of drug may occur during pregnancy requiring frequent monitoring of drug levels in mother throughout the pregnancy.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Know that patients of Asian ancestry who have the genetic allelic variant HLA-B 1502 develop serious and sometimes fatal dermatologic reactions 10 times more often than people without this variant when given carbamazepine, another antiepileptic drug. Because early data suggest a similar effect with phenytoin, this drug shouldn't be used as a substitute for carbamazepine in these patients.

- Be aware that preferred administration routes for phenytoin are oral and I.V. injection. With I.M. administration, phenytoin has a variable absorption rate.
- Know that if patient has difficulty swallowing, prompt (rapid-release) capsules may be opened and contents mixed with food or fluid.
- Shake oral suspension before measuring dose, and use a calibrated measuring device.
- Give phenytoin with or just after meals to minimize GI distress.
- Inspect I.V. form for particles and discoloration before administering.

**WARNING** Avoid rapid I.V. injection because it may cause cardiac arrest, CNS depression, or severe hypotension.

- To decrease vein irritation, follow I.V. injection with flush of sodium chloride for injection through same I.V. catheter.

- Continuously monitor blood pressure and ECG tracings when administering I.V. phenytoin. Be aware that bradycardia and cardiac arrest have occurred in patients receiving recommended dosages, in addition to patients experiencing phenytoin toxicity. Most cases of cardiac arrest occurred in patients with underlying cardiac disease.
- Frequently assess I.V. site for signs of extravasation because drug can cause tissue necrosis.

**WARNING** Monitor patient closely for hypersensitivity to phenytoin therapy. Know that angioedema may occur. If patient develops facial, perioral, or upper airway swelling, drug should be discontinued immediately and supportive emergency care provided.

- Know that if patient has an NG tube in place, drug absorption by polyvinyl chloride tubing can be minimized by diluting suspension threefold with sodium chloride for injection, D<sub>5</sub>W, or sterile water. After administration, flush tube with at least 20 ml diluent.
- Do not administer phenytoin concomitantly with an enteral feeding because feeding may lower phenytoin serum levels.
- Expect continuous enteral feedings to disrupt phenytoin absorption and, possibly, reduce blood phenytoin level. Discontinue tube feedings 1 to 2 hours before and after phenytoin administration, as prescribed. Anticipate giving increased phenytoin doses to compensate for reduced bioavailability during continuous tube feedings.
- Monitor phenytoin level. Therapeutic level ranges from 10 to 20 mcg/L. Expect to monitor phenytoin serum levels based on the unbound fraction in patients with hepatic or renal disease or those with hypoalbuminemia because the fraction of unbound phenytoin is increased in these patients.
- Monitor patient closely for above therapeutic levels because high serum levels that are sustained may cause cerebellar atrophy (rare), delirium, encephalopathy, irreversible cerebellar dysfunction, or psychosis. Expect to obtain serum levels if early signs of dose-related CNS toxicity develops in any patient because some patients may be slow metabolizers of phenytoin. If above therapeutic range levels are found, expect phenytoin dosage to be reduced. If symptoms persist, expect drug to be discontinued.

**WARNING** Monitor patient's hematologic status during therapy because phenytoin can cause blood dyscrasias.

A patient with a history of agranulocytosis, leukopenia, or pancytopenia may have an increased risk of infection because phenytoin can cause myelosuppression.

- Anticipate that drug may worsen intermittent porphyria.

**WARNING** Monitor patient for serious skin reactions. Onset usually occurs within 28 days but can occur later. Notify prescriber at the first sign of rash and expect phenytoin to be discontinued, unless rash is clearly not drug related. Also, expect patient with rash to be evaluated for severe cutaneous adverse reactions, which can be fatal.

- Frequently monitor blood glucose level of patient with diabetes mellitus because drug can stimulate glucagon secretion and impair insulin secretion, either of which can raise blood glucose level.
- Monitor thyroid hormone levels in patient receiving thyroid replacement therapy because phenytoin may decrease circulating thyroid hormone levels and increase thyroid-stimulating hormone level. Also know that drug may decrease dexamethasone or metyrapone test results or increase serum levels of alkaline phosphatase, gamma glutamyl transpeptidase (GGT), or glucose.
- Be aware that long-term phenytoin therapy may increase patient's requirements for folic acid or vitamin D supplements. However, keep in mind that a diet high in folic acid may decrease seizure control.
- Monitor patient closely for evidence of suicidal thinking or behavior, especially when therapy starts or dosage changes.
- Know that phenytoin should not be stopped abruptly as status epilepticus may occur. Instead, expect drug to be discontinued gradually.

## PATIENT TEACHING

- Instruct patient to crush or thoroughly chew phenytoin chewable tablets before swallowing or to shake oral solution well.
- Advise patient to take drug exactly as prescribed; she should not change brands, dosage, or stop taking drug unless instructed by prescriber.

- Instruct patients to use an accurately calibrated measuring device when using suspension form. Remind patient that a household teaspoon or tablespoon is not such a device.
- Tell patient to report any signs of heart dysfunction such as dizziness, feeling heart skipping beats, slow pulse, or tiredness.

**WARNING** Instruct patient to stop taking phenytoin immediately and seek emergency help if signs of facial, perioral, or upper airway swelling occurs.

- Urge patient to avoid alcohol during therapy.
- Caution patient to avoid hazardous activities until drug's CNS effects are known.
- Inform patient with diabetes mellitus about the increased risk of hyperglycemia and the possible need for increased antidiabetic drug dosage during therapy. Advise her to check blood glucose level often.
- Emphasize the importance of good oral hygiene, and encourage patient to inform her dentist that she's taking phenytoin.
- Encourage patient to wear medical identification that indicates her diagnosis and drug therapy.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes, and to report concerns at once to prescriber.

**WARNING** Instruct patient to notify prescriber at the first sign of a rash or if persistent, severe, or other unusual skin reactions occur.

- Inform women of childbearing age to notify prescriber immediately if pregnancy is suspected or occurs, as phenytoin may cause fetal harm.

**pimavanserin**

**Nuplazid**

## Class and Category

*Pharmacologic class:* Serotonin 5-HT receptor inverse agonist and antagonist

*Therapeutic class:* Atypical antipsychotic

## Indications and Dosages

- *To treat delusions and hallucinations associated with Parkinson's disease psychosis*

### **TABLETS**

**Adults.** 34 mg (two 17-mg tablets) once daily.

***DOSAGE ADJUSTMENT*** For patients taking strong CYP3A4 inhibitors such as ketoconazole concurrently, dosage reduced to 10 mg once daily.

## Mechanism of Action

Precise mechanism is unknown, but possibly mediates through a combination of inverse agonist and antagonist activity at serotonin 5-HT<sub>2A</sub> receptors and to a lesser extent at serotonin 5-HT<sub>2C</sub> receptors to eradicate delusions and hallucinations associated with Parkinson's disease psychosis.

## Contraindications

Hypersensitivity to pimavanserin or its components

## Interactions

## DRUGS

*antibiotics such as gatifloxacin, moxifloxacin; antipsychotics such as chlorpromazine, thioridazine, ziprasidone; class 1A antiarrhythmics such as disopyramide, procainamide, quinidine; class 3 antiarrhythmics such as amiodarone, sotalol: Possible prolonged QT interval, increasing risk of cardiac arrhythmias carbamazepine, efavirenz, modafinil, nafcillin phenytoin, rifampin, St. John's wort, thioridazine: Possibly reduced pimavanserin exposure, resulting in decreased effectiveness clarithromycin, itraconazole, ketoconazole, indinavir: Increased pimavanserin exposure, leading to possible adverse reactions*

## Adverse Reactions

**CNS:** Aggression, agitation, confusion, fatigue, gait disturbance, hallucination, somnolence

**CV:** Peripheral edema, **QT prolongation interval**

**EENT:** Circumoral edema, **throat tightness**, tongue swelling

**GI:** Constipation, nausea

**GU:** UTI

**RESP:** Dyspnea

**SKIN:** Rash, urticaria

**Other:** **Angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Keep in mind that pimavanserin shouldn't be used to treat dementia-related psychosis in the elderly, because of an increased mortality risk.
- Know that pimavanserin therapy should be avoided in patients with a history of cardiac arrhythmias, known QT prolongation, or in combination with other drugs known to prolong the QT interval. Drug should also not be used in patients who are at risk for hypokalemia or hypomagnesemia or in the presence of congenital prolongation of the QT interval or symptomatic bradycardia. Monitor patient's EKG regularly for evidence of QT prolongation.
- Use cautiously in patients with renal impairment, including severe impairment and end-stage renal disease.

**WARNING** Monitor patient for evidence of a hypersensitivity reaction that could include angioedema, rash, or urticaria. If present, notify prescriber, expect drug to be discontinued, and provide supportive care, as needed and prescribed.

## PATIENT TEACHING

- Tell patient or family to stop pimavanserin therapy and notify prescriber if an allergic reaction occurs. If reaction is severe, urge patient to seek immediate emergency medical care.
- Instruct patient or family to alert all prescribers to pimavanserin therapy and not to take any over-the-counter drugs (including herbal preparations) without prescriber knowledge.

# pioglitazone hydrochloride

**Actos**

## Class and Category

*Pharmacologic class:* Thiazolidinedione

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *To achieve glucose control in type 2 diabetes mellitus as monotherapy or in combination with insulin, metformin or a sulfonylurea*

### **TABLETS**

**Adults.** *Initial:* 15 or 30 mg daily, increased as needed to maximum dose.

*Maximum:* 45 mg daily.

***DOSAGE ADJUSTMENT*** For patients with congestive heart failure, starting dose is 15 mg once daily. For patients receiving concomitant gemfibrozil or other strong CYP2C8 inhibitors, maximum dose should not exceed 15 mg once daily. For patients taking insulin, insulin dosage decreased by 10% to 25%, as prescribed, once glucose level reaches 100 mg/dl or less. If hypoglycemia occurs, dosage of any concurrent antidiabetic reduced, as prescribed.

## Mechanism of Action

Decreases insulin resistance by enhancing the sensitivity of insulin-dependent tissues, such as adipose tissue, the liver, and skeletal muscle, and reduces glucose output from the liver. Drug activates peroxisome proliferator-activated receptor-gamma (PPAR $\gamma$ ) receptors, which modulate transcription of insulin-responsive genes involved in glucose control and lipid metabolism. In this way, pioglitazone reduces hyperglycemia, hyperinsulinemia, and hypertriglyceridemia in patients with type 2 diabetes mellitus and insulin resistance. However, to work effectively, pioglitazone needs endogenous insulin. Unlike sulfonylureas, it doesn't increase pancreatic insulin secretion.

## Contraindications

Hypersensitivity to pioglitazone or its components, New York Heart Association (NYHA) Class III or IV heart failure

## Interactions

### DRUGS

*gemfibrozil and other strong CYP2C8 inhibitors:* Increased pioglitazone effect

*insulin, oral antidiabetic agents:* Possibly increased risk of hypoglycemia

*ketoconazole:* Possibly decreased metabolism of pioglitazone

*rifampin or other CYP2C8 inducers:* Possibly altered glucose control

*topiramate:* Decreased exposure of pioglitazone and its active metabolites

## Adverse Reactions

**CNS:** Headache

**CV:** **Congestive heart failure**, edema

**EENT:** Blurred vision, decreased visual acuity, macular edema, pharyngitis, sinusitis, tooth disorders

**GI:** Elevated liver enzymes, jaundice

**HEME:** Decreased hemoglobin level and hematocrit

**MS:** Fractures, myalgia

**RESP:** Upper respiratory tract infection

**Other:** Weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Be aware that drug may result in ovulation in some anovulatory women, which increases the risk of an unintended pregnancy.

## Nursing Considerations

- Be aware that pioglitazone isn't recommended for patients with symptomatic heart failure. It is also not recommended in patients with active bladder cancer because there is insufficient information regarding the drug's role in promoting bladder tumors and should only be used with extreme caution in patients with a history of bladder cancer.

- Be prepared to monitor liver enzymes before therapy begins, every 2 months during first year, and annually thereafter, as ordered, because drug is extensively metabolized in the liver. Expect to stop drug if jaundice develops or ALT values exceed 2.5 times normal.

**WARNING** Monitor patient for signs and symptoms of congestive heart failure—such as edema, rapid weight gain, or shortness of breath—because pioglitazone can cause fluid retention that may lead to or worsen heart failure. Notify prescriber immediately of any deterioration in the patient’s cardiac status, and expect to discontinue the drug, as ordered.

- Assess for signs and symptoms of hypoglycemia, especially if patient is also taking another antidiabetic drug.
- Monitor fasting glucose level, as ordered, to evaluate effectiveness of therapy.
- Monitor glycosylated hemoglobin level to assess drug’s long-term effectiveness.

## **PATIENT TEACHING**

- Emphasize the need for patient to continue, diet control, exercise program, and weight management during pioglitazone therapy.
- Advise patient to notify prescriber immediately if she experiences fluid retention, shortness of breath, or sudden weight gain because drug may have to be discontinued.
- Urge patient to report vision changes promptly and expect to have an eye examination by an ophthalmologist, regardless of when the last examination occurred.
- Instruct patient to keep laboratory appointments for liver enzymes, as ordered, typically every 2 months during first year of therapy and annually thereafter.
- Inform female patient that she may be at risk for fractures during pioglitazone therapy, and urge her to take safety precautions to prevent falls and other injuries.

# pitavastatin calcium

**Livalo**

# pitavastatin magnesium

**Zypitamag**

## Class and Category

*Pharmacologic class:* HMG-CoA reductase inhibitor (statin)

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *As adjunct to diet in patients with primary hyperlipidemia or mixed dyslipidemia*

### **TABLETS (LIVALO, ZYPITAMAG)**

**Adults.** *Initial:* 2 mg once daily, increased as needed.

*Maximum:* 4 mg once daily

***DOSAGE ADJUSTMENT*** For patients with moderate to severe renal impairment (glomerular filtration rate 30 to 59 ml/min) or patients receiving dialysis, initial dosage reduced to 1 mg once daily, with maximum of 2 mg once daily. For patients taking erythromycin, dosage shouldn't exceed 1 mg daily; for patients taking rifampin, dosage shouldn't exceed 2 mg daily.

- *To treat heterozygous familial hypercholesterolemia to reduce total cholesterol, low-density lipoprotein cholesterol, and apolipoprotein B*

## TABLETS (LIVALO)

**Children age 8 years and older.** *Initial:* 2 mg once daily.  
*Maximum:* 4 mg once daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

## Mechanism of Action

Reduces plasma cholesterol and lipoprotein levels by inhibiting cholesterol and HMG-CoA reductase synthesis in the liver. Consequently, number of LDL receptors on liver cells increases, and LDL uptake and breakdown are enhanced. With sustained inhibition of cholesterol synthesis in the liver, levels of very low-density lipoproteins are decreased.

## Contraindications

Active liver disease (including unexplained persistent hepatic transaminase elevation), breastfeeding, concurrent cyclosporine therapy, hypersensitivity to pitavastatin or its components pregnancy.

## Interactions

### DRUGS

*colchicine, fibrates such as gemfibrozil:* Increased risk of myopathy, including rhabdomyolysis

*cyclosporine, erythromycin, rifampin:* Increased pitavastatin exposure; increased risk of myopathy and rhabdomyolysis

*niacin:* Increased risk of adverse skeletal muscle effects

## ACTIVITIES

*alcohol*: Increased risk of liver injury with heavy use

## Adverse Reactions

**CNS**: Asthenia, confusion, cognitive impairment, depression, dizziness, fatigue, headache, hypoesthesia, insomnia, malaise, memory loss, peripheral neuropathy

**EENT**: Nasopharyngitis

**ENDO**: Elevated glycosylated hemoglobin level, hyperglycemia

**GI**: Abdominal discomfort or pain, constipation, diarrhea, dyspepsia, elevated liver enzymes, **hepatic failure**, **hepatitis**, jaundice, nausea

**GU**: **Acute renal failure**, erectile dysfunction, **myoglobinuria**

**MS**: Arthralgia, back or extremity pain, **immune-mediated necrotizing myopathy** (rare), muscle spasms, myopathy, myositis, **rhabdomyolysis**

**RESP**: **Interstitial lung disease**

**SKIN**: Pruritus, rash, urticaria

**Other**: **Angioedema**, elevated creatine phosphokinase level, flu-like symptoms

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in pregnant women and should be discontinued as soon as pregnancy is known.

### LACTATION

- It is not known if drug is present in breast milk.
- Drug is contraindicated for use in women who are breastfeeding.

## **REPRODUCTION**

- Advise females of childbearing age to use effective contraception during drug therapy.

## **Nursing Considerations**

- Note that pravastatin, another HMG-CoA reductase inhibitor, sounds similar to pitavastatin and could be confusing. Make sure of correct drug before giving.
- Monitor liver enzymes, as ordered, before pravastatin therapy starts and as indicated during therapy. Know that patients who drink alcohol heavily and/or have a history of liver disease may be at increased risk for liver injury.
- Use pitavastatin cautiously in patients with risk factors for myopathy, such as concurrent use of colchicine, niacin-containing products (greater than 1 g daily), or fibrates and that cyclosporine is a contraindication and gemfibrozil not recommended during pitavastatin therapy. Additional risk factors include the elderly (over age 65), presence of renal impairment, or in patients who are being inadequately treated for hypothyroidism. Monitor patient throughout therapy for muscular complaints and an elevated blood creatine kinase level. Drug should be discontinued if patient's creatine kinase level becomes markedly elevated, or if myopathy is suspected or confirmed.
- Although rare, immune-mediated necrotizing myopathy has been associated with statin therapy. Monitor patient for elevated serum creatine kinase levels and proximal muscle weakness, which persists despite discontinuation of the statin. Patient may need immunosuppressive therapy.
- Expect to monitor patient's lipid levels after 4 weeks of therapy to determine drug effectiveness and periodically thereafter, as ordered. Expect dosage to be adjusted if lipid levels remain elevated.
- Monitor patient's blood glucose levels and HbA1c in patients with diabetes because pitavastatin as a statin may increase blood glucose levels and alter control.

## PATIENT TEACHING

- Emphasize that pitavastatin is an adjunct to, not a substitute for, a low-cholesterol diet.
- Tell patient to take drug at the same time each day to maintain its effects.
- Instruct patient to report unexplained muscle pain, tenderness, or weakness, especially if accompanied by fever or malaise.
- Advise patient to limit alcohol ingestion while taking pitavastatin because alcohol-induced liver dysfunction may be difficult to differentiate from pitavastatin-induced liver dysfunction.
- Instruct patient to consult prescriber before taking OTC niacin products because of increased risk of adverse muscle effects.
- Caution women of childbearing age that drug is contraindicated in pregnancy because drug could be harmful to the baby. If pregnancy is suspected, patient should notify prescriber immediately.
- Advise women not to breastfeed during pitavastatin therapy.
- Inform patient, especially diabetics, that pitavastatin may increase blood glucose levels and alter their control. Encourage patient to monitor their blood glucose levels closely throughout pitavastatin therapy.

**plazomicin**

**Zemdri**

## Class and Category

*Pharmacologic class:* Aminoglycoside

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat complicated urinary tract infections, including pyelonephritis, caused by Enterobacter cloacae, Escherichia coli, Klebsiella pneumoniae, or Proteus mirabilis*

## **I.V. INFUSION**

**Adults and adolescents age 18 and over who have a creatinine clearance greater than or equal to 90 ml/min.** 15 mg/kg infused over 30 min every 24 hr for 4 to 7 days.

***DOSAGE ADJUSTMENT*** For patient with a creatinine clearance less than 90 ml/min but equal to or greater than 60 ml/min, dosage remains at 15 mg/kg every 24 hr. For patient with a creatinine clearance less than 60 ml/min but greater than or equal to 30 ml/min, dosage reduced to 10 mg/kg every 24 hr. For patient with a creatinine clearance less than 30 ml/min but greater than or equal to 15 ml/min, dosage reduced to 10 mg/kg and dosage interval increased to every 48 hr.

## **Mechanism of Action**

Binds to bacterial 30S ribosomal subunit to inhibit protein synthesis, which exerts a bactericidal effect.

## **Incompatibilities**

Do not mix plazomicin with other drugs or physically add to solutions containing other drugs, and do not infuse other drugs simultaneously with plazomicin, because incompatibilities are unknown.

## **Contraindications**

Hypersensitivity to plazomicin, other aminoglycosides, or their components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**CNS:** Dizziness, headache, vertigo

**CV:** Hypertension, **hypotension**

**EENT:** Hearing loss, ototoxicity, tinnitus

**GI:** *Clostridium difficile*-associated diarrhea, constipation, diarrhea, elevated liver enzymes, gastritis, nausea, vomiting

**GU:** Elevated serum creatinine, hematuria, impaired renal function, **nephrotoxicity**

**RESP:** Dyspnea

**Other:** **Hypersensitivity reactions, hypokalemia**

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Expect to assess creatinine clearance in all patients prior to first dose of plazomicin and daily during therapy. For patients with renal impairment with a creatinine clearance of 15 ml/min or greater but less than 90 ml/min, expect plasma trough concentrations to be below 3 mcg/ml. Plasma trough level should be measured about 30 min before administration of second dose. If level is greater than or equal to 3 mcg/ml, expect a dosage adjustment to be made by extending the dosing interval by 1.5-fold; for example, from every 24 hours to every 36 hours or from every 48 hours to every 72 hours. Know that patients at greater risk for nephrotoxicity are the elderly, patients with existing impaired renal function, and those who are receiving concomitant nephrotoxic drugs.
- Know that each drug vial contains 500 mg plazomicin freebase in 10 ml Water for Injection, giving a concentration of 50 mg/ml. Dilute drug vial solution in 0.9% sodium chloride injection, USP, or Lactated Ringer's Injection, USP, to achieve a final volume of 50 ml for intravenous infusion. After dilution, drug solution is stable for 24 hours at room temperature. Infuse each dose over 30 minutes.
- Monitor patient for hearing loss, tinnitus, and/or vertigo, because plazomicin may cause ototoxicity that may be irreversible and may not show up until after drug has been discontinued. Patients at higher risk include those with a family history of hearing loss, already have renal impairment, or are receiving higher doses and/or longer durations of therapy than recommended.

**WARNING** Monitor patient for adverse reactions associated with neuromuscular blockade, because aminoglycosides such as plazomicin have been associated with neuromuscular blockade. Patients at high risk include patients with underlying neuromuscular disorders (including myasthenia gravis) or patients who are receiving concomitantly neuromuscular blocking drugs.

**WARNING** Monitor patient for hypersensitivity reactions. Aminoglycosides have occasionally caused serious allergic reactions. Notify prescriber immediately and expect plazomicin to be discontinued. Provide supportive care, as ordered and needed.

- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold plazomicin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.

## PATIENT TEACHING

- Tell patient that it is important to keep hydrated during plazomicin therapy, because dehydration increases the risk of kidney impairment.
- Alert patient that diarrhea is a common problem with antibacterial drugs. Tell patient that bloody or watery stools can occur even after plazomicin therapy has been discontinued. Stress importance of reporting diarrhea to prescriber.
- Instruct patient to report any adverse reactions that might indicate an allergic reaction (such as hives, itching, and rash), because an allergic reaction can become serious.
- Tell patient to report any changes in balance or hearing or if she experiences new onset or changes in preexisting buzzing or roaring in the ears, even after the course of plazomicin therapy has finished.
- Warn women of childbearing age to notify prescriber immediately if pregnancy is suspected or known, because aminoglycosides such as plazomicin can cause fetal harm.
- Inform patient with an underlying neuromuscular disease or patient who is receiving neuromuscular blocking agents that aggravation of muscle weakness has been reported with other aminoglycosides. Tell patient to report any muscle weakness that is abnormal for him to prescriber.

**plecanatide**

**Trulance**

## Class and Category

*Pharmacologic class:* Guanylate cyclase-C agonist

*Therapeutic class:* Intestinal mobility agent

## Indications and Dosages

- *To treat chronic idiopathic constipation or irritable bowel syndrome with constipation*

### **TABLETS**

**Adults.** 3 mg once daily.

## Mechanism of Action

Acts locally on the luminal surface of the intestinal epithelium, resulting in an increase in both extracellular and intracellular concentrations of cyclic guanosine monophosphate (cGMP). Elevation of intracellular cGMP stimulates secretion of bicarbonate and chloride into the intestinal lumen. This increases intestinal fluid and accelerates transit time, which relieves constipation.

## Contraindications

Children less than 6 years of age, hypersensitivity to plecanatide or its components, known or suspected mechanical gastrointestinal obstruction.

## Interactions

### **DRUGS**

None reported

## Adverse Reactions

**CNS:** Dizziness

**EENT:** Nasopharyngitis, sinusitis

**GI:** Abdominal distention or tenderness, diarrhea, flatulence, elevated liver enzymes, nausea

**GU:** UTI

**RESP:** Upper respiratory tract infection

**Other:** Dehydration

## **Childbearing Considerations**

### **PREGNANCY**

- Drug is negligibly absorbed systemically following oral administration so drug exposure to fetus is minimal. However, it is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LACTATION**

- It is not known if drug is present in breast milk.
- Be aware that exposure to drug in breastfed infants has the potential for serious adverse reactions.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Be aware that plecanatide therapy should be avoided in patients 6 years to less than 18 years of age and is contraindicated in patients who are less than 6 years of age because of the potential for serious dehydration from plecanatide use.
- Administer plecanatide in applesauce or water if patient has difficulty swallowing tablets whole. To administer in applesauce, crush tablet to a powder and mix with 1 teaspoon of room-temperature applesauce. Administer immediately. Do not store mixture for later use. To administer

in water, place tablet in cup, add 30 ml of room-temperature water and gently swirl tablet and water mixture for at least 10 seconds. Have patient swallow entire contents of tablet/water mixture immediately. If any portion of the tablet is left in the cup, add another 30 ml of room-temperature water to the cup, swirl for at least 10 seconds, and have patient swallow the mixture immediately. Do not store the tablet/water mixture for later use.

- Know that plecanatide may be administered via a gastric or nasogastric feeding tube. Begin by placing plecanatide tablet in a cup; then add 30 ml of room-temperature water. Gently swirl the tablet and water mixture for at least 15 seconds. Flush the feeding tube with 30 ml of water. Draw up the drug mixture using the syringe and immediately administer via the feeding tube. Do not reserve for future use. If any portion of the tablet is left in the cup, add another 30 ml of room-temperature water, swirl for at least 15 seconds. Using the same syringe, administer via the feeding tube. Follow by flushing the feeding tube with at least 10 ml of water.
- Monitor patient for diarrhea, which can become severe. If severe diarrhea occurs, withhold drug. Notify prescriber and expect to follow measures to rehydrate patient, as ordered.

## **PATIENT TEACHING**

- Caution patient not to exceed dosage, as severe dehydration may occur.
- Instruct patient to swallow tablet whole. If patient is unable to swallow tablet, tell patient how to mix in applesauce or room-temperature water. Warn patient to take mixture immediately and not to store for later use.
- Tell patient to store plecanatide in a dry place and protect from moisture. Also remind patient to keep drug in original bottle, with desiccant in the bottle, and not subdivide or repack drug in any way. Instruct patient to keep bottle tightly closed when not in use.
- Tell patient to stop taking drug and notify prescriber if severe diarrhea occurs.
- Warn patient to keep plecanatide out of the reach of children, especially those who are less than 6 years of age.
- Tell patient if she misses a dose, she should skip the missed dose and take the next dose at the regular time. She should never double the dose.

# posaconazole

**Noxafil**

## Class and Category

*Pharmacologic class:* Triazole

*Therapeutic class:* Antifungal

## Indications and Dosages

- *To prevent invasive Aspergillus and candida infections in patients at high risk because of severe immunocompromise from such conditions as graft-versus-host disease with hematopoietic stem-cell transplant or hematologic malignancies with prolonged neutropenia from chemotherapy*

### ORAL SUSPENSION

**Adults and adolescents.** 200 mg (5 ml) three times a day until recovery from immunosuppression or neutropenia.

### DELAYED RELEASE TABLETS

**Adults and adolescents.** *Initial:* 300 mg twice daily on first day, followed by 300 mg once daily starting on second day until recovery from immunosuppression or neutropenia.

### I.V. INFUSION

**Adults.** *Initial:* 300 mg infused over 90 min via a central venous line twice daily on first day, followed by 300 mg infused over 90 min via a central venous line once daily starting on second day until recovery from neutropenia or immunosuppression.

➤ *To treat oropharyngeal candidiasis*

## ORAL SUSPENSION

**Adults.** *Initial:* 100 mg (2.5 ml) twice daily on first day, followed by 100 mg (2.5 ml) once daily for 13 days.

➤ *To treat oropharyngeal candidiasis refractory to fluconazole and/or itraconazole*

## ORAL SUSPENSION

**Adults.** 400 mg (10 ml) twice daily until underlying condition improves.

Route	Onset	Peak	Duration
P.O.	Unknown	3-5 hr	Unknown
I.V.	Unknown	Unknown	Unknown

## Mechanism of Action

Blocks synthesis of ergosterol, an essential component of fungal cell membrane, by inhibiting 14 alpha-demethylase, an enzyme needed for conversion of lanosterol to ergosterol. Lack of ergosterol increases cellular permeability, and cell contents leak.

## Incompatibilities

Do not dilute posaconazole in any solution other than 5% dextrose in water or 0.9% sodium chloride. The following

drugs may be infused at the same time through the same cannula or intravenous line with posaconazole: amikacin, caspofungin, ciprofloxacin, daptomycin, dextrose in water 5%, dobutamine, famotidine, filgrastim, gentamicin, hydromorphone, levofloxacin, lorazepam, meropenem, micafungin, morphine sulfate, norepinephrine bitartrate, potassium chloride, sodium chloride 0.9%, and vancomycin. All other drugs and solutions may result in particulate formation and should not be coadministered through the same cannula or intravenous line.

## Contraindications

Concurrent therapy with atorvastatin, lovastatin, simvastatin, sirolimus; hypersensitivity to posaconazole, its components, or other azole antifungals; use with ergot alkaloids or CYP3A4 substrates such as pimozide and quinidine

## Interactions

### DRUGS

*alprazolam, midazolam, triazolam*: Increased plasma levels of these drugs which could potentiate and prolong hypnotic and sedative effects

*calcium channel blockers (diltiazem, felodipine, nicardipine, nifedipine, verapamil)*: Increased plasma concentrations of these drugs with increased risk of adverse reactions

*cimetidine (oral suspension only), efavirenz, esomeprazole (oral suspension only), fosamprenavir, metoclopramide (oral suspension only), phenytoin, rifabutin*: Possibly decreased plasma level of posaconazole

*cyclosporine, tacrolimus*: Increased plasma levels of these drug, with increased risk of adverse reactions

*digoxin*: Increased risk of digitalis toxicity

*ergot alkaloids*: Increased plasma ergot alkaloid level and increased risk of ergotism

*HMG-CoA reductase inhibitors*: Increased plasma statin level and increased risk of rhabdomyolysis

*pimozide, quinidine*: Increased plasma concentrations of these drugs, leading to QT prolongation and torsades de pointes

*sirolimus*: Increased sirolimus blood concentration with possible sirolimus toxicity

*vinca alkaloids*: Increased plasma vinca alkaloid level and increased risk of neurotoxicity

## Adverse Reactions

**CNS**: Anxiety, asthenia, dizziness, fatigue, fever, headache, insomnia, rigors, tremor, weakness

**CV**: Edema, hypertension, **hypotension**, **QT-interval prolongation**, tachycardia

**EENT**: Blurred vision, epistaxis, herpes simplex, mucositis, pharyngitis, taste perversion

**ENDO**: Hyperglycemia, pseudoaldosteronism

**GI**: Abdominal pain, anorexia, bilirubinemia, constipation, diarrhea, dyspepsia, elevated liver enzymes, hepatomegaly, jaundice, nausea, **pancreatitis**, vomiting

**GU**: **Acute renal failure**, elevated blood creatinine level, vaginal hemorrhage

**HEME**: Anemia, **neutropenia**, **thrombocytopenia**

**MS**: Arthralgia, back or musculoskeletal pain

**RESP**: Coughing, dyspnea, pneumonia, upper respiratory tract infection

**SKIN**: Diaphoresis, petechiae, pruritus, rash

**Other:** **Bacteremia**, cytomegalovirus infection, dehydration, **hypocalcemia**, **hypokalemia**, **hypomagnesemia**, weight loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use cautiously in patients who have had a hypersensitivity reaction to other azoles because of risk for cross-sensitivity.
- Use cautiously in patients with hepatic or renal dysfunction. Know that posaconazole injection should be avoided, if possible, in patients with moderate or severe renal impairment (GFR less than 50 ml/min). If not possible, expect to monitor serum creatinine levels, as ordered, and if increases occur, anticipate patient being switched to oral posaconazole therapy.
- Use cautiously in patients with potentially proarrhythmic conditions because posaconazole may prolong QT interval.
- Expect to obtain electrolytes and correct any disturbances, as prescribed before and routinely during posaconazole therapy.
- Obtain baseline assessment of liver function and check periodically during therapy, as ordered. If elevations occur or patient has evidence of elevated liver enzymes, notify prescriber.

- Shake oral suspension well before administering. Use only the spoon provided in the package to measure dosage. Each dose should be administered during or immediately following (within 20 minutes) a full meal to enhance absorption. If patient cannot eat a full meal, administer drug with an acidic carbonated beverage or a liquid nutritional supplement.
- Administer delayed-release tablets with food.
- Do not interchange delayed-release tablet and oral suspension because of differences in the dosing of each formulation.
- Prepare parenteral form of posaconazole by first removing vial from refrigerator and allowing it to warm to room temperature. Transfer 16.7 ml of the drug solution to an intravenous bag or bottle containing about 150 ml of 5% dextrose in water or 0.9% sodium chloride. Once mixed, use immediately, or refrigerate for up to 24 hours. Discard any unused solution.
- Administer parenteral form of drug through a 0.22-micron polyethersulfone (PES) or polyvinylidene difluoride (PVD) filter using a central venous line by slow infusion over 90 minutes. Never administer drug by bolus injection. If a central venous line is not available, drug may be administered through a peripheral venous catheter only as a single dose in advance of a central venous line being placed or to bridge the period during which a central venous line is replaced or is in use for other treatment. When administering the drug through a peripheral venous catheter, infuse the drug over 30 minutes.
- Monitor patient experiencing severe diarrhea or vomiting for breakthrough fungal infections.

## **PATIENT TEACHING**

- Advise patient prescribed oral suspension form to use the measuring spoon supplied by manufacturer and to rinse it with water after each use.
- Instruct patient to take posaconazole oral suspension with or within 20 minutes after a full meal or liquid nutritional supplement to increase drug absorption. Tell patient that he also may take posaconazole with an acidic carbonated beverage such as ginger ale.
- Advise patient prescribed delayed-release tablets to take with food; to swallow tablets whole; and to not chew, crush, or divide tablets.
- Tell patient to report severe diarrhea or vomiting because these conditions may interfere with drug effectiveness.

- Instruct patient to alert prescriber if he is already taking vinblastine, vincristine, or any other vinca alkaloids used to treat cancer.

## **potassium acetate**

***(contains 2 or 4 mEq of elemental potassium per 1 ml of injection)***

potassium per 5 ml of oral solution)***

# Tri-K

## Class and Category

*Pharmacologic class:* Electrolyte cation

*Therapeutic class:* Electrolyte replacement

## Indications and Dosages

- *To prevent or treat hypokalemia in patients who can't ingest sufficient dietary potassium or who are losing potassium because of a condition (such as hepatic cirrhosis or prolonged vomiting) or drug (such as potassium-wasting diuretics or certain antibiotics)*

### **EFFERVESCENT TABLETS (POTASSIUM BICARBONATE)**

**Adults and adolescents.** 25 to 50 mEq/g once or twice daily, as needed and tolerated.

*Maximum:* 100 mEq daily.

### **EFFERVESCENT TABLETS (POTASSIUM BICARBONATE AND POTASSIUM CHLORIDE)**

**Adults and adolescents.** 20, 25, or 50 mEq once or twice daily, as needed and tolerated. *Maximum:* 100 mEq daily.

### **EFFERVESCENT TABLETS (POTASSIUM BICARBONATE AND POTASSIUM CITRATE)**

**Adults and adolescents.** 25 or 50 mEq once or twice daily, as needed and tolerated.

*Maximum:* 100 mEq daily.

## **ELIXIR (POTASSIUM GLUCONATE)**

**Adults and adolescents.** 20 mEq twice daily to four times daily, as needed and tolerated. *Maximum:* 100 mEq daily.

**Children.** 2 to 3 mEq/kg daily in divided doses.

## **E.R. CAPSULES (POTASSIUM CHLORIDE)**

**Adults and adolescents.** 40 to 100 mEq daily in divided doses twice daily or three times a day for treatment; 16 to 24 mEq daily in divided doses twice daily or three times a day for prevention. *Maximum:* 100 mEq daily.

## **E.R. TABLETS (POTASSIUM CHLORIDE)**

**Adults and adolescents.** 6.7 to 20 mEq three times a day. *Maximum:* 100 mEq daily.

## **GRANULE PACKETS (POTASSIUM BICARBONATE AND POTASSIUM CHLORIDE)**

**Adults and adolescents.** 20 mEq once or twice daily, as needed and tolerated.

*Maximum:* 100 mEq daily.

## **GRANULES FOR ORAL SUSPENSION (POTASSIUM CHLORIDE)**

**Adults and adolescents.** 20 mEq 1 to 5 times/day, as needed. *Maximum:* 100 mEq daily.

## **ORAL SOLUTION (POTASSIUM CHLORIDE)**

**Adults and adolescents.** 20 mEq once daily to four times a day, as needed and tolerated. *Maximum:* 100 mEq daily.

**Children.** 1 to 3 mEq/kg daily in divided doses.

## **ORAL SOLUTION (POTASSIUM GLUCONATE AND POTASSIUM CHLORIDE, POTASSIUM GLUCONATE AND POTASSIUM CITRATE)**

**Adults and adolescents.** 20 mEq twice daily to four times a day, as needed and tolerated. *Maximum:* 100 mEq daily.

**Children.** 2 to 3 mEq/kg daily in divided doses.

## **POWDER PACKET FOR ORAL SOLUTION (POTASSIUM CHLORIDE)**

**Adults.** 15 to 25 mEq twice daily to four times a day, as needed and tolerated. *Maximum:* 100 mEq daily.

**Children.** 1 to 3 mEq/kg daily in divided doses, as needed and tolerated.

## **POWDER PACKET FOR ORAL SOLUTION (POTASSIUM GLUCONATE AND POTASSIUM CHLORIDE)**

**Adults and adolescents.** 20 mEq twice daily to four times a day, as needed and tolerated. *Maximum:* 100 mEq daily.

**Children.** 2 to 3 mEq/kg daily in divided doses.

## **ORAL TRIKATES SOLUTION (POTASSIUM ACETATE, POTASSIUM BICARBONATE, AND POTASSIUM CITRATE)**

**Adults and adolescents.** 15 mEq three times a day to four times a day, as needed and tolerated. *Maximum:* 100 mEq daily.

**Children.** 2 to 3 mEq/kg daily in divided doses.

## **TABLETS (POTASSIUM GLUCONATE)**

**Adults and adolescents.** 5 to 10 mEq twice daily to four times a day, as needed and tolerated. *Maximum:* 100 mEq daily.

## **I.V. INFUSION (POTASSIUM ACETATE AND POTASSIUM CHLORIDE)**

**Adults and adolescents with serum potassium level above 2.5 mEq/L.** Up to 10 mEq/hr. *Maximum:* 200 mEq daily.

**Adults and adolescents with serum potassium level below 2 mEq/L, ECG changes, or paralysis.** Up to 20 mEq/hr.

*Maximum:* 400 mEq daily.

**Children.** 3 mEq/kg daily infused at a rate no greater than 0.5 mEq/kg/hr.

***DOSAGE ADJUSTMENT*** Dosage adjusted as prescribed based on patient's ECG patterns and serum potassium level.

- *To treat renal tubular acidosis with calcium stones, hypocitraturic calcium oxalate nephrolithiasis of any etiology, and uric acid lithiasis with or without calcium stones*

## **TABLETS (POTASSIUM CITRATE)**

**Adults.** For patients with severe hypocitraturia, 15 mEq four times a day with meals or 20 mEq three times a day with meals. For patients with mild to moderate hypocitraturia, 10 mEq three times a day with meals.

***DOSAGE ADJUSTMENT*** For patients with cirrhosis or renal impairment, dosage should be started at the lower end of the dosing range for all formulations of potassium.

## **Mechanism of Action**

Acts as the major cation in intracellular fluid, activating many enzymatic reactions essential for physiologic processes, including nerve impulse transmission and cardiac and skeletal muscle contraction. Potassium also helps maintain electroneutrality in cells by controlling exchange of intracellular and extracellular ions. It also helps maintain normal renal function and acid-base balance.

## **Incompatibilities**

Don't mix potassium chloride for injection in same syringe with amino acid solutions, lipid solutions, or mannitol because these drugs may precipitate from solution. Administration with blood or blood products can cause lysis of infused RBCs.

## **Contraindications**

Acute dehydration, Addison's disease (untreated), concurrent use with amiloride or triamterene (potassium chloride), or potassium-sparing diuretics (all forms of potassium), crush syndrome, disorders that may delay drug passing through GI tract (potassium citrate), heat cramps, hyperkalemia, hypersensitivity to potassium salts or their components, peptic ulcer disease (potassium citrate), renal impairment with azotemia or oliguria, severe hemolytic anemia, UTI (potassium citrate)

## **Interactions**

### **DRUGS**

*ACE inhibitors, aliskiren, amiloride, angiotensin II receptor antagonists, beta blockers, blood products,*

*corticosteroids, cyclosporine, eplerenone, heparin, NSAIDs, potassium-containing drugs, potassium-sparing diuretics, tacrolimus, triamterene:* Increased risk of hyperkalemia that can become severe

*amphotericin B, corticosteroids (glucocorticoids, mineralocorticoids), gentamicin, penicillins, polymyxin B:* Possibly hypokalemia

*anticholinergics, drugs with anticholinergic activity:* Increased risk of GI ulceration, stricture, and perforation

*antiepileptics, diuretics:* Increased risk of hyponatremia when used with high concentration of potassium chloride

*calcium salts (parenteral):* Possibly arrhythmias

*digoxin:* Increased risk of digitalis toxicity

*insulin, laxatives, sodium bicarbonate:* Decreased serum potassium level

*sodium polystyrene sulfonate:* Possibly decreased serum potassium level and fluid retention

*thiazide diuretics:* Possibly hyperkalemia when diuretic is discontinued

## **FOODS**

*low-salt milk, salt substitutes:* Increased risk of hyperkalemia

## **Adverse Reactions**

**CNS:** Chills, confusion, fever, **hyponatremic encephalopathy (with use of high concentration of potassium chloride)**, paralysis, paresthesia, weakness

**CV:** **Arrhythmias, asystole, bradycardia, cardiac arrest**, chest pain, **ECG changes**, peripheral edema, **ventricular fibrillation**

**EENT:** Throat pain when swallowing

**GI:** Abdominal pain; **bloody stools**; diarrhea; flatulence; **GI bleeding, obstruction, perforation**, or ulceration; nausea; vomiting

**RESP:** Dyspnea, **pulmonary edema (with high concentration of potassium chloride)**

**SKIN:** Rash

**Other:** **Anaphylaxis; angioedema**; extravasation reactions such as necrosis, nerve or tendon injury, ulcers, or vascular injury; **hyperkalemia**; hypervolemia (with high concentration of potassium chloride); **hypokalemia; hyponatremia (with use of high concentration of potassium chloride)**, infusion-site reactions such as burning sensation, erythema, irritation, pain, phlebitis, pruritus, rash, or **thrombosis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but may if hyperkalemia occurs.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Potassium is normally present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Review patient's medical history before administering potassium chloride, because there are many conditions that may predispose patient to develop hyperkalemia and increased sensitivity to potassium.
- Administer oral potassium with or immediately after meals.

- Mix potassium chloride for oral solution or potassium gluconate elixir in cold water, orange juice, tomato juice (if patient isn't sodium restricted), or apple juice, and stir for 1 full minute before administering.
- Mix potassium bicarbonate, potassium bicarbonate and potassium chloride, and potassium bicarbonate and potassium citrate effervescent tablets with cold water and allow to dissolve completely.
- Be aware that liquid form of oral potassium is prescribed for patients with delayed gastric emptying, esophageal compression, or intestinal obstruction or stricture, as well as patients with dysphagia or swallowing disorders, to decrease the risk of tissue damage from solid forms of potassium that may remain in contact with the gastrointestinal mucosa for a prolonged period of time.
- Administer tablet forms of potassium with food to help prevent gastric irritation. Monitor patient receiving tablet forms of potassium for abdominal pain or distention, gastrointestinal bleeding, or severe vomiting, as this may indicate GI obstruction, perforation, or ulceration and should be reported immediately.
- Be aware that potassium chloride injection should be given with extreme caution, if at all, to patients with conditions that increase patient sensitivity to potassium or predispose patient to hyperkalemia, such as acute dehydration, congestive heart failure, extensive burns or tissue injury, or severe renal impairment. Also be aware that high concentration of potassium chloride for injection should be avoided in patients at risk for hyponatremia. If use cannot be avoided, monitor patient closely.

**WARNING** Be aware that direct injection of a potassium concentrate may be immediately fatal. Dilute potassium concentrate for injection with adequate volume of solution before I.V. use. Maximum suggested concentration is 40 mEq/L, although stronger concentrations (up to 80 mEq/L) may be used for severe hypokalemia. Inappropriate solutions or improper technique may cause extravasation, fever, hyperkalemia, hypervolemia, I.V. site infection, phlebitis, venospasm, and venous thrombosis.

- Don't connect flexible plastic containers in series because of increased risk of residual air contained in the primary container that could cause an air embolism.

- Infuse potassium slowly at a controlled rate using a calibrated infusion device to avoid phlebitis and decrease risk of adverse cardiac reactions. Keep in mind that different forms of potassium salts contain different amounts of elemental potassium per gram and that not all forms are dosage equivalent. If possible, administer via a central intravenous route. Know that high concentrations of potassium chloride only should be given through a central line.
- Monitor serum potassium level before and during administration of I.V. potassium. Be aware that mild or moderate hyperkalemia is asymptomatic and may be manifested only by increased serum potassium concentrations, and possibly by characteristic ECG changes. Arrhythmias can develop at any time during hyperkalemia.

**WARNING** Be aware that some forms of potassium contain tartrazine, which may cause an allergic reaction, such as asthma. Some forms may also contain aluminum, which may become toxic in a patient with impaired renal function.

- Regularly assess patient for signs of hypokalemia, such as arrhythmias, fatigue, and weakness, and for signs of hyperkalemia, such as arrhythmias, confusion, dyspnea, and paresthesia.
- Monitor serum creatinine level and urine output during administration, because adequate renal function is needed for potassium supplementation. Notify prescriber about signs of decreased renal function, because renal impairment may predispose patient to fluid overload and/or hyperkalemia.

## PATIENT TEACHING

- Inform patient that potassium is part of a normal diet and that most meats, seafoods, fruits, and vegetables contain sufficient potassium to meet recommended daily intake. Also advise her not to exceed recommended daily amount of potassium.
- Teach patient the correct way to take prescribed potassium. This can vary from swallowing a tablet with a full glass of water to mixing certain preparations with half to full glass of cold water or juice.
- Caution patient not to crush or chew E.R. forms unless instructed otherwise.

- Instruct patient to take drug with or right after food.
- Teach patient how to take her radial pulse, and advise her to notify prescriber about significant changes in heart rate or rhythm.
- Advise patient to watch stools for changes in color and consistency and to notify prescriber if they become black, tarry, or red.
- Inform patient that although she may see waxy form of E.R. tablet in stools, she has received all of the potassium.
- Urge patient to keep follow-up laboratory appointments as directed by prescriber to determine serum potassium level.

## potassium phosphates

**K-Phos Original, Neutra-Phos-K**

## potassium and sodium phosphates

**K-Phos-Neutral, K-Phos No. 2**

## sodium phosphates

### **Class and Category**

*Pharmacologic class:* Soluble salts

*Therapeutic class:* Antiurolithic, electrolyte replenisher

### **Indications and Dosages**

- *To increase urinary phosphate and pyrophosphate for urinary acidification*

## **MONOBASIC TABLETS (POTASSIUM PHOSPHATES)**

**Adults and adolescents.** 1 g in 180 to 240 ml water four times a day, after meals and at bedtime.

## **MONOBASIC TABLETS (POTASSIUM AND SODIUM PHOSPHATES)**

**Adults and adolescents.** 250 mg in 240 ml water four times a day, after meals and at bedtime. Dosage interval may be increased to every 2 hr if urine is difficult to acidify.  
*Maximum: 2 g/24 hr.*

- *To prevent or treat hypophosphatemia*

## **CAPSULES (POTASSIUM PHOSPHATES)**

**Adults and children age 4 and over.** 1.45 g in 75 ml water or juice four times a day, after meals and at bedtime.

**Children up to age 4.** 200 mg in 60 ml water or juice four times a day, after meals and at bedtime.

## **CAPSULES (POTASSIUM AND SODIUM PHOSPHATES)**

**Adults and children age 4 and over.** 1.25 g in 75 ml water or juice four times a day, after meals and at bedtime.

**Children up to age 4.** 200 mg in 60 ml water or fruit juice four times a day, after meals and at bedtime.

## **MONOBASIC TABLETS (POTASSIUM PHOSPHATES)**

**Adults and children age 4 and over.** 1 g in 180 to 240 ml water four times a day, after meals and at bedtime.

**Children up to age 4.** 200 mg in 60 ml water four times a day, after meals and at bedtime.

## **MONOBASIC TABLETS (POTASSIUM AND SODIUM PHOSPHATES)**

**Adults and children age 4 and over.** 250 mg in 240 ml water four times a day, after meals and at bedtime.

**Children up to age 4.** 200 mg in 60 ml water four times a day, after meals and at bedtime.

## **ORAL SOLUTION (POTASSIUM PHOSPHATES, POTASSIUM AND SODIUM PHOSPHATES)**

**Adults and children age 4 and over.** 250 mg four times a day, after meals and at bedtime.

**Children up to age 4.** 200 mg four times a day, after meals and at bedtime.

## **TABLETS (POTASSIUM AND SODIUM PHOSPHATES)**

**Adults and children age 4 and over.** 250 mg in a full glass of water four times a day, after meals and at bedtime.

**Children up to age 4.** 200 mg in 60 ml water four times a day, after meals and at bedtime.

## **I.V. INFUSION (SODIUM PHOSPHATES)**

**Adults and adolescents.** 10 to 15 mmol (310 to 465 mg) daily, with the infusion rate determined by the patient's individual needs.

**Children.** 1.5 to 2 mmol (46.5 to 62 mg)/kg daily, with infusion rate determined by the needs of the individual patient.

# Mechanism of Action

Reverses symptoms of hypophosphatemia by replenishing the body's supply of phosphate; acidifies urine by causing hydrogen to be exchanged for sodium in renal distal tubule; and inhibits formation of calcium renal calculi by preventing solidification of calcium oxalate.

# Incompatibilities

Don't add phosphates to calcium- or magnesium-containing solutions because precipitate may form.

# Contraindications

Hyperkalemia (potassium formulations), hyponatremia (sodium formulations), hypersensitivity to any component of potassium phosphates, hyperphosphatemia, hypocalcemia, phosphate urolithiasis accompanied by infection, severe renal insufficiency

# Interactions

## DRUGS

*ACE inhibitors, aliskiren, angiotensin II receptor blockers, cyclosporine, drospirenone, eplerenone, heparin, nicorandil, potassium-containing drugs, potassium-sparing diuretics:* Increased risk of hyperkalemia (potassium forms only)

*alpha/beta agonists, amantadine, amphetamines, erdafitinib, mecamlamine:* Possibly decreased serum concentration of these drugs

*antacids iron salts, oral calcium salts, sucralfate:* Possibly impaired phosphate absorption

*burosumab*: Possibly enhanced the adverse/toxic effect of burosumab

*chlopropamide*: Possibly increased serum concentration of chlorpropamide

*magnesium salts, multivitamins/minerals (with ADEK, folate, iron)*: Possibly decreased serum concentration of phosphate supplements

*phosphate-containing drugs, vitamin D*: Increased risk of hyperphosphatemia

*salicylates*: Increased blood salicylate level

## **FOODS**

*salt substitutes*: Increased risk of hyperkalemia

*oxalates (in spinach and rhubarb), phytates (in bran and whole grains)*: Decreased absorption of phosphate

## **Adverse Reactions**

**CNS**: Anxiety, confusion, dizziness, fatigue, headache, paresthesia, **seizures**, tremor, weakness

**CV**: **Arrhythmias**, edema of legs, tachycardia

**GI**: Diarrhea, epigastric pain, nausea, thirst, vomiting

**GU**: Decreased urine output

**MS**: Muscle cramps or weakness

**RESP**: Dyspnea

**Other**: **Hyperkalemia**, **hyponatremia**, **hyperphosphatemia**, **hypocalcemia**, weight gain

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Monitor serum phosphorus level, as appropriate, in patient who receives phosphates and has a condition that may be associated with elevated phosphorus level, such as chronic renal disease, hypoparathyroidism, and rhabdomyolysis; phosphates may further increase serum phosphorus level.
- Monitor serum calcium level, as appropriate, in patient who receives phosphates and has a condition that may be associated with a low-calcium level, such as acute pancreatitis, chronic renal disease, hypoparathyroidism, osteomalacia, rhabdomyolysis, and rickets; phosphates may further decrease serum calcium level.
- Monitor serum potassium level, as appropriate, if patient who receives potassium phosphate has a condition linked to elevated potassium level, such as acute dehydration, adrenal insufficiency, extensive tissue breakdown (as in severe burns), myotonia congenita, pancreatitis, rhabdomyolysis, and severe renal insufficiency; she may have increased risk of hyperkalemia.
- Monitor serum sodium level in patient who receives sodium phosphates and has a condition that may be worsened by sodium excess, such as heart failure, hypernatremia, hypertension, peripheral or pulmonary edema, pre-eclampsia, renal impairment, and severe hepatic disease.
- Monitor urine pH, as ordered, to assess effectiveness of drug used to acidify urine.
- When administering sodium phosphates, monitor ECG tracing frequently during I.V. infusion to detect arrhythmias.

## **PATIENT TEACHING**

- Instruct patient to take phosphates after meals to avoid GI upset and decrease laxative effect.
- Emphasize importance of not swallowing capsules or tablets whole; instead, advise patient to soak tablets in water or fruit juice for 2 to 3 minutes to dissolve them.
- Suggest chilling diluted drug to improve flavor, but caution against freezing.
- Encourage increased intake of fluids (8 oz/hr, if not contraindicated) to prevent renal calculi.
- Urge patient to notify prescriber immediately about muscle weakness or cramps, unexplained weight gain, or shortness of breath.
- Instruct patient who needs an iron supplement to take it 1 to 2 hours after taking phosphates.

## pramipexole dihydrochloride

**Mirapex, Mirapex ER**

### Class and Category

*Pharmacologic class:* Nonergoline dopamine agonist

*Therapeutic class:* Antiparkinsonian

### Indications and Dosages

➤ *To treat Parkinson's disease*

#### **TABLETS**

**Adults.** *Initial:* 0.125 mg three times a day for 1 wk, increased weekly thereafter as follows: for wk 2, 0.25 mg three times a day; for wk 3, 0.5 mg three times a day; for wk 4, 0.75 mg three times a day; for wk 5, 1 mg three times a day; for wk 6, 1.25 mg three times a day; and for wk 7, 1.5 mg three times a day. *Maintenance:* 1.5 to 4.5 mg daily in divided doses three times a day. *Maximum:* 4.5 mg daily.

**DOSAGE ADJUSTMENT** For patients with renal impairment, dosage reduced as follows: for creatinine clearance greater than 50 ml/min, initial dosage of 0.125 mg three times a day with maximum dose limited to 1.5 mg three times a day; for creatinine clearance of 30 to 50 ml/min, initial dosage reduced to 0.125 mg twice a day and maximum dose limited to 0.75 mg three times a day; for creatinine clearance of 15 to less than 30 ml/min, initial dosage reduced to 0.125 mg once a day and maximum dose limited to 1.5 mg once a day. Drug shouldn't be given to patients with creatinine clearance of less than 15 ml/min.

## **E.R. TABLETS**

**Adults.** *Initial:* 0.375 mg once daily, increased every 5 to 7 days, first to 0.75 mg and then by 0.75-mg increments, as needed.

*Maximum:* 4.5 mg daily.

**DOSAGE ADJUSTMENT** For patients with moderate renal impairment (creatinine clearance between 30 and 50 ml/min), initial dosage taken every other day with dosage adjustment done after 1 wk in increments of 0.375 mg only, as needed, to maximum dosage of 2.25 mg daily.

➤ *To treat restless legs syndrome*

## **TABLETS**

**Adults.** *Initial:* 0.125 mg once daily, 2 to 3 hr before bedtime. Increased in 4 to 7 days to 0.25 mg once daily 2 to

3 hr before bedtime, as needed. Further increased in 4 to 7 days to 0.5 mg once daily 2 to 3 hr before bedtime, as needed.

**DOSAGE ADJUSTMENT** For patients with moderate to severe renal impairment (creatinine clearance 20 to 60 ml/min) dosage interval for titration, if needed, increased to 14 days.

## Mechanism of Action

May stimulate dopamine receptors in the brain, thereby easing symptoms of Parkinson's disease, which is thought to be caused by a dopamine deficiency.

## Contraindications

Hypersensitivity to pramipexole or its components

## Interactions

### DRUGS

*butyrophenones, metoclopramide, phenothiazines, thioxanthenes:* Decreased pramipexole effectiveness

## Adverse Reactions

**CNS:** Abnormal behavior, amnesia, anxiety, asthenia, compulsive behaviors such as pathological gambling or uncontrollable shopping or sexual activity, confusion, dream disturbances, drowsiness, dyskinesia, dystonia, fatigue, fever, hallucinations, headache, insomnia, malaise, paranoia, restlessness, syncope

**CV:** **Cardiac failure**, edema, orthostatic hypotension

**EENT:** Diplopia, dry mouth, rhinitis, vision changes

**ENDO:** Inappropriate antidiuretic hormone secretion (SIADH)

**GI:** Anorexia, constipation, dysphagia, eating disorders, nausea, vomiting

**GU:** Altered libido, hypersexuality, impotence, urinary frequency, urinary incontinence

**MS:** Arthralgia, myalgia, myasthenia, postural deformity, **rhabdomyolysis**

**RESP:** Pneumonia

**SKIN:** Diaphoresis, erythema, pruritis, rash, urticaria

**Other:** Weight gain or loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk. However, lactation inhibition is likely to occur because drug inhibits prolactin secretion.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use pramipexole cautiously in patients with hallucinations, hypotension, or retinal problems (such as macular degeneration). Drug may worsen these conditions.
- Also use cautiously in patients with renal impairment because pramipexole elimination may be decreased.

- Monitor patient for postural deformity (antecollis, bent spine syndrome, Pisa syndrome) that may occur several months after pramipexole therapy has been initiated or after increasing dose. If present, notify prescriber and expect dosage to be decreased or drug discontinued, which may improve condition.
- Take safety precautions per facility policy until drug's CNS effects are known.
- Avoid stopping pramipexole abruptly because doing so may cause a symptom complex resembling neuroleptic malignant syndrome and consisting of altered level of consciousness, autonomic instability, hyperpyrexia, and muscle rigidity.
- Be aware that patient may be switched overnight from immediate-release pramipexole tablets to the extended-release tablets at the same daily dose. However, monitor effectiveness to determine if dosage adjustment may be necessary.
- Assess patient for skin changes regularly because melanomas may occur at a higher rate in patients with Parkinson's disease. It isn't clear if this is a result of the disease or drugs used to treat it.
- Know that some patients have reported worsening of their Parkinson's disease symptoms when tablet residue was visible in their stool. If this occurs, notify prescriber, as pramipexole therapy may have to be reevaluated.

## **PATIENT TEACHING**

- Advise patient to take pramipexole with meals if nausea occurs.
- Caution patient about possible dizziness, drowsiness, or light-headedness, which may result from orthostatic hypotension. Advise her not to rise quickly from a lying or sitting position to minimize these effects.
- Instruct patient to notify prescriber immediately about vision problems or urinary frequency or incontinence.
- Inform patient that improvement in motor performance and activities of daily living may take 2 to 3 weeks.
- Urge patient to have regular skin examinations by a dermatologist or other qualified health professional.
- Advise patient and his family to notify prescriber about onset of compulsive and intense urges, such as eating binges, compulsive

shopping, hypersexuality, or pathological gambling. Dosage may have to be reduced or drug discontinued.

- Caution patient not to stop taking pramipexole abruptly.
- Tell patient to alert prescriber if posture changes that cannot be controlled occur, such as neck bending forward; bending forward at the waist; or tilting sideways when sitting, standing, or walking.
- Remind patient that drug should be stored at room temperature.
- Advise patient to contact prescriber if he observes residue in his stool, which may resemble a swollen original E.R. tablet or swollen pieces of the original tablet.
- Advise patient to report unexplained muscle pain, tenderness, or weakness to prescriber.

## pramlintide acetate

### Symlin

## Class and Category

*Pharmacologic class:* Human amylin analogue

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *To achieve euglycemia in patients with type 1 diabetes who use mealtime insulin therapy but have not achieved desired glucose control*

## SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 15 mcg just before major meals with 50% reduced dosage of preprandial rapid-acting or short-acting

insulin, including fixed-mix insulins. When nausea has abated at least 3 days, dosage increased in increments of 15 mcg. *Maintenance:* 30 to 60 mcg before major meals.

**DOSAGE ADJUSTMENT** Dosage decreased to 30 mcg if nausea occurs and persists at higher dosages.

- *To achieve euglycemia in patients with type 2 diabetes who use mealtime insulin, with or without a sulfonylurea and/or metformin, and have not achieved desire glucose control*

## SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 60 mcg immediately before major meals combined with dosage reduction of preprandial rapid-acting or short-acting insulin, including fixed-mix insulins by 50%. When nausea has been absent for at least 3 days, dosage increased to 120 mcg before major meals.

**DOSAGE ADJUSTMENT** Dosage decreased to 60 mcg before major meals if nausea occurs and persists with 120-mcg dosage.

Route	Onset	Peak	Duration
SubQ	Unknown	19-21 min	3 hr

## Mechanism of Action

Slows the rate at which food is released from stomach to small intestine, thus reducing initial postprandial rise in serum glucose level. Pramlintide also suppresses glucagon secretion and promotes satiety, thus furthering weight loss, which also lowers serum glucose level.

Pramlintide is a synthetic analogue of amylin, a naturally occurring neuroendocrine hormone secreted with insulin by pancreatic beta cells. In diabetes, secretion of insulin and amylin is reduced or absent.

# Contraindications

Gastroparesis, hypersensitivity to pramlintide or its components; hypoglycemia unawareness

# Incompatibilities

Don't mix in same syringe as insulin because pharmacokinetic parameters of pramlintide become altered.

# Interactions

## DRUGS

*drugs that alter GI motility (such as anticholinergics) or slow intestinal absorption of nutrients (such as alpha-glucosidase inhibitors):* Altered effects of these drugs  
*insulin:* Alters pharmacokinetic parameters of pramlintide if mixed in the same syringe. Pramlintide and insulin must not be mixed together and must be administered as separate injections.

*oral drugs:* Delayed absorption

# Adverse Reactions

**CNS:** Dizziness, fatigue, headache

**EENT:** Blurred vision, pharyngitis

**GI:** Abdominal pain, anorexia, nausea, **pancreatitis**, vomiting

**MS:** Arthralgia

**RESP:** Coughing

**SKIN:** Diaphoresis

**Other:** **Hypersensitivity reactions**; local injection-site reaction, such as redness, swelling, or pruritus

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Do not mix pramlintide in the same syringe as insulin because the pharmacokinetic parameters of pramlintide become altered.
- Because of the risks involved with pramlintide therapy, insulin-using patients with type 1 or 2 diabetes must have failed to achieve adequate glycemic control despite individualized insulin management and must be receiving ongoing care with guidance of insulin prescriber and a diabetes educator before pramlintide is prescribed.
- Expect that certain patients won't be prescribed pramlintide because its risks may outweigh its benefits. These include patients with poor compliance with current insulin regimen, poor compliance with monitoring blood glucose level, a glycosylated hemoglobin greater than 9%, recurrent severe hypoglycemia that required assistance during past 6 months, hypoglycemia unawareness, gastroparesis, concurrent therapy with drugs that stimulate GI motility, and pediatric patients.
- Before pramlintide therapy starts, make sure patient's premeal insulin dosage has been reduced by 50%.
- Give drug immediately before main meals.
- Monitor patient's premeal and postmeal blood glucose levels regularly to determine effectiveness of pramlintide and insulin therapy and to detect hypoglycemia.

- For 3 hours after each dose of pramlintide, monitor patient closely for hypoglycemia, which may be severe, especially in patients with type 1 diabetes. Effects may include hunger, headache, sweating, tremor, irritability, and trouble concentrating. They may occur with a rapid decrease in blood glucose level regardless of glucose values.
- Although pramlintide doesn't cause hypoglycemia, its use with insulin increases the risk of insulin-induced severe hypoglycemia, which can result in loss of consciousness, coma, or seizures. If hypoglycemia occurs, provide supportive care, including glucagon if prescribed, and notify prescriber. Expect insulin dosage accompanying pramlintide to be reduced.
- Keep in mind that early warning symptoms of hypoglycemia may be different or less severe if patient has had diabetes for a long time; has diabetic nerve disease; takes a beta blocker, clonidine, guanethidine, or reserpine; or is under intensified diabetes control.
- Closely monitor patients taking oral antidiabetics, ACE inhibitors, disopyramide, fibrates, fluoxetine, MAO inhibitors, pentoxifylline, propoxyphene, salicylates, or sulfonamide antibiotics because of an increased risk of hypoglycemia.
- Expect pramlintide to be stopped if patient develops recurrent hypoglycemia that requires medical assistance, develops persistent nausea, or becomes noncompliant with therapy or follow-up visits.

## **PATIENT TEACHING**

- Alert patient that insulin-induced hypoglycemia may occur within 3 hours of injecting pramlintide. Review signs and symptoms and appropriate treatment. Tell patient to notify prescriber if hypoglycemia occurs because insulin dosage will have to be reduced.
- Emphasize need to monitor blood glucose level often, especially before and after eating.
- Tell patient to inject drug subcutaneously immediately before major meals using an insulin syringe to draw up dose and using the same technique as with insulin administration, including rotating sites. Or, if patient has been prescribed the Symlin Pen injector, show her how to use it. Advise patient to inject drug into her abdomen or thigh and not to use her arm as an injection site because absorption may be too variable.
- Warn patient not to mix pramlintide and insulin together in the same syringe.

- Warn patient that nausea is common with pramlintide; urge her to notify prescriber because dosage may have to be decreased.
- Caution patient that if she misses a dose, she should skip the missed dose and continue with the next scheduled dose.
- Instruct patient to keep unopened pramlintide vials in the refrigerator; vials that have been opened may be kept in the refrigerator or at room temperature. Vials should be discarded 28 days after opening.
- Caution patient to avoid hazardous activities that require mental alertness until effects of pramlintide are known.
- Reassure patient that pramlintide won't alter her awareness of or her body's response to insulin-induced hypoglycemia.
- Alert patient that she'll need close follow-up care, at least weekly until a target dose of pramlintide has been reached, she's tolerating the drug well, and her blood glucose level is stable.
- Instruct women of childbearing age to notify prescriber about planned, suspected, or known pregnancy because drug therapy will have to be adjusted.
- Explain that local injection-site reactions, such as redness, swelling or itching, may occur but usually resolve in a few weeks.
- Instruct patient using the SymlinPen to never share it with anyone else, even if the needle has been changed, because of a risk for transmission of bloodborne pathogens.

**prasugrel**

**Effient**

## **Class and Category**

*Pharmacologic class:* P2Y<sub>12</sub> platelet inhibitor  
(thienopyridine)

*Therapeutic class:* Antiplatelet

# Indications and Dosages

- *To reduce rate of thrombotic cardiovascular events (including stent thrombosis) in patients with acute coronary syndrome who will be managed with percutaneous coronary intervention because of non-ST-elevation MI, ST-elevation MI, or unstable angina*

## TABLETS

**Adults.** *Initial:* 60 mg as a loading dose and then 10 mg once daily. *Maintenance:* 10 mg once daily.

**DOSAGE ADJUSTMENT** For patients weighing less than 60 kg (132 lb), daily maintenance dosage may be reduced to 5 mg once daily.

Route	Onset	Peak	Duration
P.O.	2 hr	30 min	7-10 days

## Mechanism of Action

After forming active metabolite, irreversibly binds to ADP receptors on platelets to inhibit platelet activation and aggregation for the lifetime of the platelet, which is 7 to 10 days. Without platelet activation and aggregation, thrombus cannot form.

## Contraindications

Active bleeding, history of transient ischemic attack or stroke, hypersensitivity to prasugrel or its components

## Interactions

### DRUGS

*fibrinolytic agents, NSAIDs (chronic use), warfarin:*  
Increased risk of bleeding  
*opioids:* Decreased or delayed prasugrel absorption

## Adverse Reactions

**CNS:** Dizziness, fatigue, fever, headache, **intracranial hemorrhage**

**CV:** **Atrial fibrillation, bradycardia,** hypercholesterolemia, hyperlipidemia, hypertension, **hypotension**, peripheral edema

**EENT:** Epistaxis, retinal hemorrhage

**GI:** Diarrhea, **GI or retroperitoneal hemorrhage**, hepatic dysfunction, nausea

**HEME:** Anemia, **leukopenia, bleeding, severe thrombocytopenia, thrombotic thrombocytopenia purpura**

**MS:** Back or limb pain

**RESP:** Cough, dyspnea, **hemoptysis**

**SKIN:** Subcutaneous hematoma, rash

**Other:** **Anaphylaxis, angioedema, hypersensitivity reactions, malignancies**, noncardiac chest pain

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm due to risk of bleeding.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber once condition has stabilized before breastfeeding.

## Nursing Considerations

- Be aware that patient should be receiving daily aspirin therapy (75 or 325 mg) throughout prasugrel therapy.
- Be aware that drug isn't recommended for patients age 75 or older (except in high-risk situations such as history of previous MI or presence of diabetes) or in patients who have active bleeding or a history of a transient ischemic attack or stroke. Monitor patients closely who have other risk factors for bleeding, which include a body weight less than 60 kg or a history of bleeding. Also monitor patients who are also taking drugs that increase risk of bleeding, such as chronic use of NSAIDs, fibrinolytic therapy, heparin, or warfarin.
- Know that prasugrel shouldn't be given to patients likely to undergo emergency coronary artery bypass graft (CABG) surgery because of increased bleeding risk. Drug should be discontinued at least 7 days before any surgery.

**WARNING** Monitor patient closely for bleeding because prasugrel can cause life-threatening hemorrhage. Report hypotension in patients who have recently undergone CABG surgery or other surgical procedures, coronary angiography, or percutaneous coronary intervention while taking drug. In this setting, expect therapy to continue because stopping prasugrel, especially in first few weeks after acute coronary syndrome, increases the risk of adverse cardiovascular effects.

- Be aware that because prasugrel inhibits platelet aggregation for the lifetime of the platelet, which is 7 to 10 days, withholding a dose is unlikely help in managing a bleeding event or the risk of bleeding associated with an invasive procedure. Expect to administer exogenous platelets but only 6 hours after prasugrel loading dose or 4 hours after maintenance dose was given.

- Monitor patient's CBC regularly, as ordered, watching for evidence of thrombotic thrombocytopenic purpura, such as abnormal blood counts, fever, neurologic abnormalities, or renal dysfunction. Notify prescriber immediately because condition can be fatal. Expect to implement emergency treatment, such as plasmapheresis.

## PATIENT TEACHING

- Emphasize importance of taking prasugrel exactly as prescribed, without lapses in therapy, for drug to be effective and adverse reactions to be reduced.
- Advise patient not to break the tablets. Also tell patient to keep drug in the container it comes in and to keep the container closed tightly with the gray cylinder (desiccant) inside.
- Instruct patient to take daily dose of aspirin as prescribed.
- Discourage use of NSAIDs, including OTC products, during prasugrel therapy because of risk of bleeding.
- Caution patient that bleeding may last longer than usual. Instruct him to report unusual bleeding or bruising.
- Instruct patient to inform healthcare providers that he takes prasugrel.
- Urge patient to take precautions against bleeding, such as using an electric shaver and a soft-bristled toothbrush.
- Advise patient to avoid activities that could cause traumatic injury and bleeding.

**WARNING** Advise patient to seek immediate medical care if swelling of his face or throat occurs or if any signs of an allergic reaction develops that is persistent or becomes worse.

# pravastatin sodium

## Pravachol

## Class and Category

*Pharmacologic class:* HMG-CoA reductase inhibitor (statin)

*Therapeutic class:* Antilipemic

## Indications and Dosages

- *To prevent cardiovascular and coronary events in patients at risk, to treat hyperlipidemia*

### **TABLETS**

**Adults.** *Initial:* 40 mg daily at bedtime, increased in 4 wk to 80 mg daily at bedtime, if needed.

***DOSAGE ADJUSTMENT*** For patients with significant hepatic or renal impairment, those taking immunosuppressants, and elderly patients, initial dosage reduced to 10 mg daily at bedtime. For elderly patients and those taking immunosuppressants, maintenance dosage usually limited to 20 mg daily. For patients taking clarithromycin, dosage limited to 40 mg once daily.

- *To treat pediatric heterozygous familial hypercholesterolemia*

### **TABLETS**

**Adolescents ages 14 to 18.** 40 mg daily at bedtime.

**Children ages 8 to 14.** 20 mg daily at bedtime.

## Mechanism of Action

Inhibits cholesterol synthesis in liver by blocking the enzyme needed to convert hydroxymethylglutaryl-CoA (HMG-CoA) to mevalonate, a cholesterol precursor. When

cholesterol synthesis is blocked, the liver also increases breakdown of LDL cholesterol.

## Contraindications

Active hepatic disease or unexplained, persistent elevated liver enzymes; breastfeeding; hypersensitivity to pravastatin or its components; pregnancy

## Interactions

### DRUGS

*niacin*: Increased risk of skeletal muscle effects  
*clarithromycin and other macrolide antibiotics, colchicine, cyclosporine, gemfibrozil, other fibrates*: Increased risk of rhabdomyolysis and acute renal failure

## Adverse Reactions

**CNS:** Anxiety, asthenia, chills, confusion, cognitive impairment, cranial nerve dysfunction, depression, dizziness, fatigue, headache, malaise, memory loss, nervousness, nightmare, peripheral nerve palsy, sleep disturbance

**CV:** Angina pectoris, chest pain, vasculitis

**EENT:** Blurred vision, diplopia, rhinitis

**ENDO:** Abnormal thyroid function, elevated glycosylated hemoglobin levels, gynecomastia, hyperglycemia

**GI:** Abdominal pain, cholestatic jaundice, cirrhosis, constipation, diarrhea, elevated liver enzymes, flatulence, **fulminant hepatic necrosis**, heartburn, hepatoma, **hepatic failure, hepatitis**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** Dysuria, nocturia, urinary frequency

**HEME:** Hemolytic anemia, positive ANA, ESR elevation, purpura

**MS:** Arthralgia, musculoskeletal cramps or pain, myalgia, myopathy, polymyalgia rheumatica, rhabdomyolysis, tendon disorder

**RESP:** Cough, dyspnea, interstitial lung disease, upper respiratory tract infection

**SKIN:** Dermatomyositis, erythema multiforme, photosensitivity, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis

**Other:** Anaphylaxis, angioedema, lupus-like syndrome

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in pregnant women.
- Drug should be discontinued immediately when pregnancy is known.

### LACTATION

- Drug is present in breast milk.
- Drug is contraindicated with breastfeeding,

### REPRODUCTION

- Women of childbearing age should use a reliable contraceptive throughout pravastatin therapy.

## Nursing Considerations

- Use pravastatin cautiously in patients with hepatic or renal impairment and in elderly patients.
- Monitor liver enzymes before pravastatin therapy starts and as indicated during therapy.
- Give drug 1 hour before or 4 hours after giving cholestyramine or colestipol.
- Report unexplained muscle aches or weakness and significant increases in creatine kinase level to prescriber because in rare instances drug causes rhabdomyolysis with acute renal failure caused by myoglobinuria. Expect to stop drug and provide supportive care.
- Monitor patient's BUN and serum creatinine levels periodically for abnormal elevations.
- Monitor blood lipoprotein level, as indicated, to evaluate response to therapy.

## **PATIENT TEACHING**

- Instruct patient to take drug at bedtime, without regard to meals.
- Caution patient not to perform hazardous activities such as driving until effects of drug is known.
- Advise patient to notify prescriber at once about muscle pain, tenderness, weakness, and other evidence of myopathy.
- Urge woman of childbearing age to use a reliable method of contraception during pravastatin therapy and to notify prescriber at once if she becomes pregnant or thinks she may be pregnant.
- Advise women not to breastfeed while on pravastatin therapy.
- Instruct patient not to stop taking pravastatin without consulting prescriber, even when cholesterol level returns to normal.

**prazosin hydrochloride**

**Minipress**

# Class and Category

*Pharmacologic class:* Alpha blocker

*Therapeutic class:* Antihypertensive

## Indications and Dosages

➤ *To manage hypertension*

### CAPSULES

**Adults.** *Initial:* 1 mg twice daily or three times a day.

*Maintenance:* 6 to 15 mg daily in divided doses twice daily or three times a day. *Maximum:* 40 mg daily.

***DOSAGE ADJUSTMENT*** For patient taking a diuretic or other antihypertensive agent, dosage reduced to 1 or 2 mg three times a day and retitration done. For patient taking a PDE05 inhibitor, therapy should be initiated at the lowest dose possible.

Route	Onset	Peak	Duration
P.O.	0.5-1.5 hr	2-4 hr*	7-10 hr

\* For a single dose; 3 to 4 wk for multiple doses.

## Mechanism of Action

Selectively and competitively inhibits  $\alpha_1$ -adrenergic receptors. This action promotes peripheral arterial and venous dilation and reduces peripheral vascular resistance, thereby lowering blood pressure.

## Contraindications

Hypersensitivity to prazosin, other quinazolines, or their components

## Interactions

### DRUGS

*antihypertensives, beta blockers, diuretics, phosphodiesterase-5 inhibitors:* Increased risk of hypotension and syncope

## Adverse Reactions

**CNS:** Asthenia, dizziness, drowsiness, fatigue, headache, insomnia, malaise, nervousness, syncope

**CV:** Angina, **bradycardia**, edema, orthostatic hypotension, palpitations, vasculitis

**EENT:** Dry mouth, eye pain

**ENDO:** Gynecomastia

**GI:** Nausea

**GU:** Priapism, urinary frequency or incontinence

**SKIN:** Urticaria

**Other:** **Hypersensitivity reactions**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use prazosin cautiously in patients with renal impairment because of increased sensitivity to prazosin's effects; in those with angina pectoris because drug may induce or aggravate angina; in those with narcolepsy because prazosin may worsen cataplexy; and in elderly patients because they're at increased risk for drug-induced hypotension.
- Monitor blood pressure regularly to evaluate effectiveness of therapy.

## PATIENT TEACHING

- Instruct patient who is starting prazosin to take drug at bedtime to minimize effects of first-dose hypotension.
- Emphasize need to take drug even if feeling well.
- Advise patient to avoid drinking alcohol, exercising in hot weather, or standing for long periods because these activities increase risk of orthostatic hypotension.
- Suggest rising slowly from lying or sitting position to minimize orthostatic hypotension.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to notify prescriber immediately about adverse reactions, especially dizziness and fainting.
- Instruct patient not to take any drugs, including OTC forms, without consulting prescriber, to avoid serious interactions.
- Instruct male patient that a prolonged erection may occur with prazosin therapy. If it lasts longer than 4 hours, stress importance of seeking immediate medical assistance.

**prednisolone**

**Delta-Cortef, Prelone**

**prednisolone acetate**

**Cotolone, Key-Pred 25, Predalone 50, Predcor-50**

**prednisolone sodium phosphate**

**Orapred ODT, Pediapred**

## **Class and Category**

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Immunosuppressant

## **Indications and Dosages**

- *To treat adrenal insufficiency and acute and chronic inflammatory and immunosuppressive disorders*

**SYRUP, TABLETS (PREDNISOLONE);  
DISINTEGRATING TABLETS, ORAL SOLUTION  
(PREDNISOLONE SODIUM PHOSPHATE); ORAL  
SUSPENSION (PREDNISOLONE ACETATE)**

**Adults.** 5 to 60 mg daily or in divided doses.

**Children.** *Initial:* 0.14 to 2 mg/kg/day. Alternatively, 4 to 60 mg/m<sup>2</sup>/day or 5 to 60 mg once a day or in divided doses 2 to 4 times a day. Then dosage adjusted, as needed.

*Maintenance:* Gradual decrease in small decrements to lowest dose that maintains an adequate clinical response.

### **I.M. INJECTION (PREDNISOLONE ACETATE)**

**Adults.** 4 to 60 mg daily in 2 divided doses and given every 12 hr.

### **INTRA-ARTICULAR, INTRALESIONAL, OR SOFT-TISSUE INJECTION (PREDNISOLONE TEBUTATE)**

**Adults.** 4 to 40 mg into joints and lesions, repeated as needed.

➤ *To treat acute exacerbations of multiple sclerosis*

### **SYRUP, TABLETS (PREDNISOLONE); DISINTEGRATING TABLETS, ORAL SOLUTION (PREDNISOLONE SODIUM PHOSPHATE); ORAL SUSPENSION (PREDNISOLONE ACETATE)**

**Adults.** 200 mg once daily for 1 wk, followed by 80 mg every other day for 1 mo.

➤ *To treat uncontrolled asthma in children taking inhaled corticosteroids and long-acting bronchodilators*

### **DISINTEGRATING TABLETS, ORAL SOLUTION (PREDNISOLONE SODIUM PHOSPHATE)**

**Children.** 1 to 2 mg/kg once a day or in divided doses continued for 3 to 10 days but may be used longer, if needed.

➤ *To treat pediatric nephrotic syndrome*

### **DISINTEGRATING TABLETS, ORAL SOLUTION (PREDNISOLONE SODIUM PHOSPHATE)**

**Children.***Initial:* 60 mg/m<sup>2</sup>/day divided into three doses for 4 wks, followed by 40 mg/m<sup>2</sup>/day once every other day for 4 wks.

Route	Onset	Peak	Duration
P.O.*	Unknown	1-2 hr	1.25-1.5 days
I.M.†	Slow	Unknown	Unknown
Intra- articular, intralesional, soft-tissue injection‡	1-2 days	Unknown	1-3 wk

\* Prednisolone.

† Prednisolone acetate.

‡ Prednisolone tebutate.

## Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

## Contraindications

Hypersensitivity to prednisolone or its components, idiopathic thrombocytopenic purpura (I.M. form), systemic fungal infection

## Interactions

## **DRUGS**

*aminoglutethimide*: Possibly loss of induced adrenal suppression

*amphotericin B, diuretics*: Possibly severe hypokalemia

*antacids, cholestyramine, colestipol*: Decreased prednisolone absorption

*anticholinesterase agents*: Possibly severe weakness in patients with myasthenia gravis.

*barbiturates, phenytoin, rifampin*: Decreased prednisolone effects

*cyclosporine*: Increased risk of seizures

*digoxin*: Possibly arrhythmias and digitalis toxicity from hypokalemia

*estrogens, oral contraceptives*: Decreased clearance, increased elimination half-life, and increased therapeutic and toxic effects of prednisolone

*insulin, oral antidiabetics*: Increased risk of hyperglycemia

*ketoconazole, macrolide antibiotics*: Possibly decreased prednisolone metabolism

*isoniazid, salicylates*: Decreased blood level of these drugs

*live or inactivated vaccines, toxoids*: Possibly diminished response to vaccines or toxoids

*NSAIDs*: Increased risk of GI ulceration and bleeding, possibly added therapeutic effect when NSAIDs are used to treat arthritis

*warfarin*: Possibly inhibition of warfarin effect

## **FOODS**

*sodium-containing foods*: Increased risk of edema and hypertension

## **ACTIVITIES**

*alcohol use*: Increased risk of GI ulceration and bleeding

# Adverse Reactions

**CNS:** Euphoria, headache, insomnia, nervousness, psychosis, restlessness, **seizures**, vertigo

**CV:** Edema, **heart failure**, hypertension

**EENT:** Cataracts, exophthalmos, glaucoma, increased ocular pressure

**ENDO:** **Adrenal insufficiency**, Cushing's syndrome, growth suppression in children, hyperglycemia

**GI:** Anorexia, **GI bleeding** and ulceration, increased appetite, indigestion, **intestinal perforation**, nausea, **pancreatitis**, vomiting

**GU:** Menstrual irregularities

**MS:** Avascular necrosis of joints, bone fractures, muscle atrophy or weakness, myalgia, osteoporosis, tendon rupture (local injection only)

**SKIN:** Acne; cutaneous or subcutaneous atrophy (with frequent repository injections); diaphoresis; ecchymosis; flushing; petechiae; striae; thin, fragile skin

**Other:** Delayed wound healing, **hypernatremia**, **hypokalemia**, injection-site scarring, negative nitrogen balance

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.
- Monitor infant for hypoadrenalism if mother has received large doses of drug during pregnancy.

## LACTATION

- Drug is present in breast milk and, in high doses, could interfere with endogenous corticosteroid production, suppress growth, or cause other adverse effects in the breastfed infant.
- The lowest dose possible is recommended to minimize exposure to breastfed infant.

## Nursing Considerations

**WARNING** Avoid using prednisolone in patients with a history of active tuberculosis because drug can reactivate the disease.

- Give once-daily doses in the morning to mirror body's normal cortisol secretion.
- Inspect injectable form for particulates and discoloration before administering.
- For I.M. injection, shake suspension well before withdrawing. Keep in mind that I.M. injections are contraindicated in patients with idiopathic thrombocytopenic purpura.
- For intra-articular injection, attach a 20G to 24G needle to empty syringe, using aseptic technique, so prescriber can remove a few drops of synovial fluid to confirm that needle is in the joint. The aspirating syringe is then exchanged with a prednisolone-filled syringe to inject drug into joint.
- Because prednisolone can produce many adverse reactions, assess patient regularly for evidence of such reactions, including heart failure and hypertension. Also monitor patient's intake, output, and daily weight.
- Monitor growth pattern in children; prednisolone may retard bone growth.
- Prolonged use may cause hypothalamic-pituitary-adrenal suppression.

**WARNING** Withdraw drug gradually, as ordered, if therapy lasts longer than 2 weeks. Stopping abruptly may cause acute adrenal insufficiency or, possibly, death.

- Be aware that patient may be at risk for emotional instability or psychic disturbance while taking prednisolone, especially if predisposed to them or taking high doses.

## PATIENT TEACHING

- Instruct patient to take oral prednisolone with food to decrease stomach upset and to take once-daily dose in the morning.
- Emphasize need to take drug exactly as prescribed; taking too much increases risk of serious adverse reactions.
- Instruct patient taking orally disintegrating tablets to remove tablet from blister pack only when ready to take drug and to place tablet on tongue. Warn her not to break, cut, or split tablets.
- Caution patient not to discontinue drug abruptly.
- Urge patient to avoid alcohol during therapy because of increased risk of GI ulcers and bleeding.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid people with contagious infections because drug has an immunosuppressant effect. Urge her to notify prescriber immediately about exposure to measles or chickenpox.
- Caution against receiving vaccinations or other immunizations and coming in contact with people who have recently received oral poliovirus vaccine.
- Teach patient about potential side effects of prednisolone therapy, including restlessness, mood swings, nervousness, and delayed wound healing.
- Instruct patient to notify prescriber immediately about joint pain, swelling, tarry stools, and visual disturbances. Also instruct her to report signs of infection or injury for up to 12 months after therapy.
- Advise patient to restrict joint use after intra-articular injection and to obtain activity guidelines from prescriber.
- Instruct diabetic patient to check her blood glucose level often because prednisolone may cause hyperglycemia.
- Advise patient to comply with follow-up visits to assess drug's effectiveness and detect adverse reactions.
- Urge patient to carry medical identification revealing prednisolone therapy.

# prednisone

## Prednisone Intensol, Rayos, Winpred (CAN)

### Class and Category

*Pharmacologic class:* Glucocorticoid

*Therapeutic class:* Immunosuppressant

### Indications and Dosages

- *To treat adrenal insufficiency and acute and chronic inflammatory and immunosuppressive disorders*

#### DELAYED-RELEASE TABLETS, ORAL SOLUTION, TABLETS

**Adults.** 5 to 60 mg daily as a single dose or in divided doses.

**Children.** 0.5 to 2 mg once daily or in divided doses.

*Maximum:* 80 mg daily.

- *To treat acute exacerbations of multiple sclerosis*

#### DELAYED-RELEASE TABLETS, ORAL SOLUTION, TABLETS

**Adults.** 200 mg daily for 1 wk, then 80 mg every other day for 1 mo.

Route	Onset	Peak	Duration
P.O.	Rapid	1-2 hr	1.25-1.5 days

# Mechanism of Action

Binds to intracellular glucocorticoid receptors and suppresses inflammatory and immune responses by:

- inhibiting neutrophil and monocyte accumulation at inflammation site and suppressing their phagocytic and bactericidal activity
- stabilizing lysosomal membranes
- suppressing antigen response of macrophages and helper T cells
- inhibiting synthesis of inflammatory response mediators, such as cytokines, interleukins, and prostaglandins.

# Contraindications

Hypersensitivity to prednisone or its components, systemic fungal infection

# Interactions

## DRUGS

*aminoglutehimide*: Possibly loss of corticosteroid-induced adrenal suppression

*amphotericin B (parenteral)*: Possibly development of cardiac enlargement and congestive heart failure

*anticholinesterase agents*: Possibly severe weakness in patients with myasthenia gravis

*cholestyramine*: Increased clearance of prednisone

*cyclosporine*: Increased risk of seizures

*CYP3A4 inducers (barbiturates, phenytoin, carbamazepine, rifampin)*: Increased metabolism of prednisone

*CYP3A4 inhibitors (ketoconazole, macrolide antibiotics)*: Decreased prednisone metabolism

*digoxin*: Possibly arrhythmias and digitalis toxicity from hypokalemia

*diuretics*: Possibly decreased natriuretic and diuretic effects of diuretics, severe hypokalemia (with potassium-depleting diuretics)

*estrogens, oral contraceptives*: Decreased clearance, increased elimination half-life, and increased therapeutic and toxic effects of prednisone

*insulin, oral antidiabetic agents*: Possibly less effective causing increased blood glucose levels

*isoniazid*: Decreased blood isoniazid level

*NSAIDs*: Increased risk of GI ulceration and bleeding, possibly added therapeutic effect when NSAIDs are used to treat arthritis

*toxoids, vaccines*: Possibly loss of antibody response, increased risk of neurologic complications

*warfarin*: Increased risk of reduced effectiveness of warfarin

## **FOODS**

*sodium-containing foods*: Increased risk of edema and hypertension

## **ACTIVITIES**

*alcohol use*: Increased risk of GI ulceration and bleeding

## **Adverse Reactions**

**CNS**: Euphoria, headache, insomnia, nervousness, psychosis, restlessness, **seizures**, vertigo

**CV**: Edema, **heart failure**, hypertension

**EENT**: Cataracts, exophthalmos, glaucoma, increased ocular pressure

**ENDO**: **Adrenal insufficiency**, Cushing's syndrome, growth suppression in children, hyperglycemia

**GI:** Anorexia, **GI bleeding** and ulceration, increased appetite, indigestion, **intestinal perforation**, nausea, **pancreatitis**, vomiting

**GU:** Menstrual irregularities

**MS:** Avascular necrosis of joints, bone fractures, muscle atrophy or weakness, myalgia, osteoporosis

**SKIN:** Acne; diaphoresis; ecchymosis; flushing; petechiae; striae; thin, fragile skin

**Other:** Delayed wound healing, **hyponatremia**, **hypokalemia**, negative nitrogen balance

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm although animal studies suggest a higher risk for cleft palate.
- Drug should be used with caution during pregnancy only if benefit to mother outweighs potential risk to fetus.
- Monitor infant for hypoadrenalism if mother has received large doses of drug during pregnancy.

### LACTATION

- Drug is present in breast milk and high doses could interfere with endogenous corticosteroid production, suppress growth, or cause other adverse effects in the breastfed infant.
- Lowest dose of drug used to minimize exposure to breastfed infant.

## Nursing Considerations

- Administer once-daily doses of prednisone in the morning to match body's normal cortisol secretion schedule.

- Because prednisone can produce many adverse reactions, assess regularly for signs and symptoms of such reactions as heart failure and hypertension. Also monitor fluid intake and output and daily weight.
- Monitor growth pattern in children. Prednisone may retard bone growth.
- Be aware that prolonged use of prednisone may cause hypothalamic-pituitary-adrenal suppression.

**WARNING** Withdraw prednisone gradually, as ordered, if therapy lasts longer than 2 weeks. Stopping abruptly may cause acute adrenal insufficiency and, possibly, death.

## PATIENT TEACHING

- Instruct patient to take prednisone with food to decrease GI distress and to take once-daily dose in the morning.
- Emphasize importance of taking drug exactly as prescribed; taking more than prescribed increases risk of serious adverse reactions.
- Tell patient prescribed delayed-release tablet form not to break, divide, or chew tablet because the delayed-release action is dependent on an intact coating.
- Caution patient not to stop drug abruptly.
- Urge patient to avoid alcohol during therapy because of increased risk of GI ulcers and bleeding.
- Urge patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to avoid people with contagious infections because drug has an immunosuppressant effect. Urge her to notify prescriber immediately about possible exposure to measles or chickenpox.
- Caution against receiving vaccinations or other immunizations and coming in contact with people who have recently received oral poliovirus vaccine.
- Instruct patient to notify prescriber immediately about joint pain, swelling, tarry stools, and visual disturbances. Also instruct her to report signs of infection or injury for up to 12 months after therapy.

- Instruct diabetic patient to check blood glucose level often because prednisone may cause hyperglycemia.
- Advise patient to comply with follow-up visits to assess drug effectiveness and detect adverse reactions.
- Urge patient to carry medical identification revealing prednisone therapy.

## pregabalin

**Lyrica, Lyrica CR**

### Class, Category, and Schedule

*Pharmacologic class:* Gamma-aminobutyric acid (GABA) analogue

*Therapeutic class:* Analgesic, anticonvulsant

*Controlled substance schedule:* V

### Indications and Dosages

- *To relieve neuropathic pain associated with diabetic peripheral neuropathy*

#### **CAPSULES, ORAL SOLUTION**

**Adults.** *Initial:* 50 mg three times a day, increased to 100 mg three times a day, within 1 wk as needed.

#### **E.R. TABLETS**

**Adults.** *Initial:* 165 mg once daily after evening meal, then increased to 330 mg once daily after evening meal within 1 wk, as needed and tolerated. *Maximum:* 330 mg once daily.

- *To relieve postherpetic neuralgia*

## **CAPSULES, ORAL SOLUTION**

**Adults.** *Initial:* 75 mg twice daily or 50 mg three times a day, increased to 150 mg twice daily or 100 mg three times a day within 1 wk as needed. Then increased to 300 mg twice daily or 200 mg three times a day in 2 to 4 wk as needed.

## **E.R. TABLETS**

**Adults.** *Initial* 165 mg once daily after evening meal, then increased to 330 mg once daily after evening meal within 1 wk, as needed and tolerated. Dosage further increased to 660 mg once daily after evening meal after 2 to 4 wk, if needed and tolerated. Maximum: 660 mg once daily.

- *As adjunct therapy to manage partial-onset seizures*

## **CAPSULES, ORAL SOLUTION**

*Adults and adolescents 17 years and older. Initial:* 150 mg daily in two or three divided doses, then increased as needed. *Maximum:* 600 mg daily in two or three divided doses.

*Children weighing 30 kg (66 lb) or more. Initial:* 2.5 mg/kg/day in two or three divided doses, then increased as needed. *Maximum:* 10 mg/kg/day in two or three divided doses, not to exceed 600 mg/day.

*Children age 4 and over weighing less than 30 kg (66 lb). Initial:* 3.5 mg/kg/day in two or three divided doses.

*Maximum:* 14 mg/kg/day in two or three divided doses.

**Infants and children age 1 month and over weighing less than 30 kg (66 lb).** *Initial:* 3.5 mg/kg/day in three divided doses. *Maximum:* 14 mg/kg/day in three divided doses.

- *To manage fibromyalgia*

## **CAPSULES, ORAL SOLUTION**

**Adults.** *Initial:* 75 mg twice daily, increased to 150 mg twice daily in 1 wk, as needed, and then to 225 mg twice daily in 1 wk as needed. *Maximum:* 450 mg daily.

- *To manage neuropathic pain associated with spinal cord injury*

## **CAPSULES, ORAL SOLUTION**

**Adults.** *Initial:* 75 mg twice daily, increased to 150 mg twice daily in 1 wk, as needed, and then to 300 mg twice daily after 2 to 3 wk, as needed.

***DOSAGE ADJUSTMENT*** For adult patient with renal impairment with a creatinine clearance of 30 to 60 ml/min, daily dosage reduced by 50%. Extended-release pregabalin should not be given to patients with creatinine clearance less than 30 ml/min. If clearance is 15 to 30 ml/min, daily dosage of immediate-release form reduced by 75% and frequency reduced to once or twice daily. If clearance is less than 15 ml/min, daily dosage of immediate-release form reduced to as low as 25 mg daily. If patient is having hemodialysis, daily dosage of immediate-release form is reduced and supplemental dose given immediately after every 4-hour hemodialysis session as follows: If reduced daily dosage is 25 mg daily, give supplemental dose of 25 or 50 mg. If reduced daily dosage is 25 to 50 mg daily, give supplemental dose of 50 or 75 mg. If reduced daily dosage is 50 to 75 mg daily, give supplemental dose of 75 or 100 mg. If reduced daily dosage is 75 mg, give supplemental dose of 100 or 150 mg.

<b>Route</b>	<b>Onset</b>	<b>Peak</b>	<b>Duration</b>
P.O.	Unknown	1.5 hr	Unknown

## Mechanism of Action

Binds to  $\alpha_2$ -delta site, an auxiliary subunit of voltage calcium channels, in CNS tissue where it may reduce calcium-dependent release of several neurotransmitters, possibly by modulating calcium channel function. With fewer neurotransmitters, pain sensation and seizure activity decline.

## Contraindications

Hypersensitivity to pregabalin or its components

## Interactions

### DRUGS

*lorazepam, oxycodone*: Additive effects on cognitive and gross motor function

### ACTIVITIES

*alcohol use*: Additive effects on cognitive and gross motor function

## Adverse Reactions

**CNS:** Abnormal gait, amnesia, anxiety, asthenia, ataxia, balance disorder, confusion, depression, difficulty concentrating, dizziness, euphoria, extrapyramidal syndrome, fatigue, fever, headache, hypertonia, hypesthesia, incoordination, **intracranial hypertension**, myoclonus, nervousness, neuropathy, paresthesia, psychotic depression, schizophrenic reaction, somnolence, stupor, **suicidal ideation**, tremor, twitching, vertigo

**CV:** Chest pain, **heart failure**, peripheral edema, **ventricular fibrillation**

**EENT:** Amblyopia, blurred vision, conjunctivitis, decreased visual acuity, diplopia, dry mouth, nystagmus, otitis media, sinusitis, tinnitus, visual field defect

**ENDO:** Gynecomastia, **hypoglycemia**

**GI:** Abdominal distention or pain, constipation, diarrhea, flatulence, gastroenteritis, **GI hemorrhage**, increased appetite, nausea, vomiting

**GU:** **Acute renal failure**, anorgasmia, decreased libido, glomerulitis, impotence, **nephritis**, urinary frequency, urinary incontinence, urine retention

**HEME:** **Leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, elevated creatine kinase level, leg or muscle cramps, myalgia, myasthenia

**RESP:** **Apnea**, dyspnea, pneumonia

**SKIN:** Ecchymosis, **exfoliative dermatitis**, pruritus, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**, **angioedema**, **hypersensitivity reactions**, increased risk of viral infection, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-888-233-2334 or <http://www.aedpregnancyregistry.org/>.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.

- Breastfeeding is not recommended because of the potential risk of tumorigenicity in the breastfed infant.

## **REPRODUCTION**

- Drug may cause a reduction in sperm concentration by 50% or more.

## **Nursing Considerations**

- Know that pregabalin therapy should be stopped gradually over at least 1 week to decrease risk of seizure activity and avoid unpleasant symptoms such as diarrhea, headache, insomnia, and nausea.
- Be aware that if patient has evidence of hypersensitivity (dyspnea, facial swelling, rash, red skin, urticaria, wheezing) drug should be stopped at once; notify prescriber, and give supportive care.
- Monitor patient closely for adverse reactions. Notify prescriber if significant adverse reactions persist. Be aware that children younger than 4 years has a higher chance of experiencing pneumonia, somnolence, or viral infection.
- Monitor patient closely for evidence of suicidal behavior or thinking, especially when therapy starts or dosage changes.

## **PATIENT TEACHING**

- Instruct patient prescribed extended-release tablets not to chew, crush, or split tablets but to swallow tablets whole. Tell patient to take tablets after evening meal.
- Tell patient converting from immediate-release formulation to extended release to take morning dose of immediate-release pregabalin and take first dose of extended-release form in the evening on the day of the switch.
- Warn against stopping pregabalin abruptly. Tell patient that when pregabalin is no longer needed, the dosage should be tapered gradually over a minimum of one week before it is discontinued.
- Urge patient to avoid hazardous activities until she knows how drug affects her.

- Instruct patient to notify prescriber if she has changes in vision or unexplained muscle pain, tenderness, or weakness, especially if these muscle symptoms are accompanied by fever or malaise.
- Alert patient that drug may cause edema and weight gain.
- Tell patient who also takes a thiazolidinedione antidiabetic that these effects may be intensified. If significant, tell patient to notify prescriber.
- Inform male patient who plans to father a child that drug could impair his fertility.
- Instruct diabetic patients to inspect their skin while taking pregabalin.
- Urge caregivers to watch patient closely for evidence of suicidal tendencies, especially when therapy starts or dosage changes and to report concerns at once to prescriber.
- Urge woman who becomes pregnant while taking pregabalin for seizures to enroll in the North American antiepileptic drug pregnancy registry by calling 1-888-233-2334. Explain that the registry is collecting information about the safety of antiepileptic drugs during pregnancy

## probenecid

### Benuryl (CAN), Probalan

## Class and Category

*Pharmacologic class:* Sulfonamide derivative

*Therapeutic class:* Uricosuric

## Indications and Dosages

- *To treat chronic gouty arthritis and hyperuricemia due to chronic gout*

### **TABLETS**

**Adults and adolescents.** *Initial:* 250 mg twice daily for 1 wk; then increased to 500 mg twice daily. Further increases may be made in 500 mg increments every 4 weeks if symptoms are not controlled or the 24 hour uric acid excretion is not above 700 mg. If no acute attacks of gout occur over next 6 mo and serum uric acid level is within normal limits, dosage decreased by 500 mg every 6 mo until lowest effective maintenance dose is reached. *Maximum:* 2 g daily.

➤ *As adjunct to antibiotic therapy with ampicillin, cloxacillin, methicillin, nafcillin, oxacillin, or penicillin*

## **TABLETS**

**Adults, adolescents age 14 and over, and children weighing more than 50 kg (110 lb).** 500 mg four times a day; if given with I.V. or I.M. antibiotic, administer at least 30 min before antibiotic.

**Children ages 2 to 14 weighing up to 50 kg.** 25 mg/kg as single dose, then 10 mg/kg four times a day; if given with I.V. or I.M. antibiotic, give at least 30 min before antibiotic.

Route	Onset	Peak	Duration
P.O.	Unknown	30 min*	8 hr <sup>†</sup>

\* For renal clearance of uric acid; 2 hr for effect on blood antibiotic level.

† For effect on blood antibiotic level; unknown for renal clearance of uric acid.

## **Mechanism of Action**

Increases urinary excretion of uric acid and lowers serum uric acid level, which may prevent or resolve urate deposits, tophus formation, and joint changes. Eventually, incidence of acute gout attacks decreases. Probenecid also

inhibits renal excretion of penicillins and some cephalosporins, thereby increasing their serum concentration and prolonging their duration of action.

## Contraindications

Acute gouty attacks (therapy not initiated), age less than 2 years, blood dyscrasias, hypersensitivity to probenecid or its components, renal calculi (urate)

## Interactions

### DRUGS

*acetaminophen, indomethacin, ketoprofen, lorazepam, meclofenamate, methotrexate, naproxen, penicillin or other beta-lactams, rifampin, sulindac, sulfonamides*: Possibly increased concentrations and adverse effects of these drugs

*salicylates*: Antagonized the uricosuric action of probenecid  
*thiopental*: Increased plasma concentration of thiopental, which significantly requires reduced dosage for induction of anesthesia

*theophylline*: Possibly falsely high readings for theophylline using the Schack and Waxler technique

## Adverse Reactions

**CNS:** Dizziness, headache

**EENT:** Sore gums

**GI:** Anorexia, nausea, vomiting

**GU:** Hematuria, renal calculi (urate), renal colic, urinary frequency

**MS:** Costovertebral pain; joint pain, redness, and swelling

**SKIN:** Facial flushing, pruritus, rash, urticaria

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm although it does cross the placental barrier.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that probenecid therapy shouldn't start until acute gout attack has subsided. If acute attack starts during therapy, continue therapy as prescribed.
- Use drug cautiously in patients with peptic ulcer disease.
- Expect to give sodium bicarbonate (3 to 7.5 g daily) or potassium citrate (7.5 g daily), as prescribed, to keep urine alkaline and prevent renal calculus formation.
- Monitor CBC, serum uric acid level, and liver and renal function test results during therapy.
- Closely monitor patients receiving intermittent therapy because they're more likely to develop allergic reactions.

## PATIENT TEACHING

- Advise patient to take probenecid with meals to minimize GI distress.
- Encourage patient to increase fluid intake (up to 3 L daily, if not contraindicated) to help prevent renal calculus formation.

- Instruct patient to notify prescriber immediately if she has signs of an acute gout attack (joint pain, swelling, and redness) or of renal calculi (flank pain and blood in urine).
- Caution patient against taking salicylates while taking probenecid. Instead, advise acetaminophen to treat mild pain or fever.

## procainamide hydrochloride

### Class and Category

*Pharmacologic class:* Sodium channel blocker of cardiomyocytes

*Therapeutic class:* Antiarrhythmic (Class 1a)

### Indications and Dosages

- *To treat life-threatening ventricular arrhythmias*

#### I.V. INFUSION OR INJECTION

**Adults.** *Initial loading dose:* 50 mg/min as an I.V. injection. Repeated every 5 min until arrhythmia is controlled or maximum total dose of 500 mg is reached. Dosing should not resume for at least 10 minutes or longer at this point. Once resumed, if needed, dosing continued at 50 mg/min with dosage repeated every 5 min until arrhythmia is controlled or maximum total dose of 1 g is reached. Alternatively, 20 mg/ml and given at a constant rate of 1 ml/min for 25 to 30 min. *Maintenance:* 1 to 4 mg/min by continuous infusion.

- *To treat ventricular extrasystoles and arrhythmias associated with anesthesia and surgery*

## I.M. INJECTION

**Adults.** 100 to 500 mg every 3 to 6 hr.

- *To treat less life-threatening arrhythmias in patients who are unable to take procainamide by mouth*

## I.M. INJECTION

**Adults.** *Initial:* 50 mg/kg daily and divided into equal doses given every 3 to 6 hr until oral dosage can be resumed.

***DOSAGE ADJUSTMENT*** For elderly patients or those with cardiac or hepatic insufficiency, dosage possibly reduced or dosing intervals increased. For patients with creatinine clearance less than 50 ml/min/1.73 m<sup>2</sup>, initial dosage reduced to 1 to 2 mg/min.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	60–90 min
P.O. (E.R.)	Unknown	60–90 min	Unknown
I.V.	Unknown	Immediate	Unknown
I.M.	10–30 min	15–60 min	Unknown

## Mechanism of Action

Prolongs recovery period after myocardial repolarization by inhibiting sodium influx through myocardial cell membranes. This action prolongs refractory period, causing myocardial automaticity, excitability, and conduction velocity to decline.

## Contraindications

Complete heart block, hypersensitivity to procainamide or its components, systemic lupus erythematosus, torsades de pointes

# Interactions

## DRUGS

*antiarrhythmics*: Additive cardiac effects

*anticholinergics*: Additive antivagal effects on A-V nodal conduction

*neuromuscular blockers*: Possibly increased or prolonged neuromuscular blockade

## Adverse Reactions

**CNS**: Chills, disorientation, dizziness, light-headedness

**CV**: **Heart block (second-degree), hypotension, pericarditis, prolonged QT interval**, tachycardia

**EENT**: Bitter taste

**GI**: Abdominal distress, anorexia, diarrhea, nausea, vomiting

**HEME**: **Agranulocytosis, neutropenia, thrombocytopenia**

**MS**: Arthralgia, myalgia

**RESP**: Pleural effusion

**SKIN**: Pruritus, rash

**Other**: Drug-induced fever

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- A decision may need to be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## **Nursing Considerations**

- Place patient in a supine position before giving procainamide I.M. or I.V. to minimize hypotensive effects. Monitor blood pressure often and ECG tracings continuously during administration and for 30 minutes afterward.
- Inspect parenteral solution for particles and discoloration before giving drug; discard if particles are present or solution is darker than light amber.
- If drug is to be given I.M. and patient's platelet count is below 50,000/mm<sup>3</sup>, notify prescriber at once because patient may develop bleeding, bruising, or hematomas from procainamide-induced bone marrow suppression and thrombocytopenia. Expect to give procainamide I.V.
- For I.V. injection, dilute procainamide with D<sub>5</sub>W according to manufacturer's instructions before administration.
- For I.V. infusion, dilute 200 to 1,000 mg of procainamide to a concentration of 2 or 4 mg/ml using 50 to 500 ml of D<sub>5</sub>W.
- Administer I.V. infusion with an infusion pump or other controlled-delivery device.
- Don't infuse or inject more than recommended amount per minute because heart block or cardiac arrest may occur.
- Anticipate that patient has reached maximum clinical response when ventricular tachycardia resolves, hypotension develops, or QRS complex is 50% wider than original width.

## **PATIENT TEACHING**

- Advise patient to notify prescriber immediately about bruising, chills, diarrhea, fever, or rash.

# prochlorperazine

**Compro**

prochlorperazine edisylate

prochlorperazine maleate

## Class and Category

*Pharmacologic class:* Piperazine phenothiazine

*Therapeutic class:* Antiemetic

## Indications and Dosages

➤ *To control nausea and vomiting related to surgery*

### **I.V. INFUSION OR INJECTION (PROCHLORPERAZINE EDISYLATE)**

**Adults.** 5 to 10 mg at a rate not to exceed 5 mg/ml 15 to 30 min before anesthesia or during or after surgery, as needed. Dosage repeated once, if necessary. *Maximum:* 10 mg/dose, 40 mg daily.

### **I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)**

**Adults.** 5 to 10 mg 1 to 2 hr before anesthesia or during or after surgery, as needed. Repeated once in 30 min, if needed. *Maximum:* 10 mg/dose, 40 mg daily.

- *To control severe nausea and vomiting*

## **TABLETS (PROCHLORPERAZINE MALEATE)**

**Adults and adolescents.** 5 to 10 mg three times a day or four times a day. *Maximum:* 40 mg daily.

**Children age 2 and over weighing 18 kg (40 lb) to 38.5 kg (85 lb).** 2.5 mg three times a day or 5 mg two times a day. *Maximum:* 15 mg daily.

**Children age 2 and over weighing 13.5 kg (30 lb) to 17 kg (39 lb).** 2.5 mg two or three times daily. *Maximum:* 10 mg daily.

**Children age 2 and over weighing 9 kg (20 lb) to 13 kg (29 lb).** 2.5 mg once or twice daily. *Maximum:* 7.5 mg daily.

## **I.V. INFUSION OR INJECTION (PROCHLORPERAZINE EDISYLATE)**

**Adults.** 2.5 to 10 mg at a rate not to exceed 5 mg/min. *Maximum:* 10 mg/dose; 40 mg daily.

## **I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)**

**Adults and adolescents.** 5 to 10 mg every 3 to 4 hr, as needed. *Maximum:* 40 mg daily.

**Children ages 2 to 12.** 0.132 mg/kg (0.06 mg/lb) then switched to oral form as soon as possible, usually after one dose.

## **SUPPOSITORIES (PROCHLORPERAZINE)**

**Adults.** 25 mg twice daily.

- *To manage psychotic disorders, such as schizophrenia*

## TABLETS (PROCHLORPERAZINE MALEATE)

**Adults and adolescents.** 5 to 10 mg three times a day or four times a day, increased gradually every 2 to 3 days, as needed and tolerated. *Maximum:* 150 mg daily.

**Children age 2 to 12 years.** *Initial:* 2.5 mg two or three times daily (maximum 10 mg first day), then increased, as needed. *Maximum:* For children 6 to 12, total daily dose of 25 mg beginning day 2 and onward, for children age 2 to 6, total daily dose of 20 mg beginning day two and onward.

## I.M. INJECTION (PROCHLORPERAZINE EDISYLATE)

**Adults and adolescents.**

*Initial:* 10 to 20 mg, repeated every 2 to 4 hr (or in resistant cases every hr), as needed, to bring symptoms under control (usually 3 to 4 doses). Then switched to oral dosing as soon as possible. *Maintenance:* If unable to switch to oral form, continue with 10 to 20 mg every 4 to 6 hr.

**Children ages 2 to 12.** 0.132 kg (0.06 mg/lb) then switched to oral form as soon as possible, usually after one dose.

***DOSAGE ADJUSTMENT*** Initial dose usually reduced and subsequent dosage increased more gradually for elderly, emaciated, and debilitated patients.

Route	Onset	Peak	Duration
P.O., I.V., I.M., P.R.	Up to several wk*	Up to 6 mo	Unknown

\* For antipsychotic effects; unknown for other indications.

## Mechanism of Action

Alleviates psychotic symptoms by blocking dopamine receptors, depressing release of selected hormones, and producing alpha-adrenergic blocking effect in the brain.

Prochlorperazine also alleviates nausea and vomiting by centrally blocking dopamine receptors in the medullary chemoreceptor trigger zone and by peripherally blocking the vagus nerve in the GI tract.

Anticholinergic effects and alpha-adrenergic blockade reduce anxiety by decreasing arousal and filtering internal stimuli to the brain stem reticular activating system.

## Incompatibilities

Don't mix prochlorperazine in same syringe with other drugs. Precipitate may form when prochlorperazine edisylate is mixed in same syringe with morphine sulfate.

## Contraindications

Age less than 2 years; coma, hypersensitivity to prochlorperazine, other phenothiazines or their components; pediatric surgery; severe CNS depression; use of large quantities of CNS depressants; weight less than 9 kg (20 lb)

## Interactions

### DRUGS

*anticonvulsants:* Possibly lowered seizure threshold by prochlorperazine

*antihypertensives such as guanethidine and related compounds:* Possibly action of these drugs may be counteracted by prochlorperazine

*CNS depressants:* Possibly intensify or prolong action of these drugs

*oral anticoagulants:* Possibly diminished effects of oral anticoagulants

*phenytoin:* Possible interference with phenytoin metabolism leading to phenytoin toxicity

*propranolol:* Increased plasma levels of both drugs

*thiazide diuretics:* Possibly accentuate orthostatic hypotension

## ACTIVITIES

*alcohol use:* Additive CNS depression

## Adverse Reactions

**CNS:** Akathisia, altered temperature regulation, dizziness, drowsiness, extrapyramidal reactions (such as dystonia, pseudoparkinsonism, tardive dyskinesia)

**CV:** **Hypotension**, orthostatic hypotension, tachycardia

**EENT:** Blurred vision, dry mouth, nasal congestion, ocular changes, pigmentary retinopathy

**ENDO:** Galactorrhea, gynecomastia

**GI:** Constipation, epigastric pain, nausea, vomiting

**GU:** Dysuria, ejaculation disorders, menstrual irregularities, urine retention

**SKIN:** Decreased sweating, photosensitivity, pruritus, rash

**Other:** Weight gain

## Childbearing Considerations

- Drug may cause fetal harm.
- Neonates exposed to drug during the third trimester of pregnancy are at risk for extrapyramidal and withdrawal symptoms after birth.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Prochlorperazine shouldn't be used to treat dementia-related psychosis in the elderly because of increased mortality risk.
- Avoid contact between skin and solution forms of prochlorperazine because contact dermatitis could result.
- Inject I.M. form slowly, deep into upper outer quadrant of buttocks. Keep patient supine for 30 minutes after injection to minimize hypotensive effects.
- Rotate I.M. injection sites to prevent irritation and sterile abscesses.
- Be aware that I.V. form may be given undiluted as injection or diluted in isotonic solution as infusion (mesylate form requires dilution in at least 1 L). Both forms should be given at no more than 5 mg/min.
- Protect prochlorperazine from light.
- Parenteral solution may develop slight yellowing that won't affect potency. Don't use if discoloration is pronounced or precipitate is present.
- Expect antipsychotic effects to occur in 2 to 3 weeks, although range is days to months.

**WARNING** Monitor closely for numerous adverse reactions that may be serious.

- Adverse effects may occur up to 12 weeks after discontinuation of E.R. capsules.

## PATIENT TEACHING

- Instruct patient to take prochlorperazine with food or a full glass of milk or water to minimize GI distress.
- Advise patient to swallow E.R. capsules whole, not to crush or chew them.
- Instruct patient using suppository to refrigerate it for 30 minutes or hold it under running cold water before removing the wrapper if it softens during storage.
- Teach patient correct administration technique for suppository.
- Caution patient on long-term therapy not to stop prochlorperazine abruptly; doing so may lead to such adverse reactions as nausea, vomiting, and trembling.
- Urge patient to avoid alcohol and OTC drugs that may contain CNS depressants.
- Advise patient to rise slowly from lying and sitting positions to minimize effects of orthostatic hypotension.
- Urge patient to avoid hazardous activities because of the risk of drowsiness and impaired judgment and coordination.
- Instruct patient to avoid excessive sun exposure and to wear sunscreen outdoors.
- Urge patient to notify prescriber about involuntary movements and restlessness.
- Explain that adverse effects may occur up to 12 weeks after stopping E.R. capsules.

**progestins levonorgestrel**

**medroxy progesterone  
acetate**

**Alti-MPA (CAN), Provera**

**megestrol acetate**

**Megace, Megace OS (CAN)**

**norethindrone acetate**

**Aygestin, Norlutate (CAN)**

**progesterone**

**Crinone, PMS-Progesterone (CAN),  
Prometrium**

## **Class and Category**

*Pharmacologic class:* Progesterone hormone

*Therapeutic class:* Ovarian hormone replacement

## **Indications and Dosages**

➤ *To treat metastatic renal cancer*

### **I.M. INJECTION (MEDROXYPROGESTERONE)**

**Adults and adolescents.** *Initial:* 400 mg to 1 g every wk until improvement and stabilization. *Maintenance:* 400 mg or more every mo.

➤ *To treat metastatic breast cancer*

### **TABLETS (MEGESTROL)**

**Adults and adolescents.** 40 mg four times daily.

➤ *To treat metastatic endometrial cancer*

## **TABLETS (MEGESTROL)**

**Adult and adolescent women.** 40 to 320 mg daily in divided doses.

## **I.M. INJECTION (MEDROXYPROGESTERONE)**

**Adults and adolescents.** *Initial:* 400 mg to 1 g every wk until improvement and stabilization. *Maintenance:* 400 mg or more every mo.

- *To treat anorexia, cachexia, or significant weight loss in patients who have AIDS*

## **SUSPENSION (MEGESTROL)**

**Adults and adolescents.** 800 mg daily for the first mo, and then 400 or 800 mg daily for the next 3 mo.

- *To treat endometriosis*

## **TABLETS (NORETHINDRONE ACETATE)**

**Adult and adolescent women.** *Initial:* 5 mg daily for 2 wk, increased by 2.5 mg daily at 2-wk intervals to total dose of 15 mg daily. *Maintenance:* 15 mg daily for 6 to 9 mo unless temporarily discontinued because of breakthrough menstrual bleeding.

- *To treat secondary amenorrhea*

## **TABLETS (MEDROXYPROGESTERONE)**

**Adult and adolescent women.** 5 to 10 mg daily for 5 to 10 days, starting anytime during menstrual cycle.

## **TABLETS (NORETHINDRONE ACETATE)**

**Adult and adolescent women.** 2.5 to 10 mg daily for 5 to 10 days during last half of menstrual cycle.

## **CAPSULES, TABLETS (PROGESTERONE)**

**Adult and adolescent women.** 400 mg daily at bedtime for 10 days.

## **I.M. INJECTION (PROGESTERONE)**

**Adult and adolescent women.** 5 to 10 mg daily for 6 to 10 days.

## **VAGINAL GEL (PROGESTERONE)**

**Adult and adolescent women.** 45 mg (1 applicatorful of 4% vaginal gel) every other day for up to 6 doses. Dosage increased, as needed, to 90 mg (1 applicatorful of 8% vaginal gel) every other day for up to 6 doses.

➤ *To treat dysfunctional uterine bleeding*

## **TABLETS (MEDROXYPROGESTERONE)**

**Adult and adolescent women.** 5 to 10 mg daily for 5 to 10 days, starting on day 16 or 21 of menstrual cycle.

## **TABLETS (NORETHINDRONE ACETATE)**

**Adult and adolescent women.** 2.5 to 10 mg daily for 5 to 10 days during last half of menstrual cycle.

## **I.M. INJECTION (PROGESTERONE)**

**Adult and adolescent women.** 5 to 10 mg daily for 6 consecutive days.

➤ *To reduce endometrial hyperplasia in nonhysterectomized postmenopausal women receiving daily oral conjugated estrogen therapy,*

## **TABLETS (MEDOXYPROGESTERONE)**

**Postmenopausal women with intact uterus.** 5 to 10 mg for 12 to 14 consecutive days each month, either beginning on the 1st day of the cycle or the 16th day of the cycle.

## **CAPSULES, TABLETS (PROGESTERONE)**

**Postmenopausal women with intact uterus.** 200 mg once day at bedtime for 12 consecutive days per 28 day cycle.

➤ *To prevent pregnancy (postcoital)*

## **TABLETS (LEVONORGESTREL)**

**Adult and adolescent women.** 0.75 mg as soon as possible within 72 hr of intercourse. Second dose given 12 hr later.

## **Mechanism of Action**

Progestins may diminish response to endogenous hormones in tumor cells by decreasing the number of steroid hormone receptors, causing a direct antiproliferative or cytotoxic effect on cell cycle growth and increased terminal cell differentiation. At higher doses, some progestins decrease adrenal production of androstenedione and estradiol, which may decrease estrogen- or testosterone-sensitive tumors. Megestrol stimulates appetite and metabolic effects, which promotes weight gain. Progestins also bind to cytosolic receptors that are loosely bound in cell nucleus, increasing protein synthesis and improving cachexia.

Progestins affect other hormones, especially estrogen, by reducing availability or stability of hormone receptor complex, shutting off estrogen-responsive genes, or causing negative feedback mechanism that decreases number of functioning estrogen receptors. These actions allow

menstrual cycle to function normally, alleviating amenorrhea and dysfunctional uterine bleeding and inducing menses. Progestins also act to transform proliferative uterine endometrium into a more differentiated, secretory one, which is the basis for using medroxyprogesterone to treat some types of amenorrhea. In a normal ovulatory cycle not resulting in pregnancy, decline in progesterone secretion caused by degeneration of corpus luteum in late luteal phase results in endometrial sloughing. A similar sloughing occurs after 5 to 10 days of medroxyprogesterone, provided that adequate estrogen-stimulated proliferation has occurred during follicular phase.

The progestin, levonorgestrel, also inhibits secretion of gonadotropins from pituitary gland, which creates an atrophic endometrium, resulting in contraceptive effect.

## **Contraindications**

Active thromboembolic disorder; thrombophlebitis; significant hepatic disease; hypersensitivity to sesame oil/seeds (progesterone), progestins, or their components; known or suspected breast or genital cancer; missed abortion (progesterone); pregnancy; undiagnosed vaginal bleeding

## **Interactions**

### **DRUGS**

*aminoglutethimide*: Possibly decreased blood level of medroxyprogesterone

*atazanavir, clarithromycin, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir,*

*telithromycin, voriconazole*: Possibly increased progestin level leading to potential for increased adverse reactions  
*barbiturates including primidone, bosentan, carbamazepine, felbamate, griseofulvin, oxcarbazepine, phenytoin, rifampin, St. John's wort, topiramate*: Possibly decreased effectiveness of progestin  
*CYP3A4 inhibitors such as ketoconazole*: Possibly increased bioavailability of progesterone  
*thyroid hormone*: Increased thyroid hormonal levels; decreased thyroid hormone effectiveness  
*warfarin*: Possibly increased INR

## Adverse Reactions

**CNS:** Altered or reduced coordination or speech, depression, dizziness, drowsiness, fatigue, headache, irritability, migraine, mood changes, nervousness, postmenopausal dementia, syncope, unusual tiredness or weakness

**CV:** Fluid retention; **hypotension**; numbness or pain in arm, chest, or leg; **thromboembolism**

**ENDO:** **Adrenal insufficiency or suppression**, breast pain or tenderness, Cushing's syndrome, decreased T<sub>3</sub> resin uptake, delayed return of fertility in women, elevated thyroid-binding globulin, galactorrhea, hyperglycemia

**EENT:** Gingival bleeding, swelling, or tenderness; vision changes or loss

**GI:** Abdominal cramps or pain, cholestatic jaundice, diarrhea, nausea, vomiting

**GU:** Amenorrhea, breakthrough bleeding or metromenorrhagia, changes in cervical erosion and secretions, decreased libido, hypermenorrhea, ovarian enlargement or cysts

**HEME:** **Clotting and bleeding abnormalities**

**MS:** Back pain, decreased bone density, osteoporosis, osteoporotic fractures

**RESP:** **Acute eosinophilic pneumonia** (progesterone in sesame oil), dyspnea

**SKIN:** Acne, alopecia, dermal edema, hirsutism, melasma, pruritus, rash, urticaria

**Other:** **Anaphylaxis**; **angioedema**; hot flashes; injection-site irritation, pain, or redness; weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm.
- Drug is contraindicated in pregnancy. If pregnancy occurs, drug should be discontinued immediately.

### LACTATION

- Drug is present in breast milk in small amounts.
- A decision may need to be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

## Nursing Considerations

- Be aware that progestin/estrogen therapy shouldn't be used to prevent cardiovascular disease or dementia.
- Use progestins cautiously in patients with risk factors for arterial vascular disease, such as diabetes mellitus, hypercholesterolemia, hypertension, obesity, systemic lupus erythematosus, tobacco use, or a family or personal history of venous thromboembolism. Drug worsen these conditions.
- Use progestins cautiously in patients who have CNS disorders, such as depression or seizures, because progestins may worsen these conditions.

- Shake container vigorously for at least 1 minute before giving medroxyprogesterone acetate injection suspension or megestrol acetate oral suspension.
- Inject parenteral medroxyprogesterone slowly, over 5 to 7 seconds, into deltoid muscle. Don't inject into gluteal muscle to lessen absorption problems that may occur when patient sits on injection site. Pat site lightly after injection; don't rub it.

**WARNING** Notify prescriber immediately if patient develops signs of thrombotic events. Expect to discontinue progestin if such signs occur and provide emergency care, as ordered.

- Monitor patient for adrenal suppression, especially with megestrol therapy. If suspected, notify prescriber.
- Expect to stop progestin therapy in any woman who develops evidence of cancer; cardiovascular disease such as CVA, MI, pulmonary embolism, or venous thrombosis; or dementia.
- Be aware that acute eosinophilic pneumonia may occur in patients receiving progesterone in sesame oil. Monitor patient for dyspnea with hypoxic respiratory insufficiency and fever that may occur 2 to 4 weeks after patient starts progesterone in sesame oil therapy. If this reaction is suspected, notify prescriber and expect drug to be discontinued immediately.

## **PATIENT TEACHING**

- Explain risks of progestin therapy, including breast, endometrial, or ovarian cancer; cardiovascular disease; dementia; and gallbladder disease, especially in postmenopausal women.
- Instruct woman to notify prescriber if uterine bleeding continues longer than 3 months or if menstruation is delayed by 45 days.
- Warn patient taking progestin for noncontraceptive purposes to use a contraceptive method to prevent pregnancy because drug may harm fetus.
- Advise female patient to contact prescriber immediately if she suspects pregnancy or misses a menstrual period.
- Advise patient that some products may contain peanut oil or sesame oil. If she is allergic to these, tell her to contact pharmacist to find out if

prescribed progestin product contains peanut or sesame oil. Also tell patient to report difficulty breathing and fever to prescriber.

- Caution female patient who vomits within 1 hour of taking progestin for emergency contraception to contact prescriber about whether to repeat dose.
- Teach woman how to use vaginal gel, if prescribed. Tell her to avoid using other vaginal products for 6 hours before and after to ensure gel's complete absorption.
- Direct patient to alert all prescribers about progestin therapy because certain blood tests may be affected.
- Emphasize importance of good dental hygiene and regular dental checkups because elevated progestin level increases growth of normal oral flora, which may lead to gum tenderness, bleeding, or swelling.
- Caution postmenopausal women about increased risk of dementia associated with progestin therapy.

## promethazine hydrochloride

### Promethegan

## Class and Category

*Pharmacologic class:* Phenothiazine

*Therapeutic class:* Antiemetic, antihistamine, antivertigo, sedative-hypnotic

## Indications and Dosages

➤ *To prevent or treat motion sickness*

**SUPPOSITORIES, SYRUP, TABLETS**

**Adults.** 25 mg 30 to 60 min before travel and repeated 8 to 12 hr later, if needed. Then, 25 mg twice daily, as needed.

**Children age 2 and over.** 0.5 mg/kg or 12.5 to 25 mg every 12 hr, as needed.

➤ *To prevent or treat nausea and vomiting in certain types of anesthesia and surgery*

## **SYRUP, TABLETS**

**Adults.** *Initial:* 12.5 to 25 mg; every 4 to 6 hr, as needed. *Maximum:* 150 mg daily.

**Children age 2 and over.** 1.1 mg/kg/dose (maximum 25 mg/dose) every 4 to 6 hr as needed.

## **I.V. OR I.M. INJECTION**

**Adults.** 12.5 to 25 mg every 4 hr, as needed. *Maximum:* 150 mg daily. I.V. injection diluted and given slowly over 10 to 15 min.

## **I.M. INJECTION**

**Children age 2 and over.** 6.25 to 12.5 mg/dose every 4 to 6 hr, as needed.

## **SUPPOSITORIES**

**Adults.** 12.5 to 25 mg every 4 to 6 hr, as needed. *Maximum:* 150 mg daily.

**Children age 2 and over.** 1.1 mg/kg/dose (maximum 25 mg/dose) every 4 to 6 hr, as needed.

➤ *To treat signs and symptoms of allergic response*

## **SUPPOSITORIES, SYRUP, TABLETS**

**Adults and adolescents.** 12.5 mg four times a day before meals and at bedtime, as needed. Or, 25 mg at bedtime, as

needed. *Maximum:* 150 mg daily.

**Children age 2 and over.** 6.25 to 12.5 mg three times a day, as needed. Or, 25 mg at bedtime, as needed.

## **I.M. OR I.V. INJECTION**

**Adults.** 25 mg with I.V. injection diluted and given slowly over 10 to 15 min, repeated within 2 hr, as needed.

- *As an adjunct to analgesics for preoperative or postoperative sedation*

## **I.M. OR I.V. INJECTION, SUPPOSITORIES, SYRUP, TABLETS**

**Adults.** 25 to 50 mg as a single dose. I.V. injection diluted and given slowly over 10 to 15 min.

## **SUPPOSITORIES, SYRUP, TABLETS**

**Children age 2 and over.** 1.1 mg/kg as a single dose.  
*Maximum:* 25 mg/dose.

## **I.M. INJECTION**

**Children age 2 and over.** 0.25 to 1.1 mg/kg as a single dose. *Maximum:* 25 mg/dose.

- *To relieve apprehension and promote nighttime sleep*

## **I.M. INJECTION, SYRUP, TABLETS, SUPPOSITORIES**

**Adults.** 25 to 50 mg at bedtime.

***DOSAGE ADJUSTMENT*** Dosage usually decreased for elderly patients.

- *To provide obstetric sedation*

## I.V. OR I.M. INJECTION

**Adults and adolescents.** 25 to 50 mg for early stages of labor; 25 to 75 mg after labor is established, repeated once or twice every 4 hr, as needed. I.V. injection diluted and given slowly over 10 to 15 min.

Route	Onset	Peak	Duration
P.O.	15-60 min	Unknown	4-6 hr
I.V.	3-5 min	Unknown	4-6 hr
I.M., P.R.	20 min	Unknown	4-6 hr

## Mechanism of Action

Competes with histamine for H<sub>1</sub>-receptor sites, thereby antagonizing many histamine effects and reducing allergy signs and symptoms. Promethazine also prevents motion sickness, nausea, and vertigo by acting centrally on medullary chemoreceptive trigger zone and by decreasing vestibular stimulation and labyrinthine function in the inner ear. It also promotes sedation and relieves anxiety by blocking receptor sites in CNS, directly reducing stimuli to the brain.

## Contraindications

Children under the age of 2; comatose state; hypersensitivity to promethazine, other pheothiazines, or their components; intra-arterial or subcutaneous injection (parenteral)

## Interactions

### DRUGS

*anticholinergics*: Possibly intensified anticholinergic adverse effects

*CNS depressants*: Additive CNS depression

*epinephrine*: Reversed vasopressor effect of epinephrine; increased risk of hypotension

*MAO inhibitors*: Increased risk of extrapyramidal effects

## ACTIVITIES

*alcohol use*: Additive CNS depression

## Adverse Reactions

**CNS**: Akathisia, CNS stimulation, confusion, dizziness, drowsiness, dystonia, euphoria, excitation, fatigue, hallucinations, hysteria, incoordination, insomnia, irritability, nervousness, **neuroleptic malignant syndrome**, paradoxical stimulation, pseudoparkinsonism, restlessness, sedation, **seizures**, syncope, tardive dyskinesia, tremor

**CV**: **Bradycardia**, hypertension, **hypotension**, tachycardia

**EENT**: Blurred vision; diplopia; dry mouth, nose, and throat; nasal congestion; tinnitus; vision changes

**ENDO**: Hyperglycemia

**GI**: Anorexia, cholestatic jaundice, ileus, nausea, rectal burning or stinging (suppository form), vomiting

**GU**: Dysuria

**HEME**: **Agranulocytosis**, **leukopenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**RESP**: **Apnea**, **respiratory depression**, tenacious bronchial secretions

**SKIN**: Dermatitis, diaphoresis, jaundice, photosensitivity, rash, urticaria

**Other**: **Angioedema**, paradoxical reactions

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm. However, drug should not be used within two weeks of delivery due to potential inhibition of platelet aggregation in the newborn.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- A decision may need to be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the breastfed infant.

# Nursing Considerations

- Use promethazine cautiously in children and elderly patients because they may be more sensitive to its effects, patients with cardiovascular disease or hepatic dysfunction because of potential adverse effects, patients with asthma because of anticholinergic effects, and patients with seizure disorders or those who take drugs that may affect seizure threshold because drug may lower seizure threshold.
- Inject I.M. form deep into large muscle mass, and rotate sites.

**WARNING** Avoid inadvertent intra-arterial injection of promethazine because it can cause arteriospasm. Also avoid injecting drug under skin; severe tissue damage and gangrene may develop from impaired circulation.

- Give I.V. injection at no more than 25 mg/min; rapid I.V. administration may produce a transient drop in blood pressure.

**WARNING** Monitor respiratory function because drug may suppress cough reflex and cause thickening of

bronchial secretions, aggravating such conditions as asthma and COPD. Rarely, it may depress respirations and induce apnea.

- Monitor patient's hematologic status as ordered because promethazine may cause bone marrow depression, especially when used with other known marrow-toxic agents. Assess patient for signs and symptoms of infection or bleeding.

**WARNING** Monitor patient for evidence of neuroleptic malignant syndrome, such as fever, hypertension or hypotension, involuntary motor activity, mental changes, muscle rigidity, tachycardia, and tachypnea. Be prepared to provide supportive treatment and drug therapy, as prescribed.

- Be aware that patient shouldn't have intradermal allergen tests within 72 hours of receiving promethazine because drug may significantly alter flare response.

## **PATIENT TEACHING**

- Tell patient to use a calibrated device to ensure accurate doses of promethazine syrup.
- Teach patient correct administration technique for suppository, if needed.
- Advise patient to avoid OTC drugs unless approved by prescriber.
- Instruct patient to notify prescriber immediately if she has involuntary movements and restlessness.
- Urge patient to avoid alcohol and other CNS depressants during therapy.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Suggest rinsing and use of sugarless gum or hard candy to relieve dry mouth.
- Urge patient to avoid excessive sun exposure and to use sunscreen when outdoors.

# propafenone hydrochloride

**Rythmol, Rythmol SR**

## Class and Category

*Pharmacologic class:* Sodium channel antagonist

*Therapeutic class:* Class IC antiarrhythmic

## Indications and Dosages

- *To treat life-threatening ventricular arrhythmias; to prolong time of recurrence of paroxysmal atrial fibrillation/flutter or paroxysmal supraventricular tachycardia associated with disabling symptoms in patients without structural heart disease*

### **TABLETS**

**Adults.** *Initial:* 150 mg every 8 hr; after 3 or 4 days, increased to 225 mg every 8 hr (U.S.) or 300 mg every 12 hr (Canada), as needed; after an additional 3 or 4 days, further increased to 300 mg every 8 hr, as needed.

*Maximum:* 900 mg daily.

- *To prolong time of recurrence of symptomatic atrial fibrillation in patients with episodic atrial fibrillation who do not have structural heart disease*

### **E.R. CAPSULES**

**Adults.** *Initial:* 225 mg every 12 hr, increased after 5 or more days to 325 mg every 12 hr, as needed, and further

increased to 425 mg every 12 hr, as needed.

**DOSAGE ADJUSTMENT** For patient with hepatic impairment, second- or third- AV block, or significant widening of the QRS complex, dosage may have to be reduced.

## Mechanism of Action

Prolongs recovery period after myocardial repolarization by inhibiting sodium influx through myocardial cell membranes. This action prolongs the refractory period, causing myocardial automaticity, excitability, and conduction velocity to decline.

## Contraindications

Bronchospastic disorders, such as asthma; Brugada syndrome; cardiogenic shock; concurrent use of both a CYP2D6 inhibitor and a CYP3A4 inhibitor (Rythmol SR); electrolyte imbalances; heart failure (uncontrolled); hypersensitivity to propafenone or its components; severe hypotension or obstructive pulmonary disease; sinus bradycardia or AV conduction disturbances (without artificial pacemaker)

## Interactions

### DRUGS

*amiodarone*: Possibly altered cardiac conduction and repolarization

*cimetidine, fluoxetine*: Possibly increased blood propafenone level

*CYP2D6 inhibitors and CYP3A4 inhibitors combined*: Significantly increased concentration of propafenone,

increasing risk of proarrhythmias and other adverse reactions

*digoxin*: Increased risk of digitalis toxicity

*haloperidol, imipramine, venlafaxine*: Possibly increased levels of these drugs

*lidocaine*: Possibly increased CNS adverse effects of lidocaine

*metoprolol, propranolol*: Increased blood level and half-life of these drugs

*orlistat*: Possibly decreased absorption of propafenone

*quinidine*: Decreased propafenone metabolism

*rifampin*: Possibly decreased propafenone level

*warfarin*: Increased blood warfarin level and risk of bleeding

## FOODS

*grapefruit juice*: Possibly increased blood propafenone level

## Adverse Reactions

**CNS**: Anxiety, depression, dizziness, fatigue, headache, somnolence, tremor, weakness

**CV**: Angina, **atrial flutter**, **AV block**, **bradycardia**, chest pain, edema, **heart failure**, **hypotension**, **irregular heartbeat**, palpitations, **prolonged QT interval**, tachycardia, **ventricular arrhythmias**, **worsened supraventricular arrhythmias**

**EENT**: Altered taste, blurred vision, dry mouth

**GI**: Constipation, diarrhea, flatulence, nausea, vomiting

**GU**: Decreased sperm count, hematuria

**HEME**: **Agranulocytosis**

**MS**: Muscle weakness

**RESP**: Dyspnea, rales, upper respiratory tract infection, wheezes

**SKIN:** Ecchymosis, rash

**Other:** Elevated blood alkaline phosphatase, exacerbation of myasthenia gravis, flu-like symptoms, positive ANA titers

## **Childbearing Considerations**

### **PREGNANCY**

- It is not known if drug can cause fetal harm. However, other antiarrhythmic agents have caused fetal/neonatal arrhythmias when given during pregnancy.
- Fetal/neonatal monitoring for arrhythmia is recommended during and after drug therapy in pregnant women.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### **LABOR & DELIVERY**

- Increased risk of arrhythmias during labor and delivery.

### **LACTATION**

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### **REPRODUCTION**

- Drug may transiently impair spermatogenesis in male patients.

## **Nursing Considerations**

- Assess patient for electrolyte imbalances, such as hyperkalemia, before starting propafenone or any antiarrhythmic to reduce risk of adverse cardiac reactions.

- Use propafenone cautiously in patients with heart failure or myocardial dysfunction because beta-blocking activity may further depress myocardial contractility.
- Use cautiously in patients with renal impairment because about 50% of the drug's metabolites are excreted in the urine, increasing risk of propafenone overdose.
- Monitor ECG tracings, blood pressure, and pulse rate, particularly at start of therapy and with dosage increases. Expect propafenone to be discontinued if Brugada syndrome is confirmed with ECG changes.
- Monitor patient for signs of infection such as fever, sore throat, or chills because propafenone may cause agranulocytosis, particularly during the initial 3 months of therapy. If present, notify prescriber.

## **PATIENT TEACHING**

- Instruct patient to take a missed dose if she remembers within 4 hours; otherwise, tell her to skip missed dose and to resume the regular dosing schedule.
- Advise patient not to stop propafenone or change dosage without asking prescriber.
- Urge patient to carry medical identification showing she takes propafenone.
- Advise patient to avoid hazardous activities until drug's CNS effects are known.
- Urge patient to increase fluid intake and dietary fiber if she becomes constipated.
- Explain that drug may cause an unusual taste. Advise patient to notify prescriber if taste interferes with compliance.
- Tell patient to notify prescriber promptly of any signs of infection such as fever, sore throat, or chills.

**propantheline bromide**

**Pro-Banthine, Propanthel (CAN)**

---

## Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Antiulcer

## Indications and Dosages

➤ *As adjunct to treat peptic ulcer disease*

### TABLETS

**Adults.** 15 mg three times a day before meals and 30 mg at bedtime, adjusted as needed and tolerated. *Maximum:* 120 mg daily.

***DOSAGE ADJUSTMENT*** For elderly patients with mild symptoms or patients of below-average weight, dosage possibly reduced to 7.5 mg three times a day or four times a day.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6 hr

## Mechanism of Action

Prevents the neurotransmitter acetyl- choline from combining with receptors on post- ganglionic parasympathetic nerve terminal, thereby reducing smooth-muscle spasms in the GI system, slowing GI motility, and inhibiting gastric acid secretion. All these effects help to heal peptic ulcers.

## Contraindications

Glaucoma, hemorrhage accompanied by cardiovascular hemodynamic instability, hypersensitivity to propantheline or its components, myasthenia gravis, obstructive GI or urinary disease, severe ulcerative colitis or toxic megacolon complicating ulcerative colitis

## Interactions

### DRUGS

*anticholinergics given concurrently with corticosteroids:*

Possibly increased intraocular pressure

*antihistamines, belladonna alkaloids, narcotic analgesics such as meperidine, phenothiazines, synthetic and semisynthetic anticholinergic agents, type antiarrhythmics (disopyramide, procainamide, quinidine), tricyclic*

*antidepressants or other psychoactive drugs:* Excessive cholinergic blockade

*digoxin:* Possibly digitalis toxicity

*opioid analgesics:* Increased risk of severe constipation and urine retention

*phenothiazines:* Possibly decreased antipsychotic effects; increased risk of sedation

## Adverse Reactions

**CNS:** Dizziness, excitement, insomnia, nervousness, paradoxical CNS stimulation

**CV:** Palpitations, tachycardia

**EENT:** Blurred vision; dry mouth, nose, and throat

**GI:** Constipation, dysphagia, heartburn, ileus, nausea, vomiting

**GU:** Impotence, urinary hesitancy, urine retention

**SKIN:** Decreased sweating, dry skin, flushing

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk. However, lactation suppression may occur with this type of drug.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Don't administer propantheline within 1 hour of antacids or antidiarrheals.
- Monitor elderly patients closely; they may respond to usual dose with agitation, confusion, drowsiness, or excitement.

**WARNING** Drug can interfere with sweating reflex, increasing the risk of heatstroke.

## PATIENT TEACHING

- Instruct patient to take propantheline 30 to 60 minutes before meals and at bedtime, as prescribed.
- Inform patient that drug may cause dizziness. Urge her to avoid hazardous activities until drug's CNS effects are known.
- Encourage patient to increase fluid and fiber intake to decrease constipation. Instruct her to report persistent constipation and urine retention.
- Advise patient to avoid excessive exposure to heat to reduce risk of heat prostration and heatstroke.

- Suggest that patient relieve dry mouth with frequent rinsing and sugar-free hard candy or gum.

# propofol

## (disoprofol)

### Diprivan

## Class and Category

*Pharmacologic class:* Phenol derivative

*Therapeutic class:* Sedative-hypnotic

## Indications and Dosages

- *To provide sedation for critically ill patients in intensive care*

### I.V. INFUSION

**Adults.** *Initial:* 5 mcg/kg/min (0.3 mg/kg/h), increased in increments of 5 to 10 mcg/kg/min every 5 min until desired level of sedation is achieved. *Maintenance:* 5 to 50 mcg/kg/min or higher. *Maximum:* 4 mg/kg/hr.

***DOSAGE ADJUSTMENT*** For elderly, debilitated, or American Society of Anesthesiologists Physical Status (ASA-PS) III or IV patients, induction dose decreased and maintenance rate slower.

Route	Onset	Peak	Duration
I.V.	Within 40 sec	Unknown	3–5 min

# Mechanism of Action

Decreases cerebral blood flow, cerebral metabolic oxygen consumption, and intracranial pressure and increases cerebrovascular resistance, which may play a role in propofol's hypnotic effects.

# Incompatibilities

Don't mix propofol with other drugs before giving. Don't give propofol through same I.V. line as blood or plasma products because globular component of emulsion will aggregate.

# Contraindications

Hypersensitivity to propofol or its components, to eggs or egg products, or to soybeans or soy products

# Interactions

## DRUGS

*CNS depressants such as barbiturates, benzodiazepines, chloral hydrate, droperidol, fentanyl, meperidine,*

*morphine:* Additive CNS depressant, respiratory depressant, and hypotensive effects; possibly decreased emetic effects of opioids

*nitrous oxide, opioids, potent inhalational agents*

*(enflurane, halothane, isoflurane):* Increased anesthetic, cardiorespiratory, or sedative effects of propofol

*valproate:* Increased blood levels of propofol increasing risk of cardiorespiratory depression and sedation

## ACTIVITIES

*alcohol use:* Additive CNS depressant, respiratory depressant, and hypotensive effects

## Adverse Reactions

**CV:** Bradycardia, hypotension

**GI:** Nausea, vomiting

**MS:** Involuntary muscle movement (transient)

**RESP:** Apnea

**Other:** Anaphylaxis, injection-site burning, pain, or stinging

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Drug is not recommended for obstetrics, including cesarean section deliveries, because drug crosses the placental barrier and may cause neonatal nervous and respiratory system depression.

### LACTATION

- Drug is present in breast milk.
- Drug is not recommended during breastfeeding.

## Nursing Considerations

- Know that repeated or lengthy (greater than 3 hours) use of sedation drugs such as propofol and general anesthetics during procedures or surgeries should be avoided, if possible, in children younger than 3 years of age or in pregnant women during their third trimester, because the combined use may affect the development of children's brains.
- Use propofol cautiously in patients with cardiac disease, peripheral vascular disease, impaired cerebral circulation, or increased intracranial pressure because drug may aggravate these disorders.
- To dilute before administration, use only D<sub>5</sub>W for final solution of 2 mg/ml or more.
- Consult prescriber about pretreating injection site with 1 ml of 1% lidocaine to minimize pain, burning, or stinging that may occur. If ordered, lidocaine shouldn't be added to propofol solution in quantities greater than 20 mg/200 mg propofol because emulsion may become unstable. Giving drug through a larger vein in forearm or antecubital fossa also may minimize injection-site discomfort.
- Shake container well before using, administer drug promptly after opening, and use vial for a single patient. Use prefilled syringes within 6 hours of opening.
- Use a drop counter, syringe pump, or volumetric pump to safely control infusion rate. Don't infuse drug through filter with a pore size of less than 5 microns; doing so could cause emulsion to break down.
- Discard unused portion of propofol solution plus reservoirs, I.V. tubing, and solutions immediately after or within 12 hours of administration (6 hours if propofol was transferred from original container) to prevent bacterial growth in stagnant solution. Also, protect solution from light.
- Dosage must be tapered before stopping therapy. Stopping abruptly will cause rapid awakening, anxiety, agitation and resistance to mechanical ventilation.
- Expect patient to recover from sedation within 8 minutes.

**WARNING** Monitor patient for propofol infusion syndrome, especially with prolonged high-dose infusions. It may cause severe metabolic acidosis, hyperkalemia, lipemia, rhabdomyolysis, hepatomegaly and cardiac and renal failure. Alert prescriber at once and be prepared to provide emergency supportive care as ordered.

## PATIENT TEACHING

- Urge patient and family to voice concerns and ask questions before administration.
- Reassure patient that she'll be monitored closely during administration and that vital functions will be supported as needed.
- Inform patient and family that caution is required when performing activities requiring mental alertness, such as driving, because mental alertness may be impaired for some time after general anesthesia or sedation such as propofol has been given.

## propranolol hydrochloride

**Detensol (CAN), Inderal LA, Inderal XL, InnoPran XL**

### Class and Category

*Pharmacologic class:* Beta-adrenergic blocker

*Therapeutic class:* Antianginal, antiarrhythmic, antihypertensive, anti-MI, antimigraine, antitremor, hypertrophic cardiomyopathy, and pheochromocytoma therapy adjunct

### Indications and Dosages

➤ *To manage hypertension*

#### **E.R. CAPSULES (INDERAL-LA)**

**Adults.** 60 to 320 mg taken once a day in the morning or evening.

## **XL CAPSULES (INDERAL XL, INNOPRAN XL)**

**Adults.** *Initial:* 80 mg once daily at bedtime, increased, as needed, to 120 mg once daily at bedtime.

## **ORAL SOLUTION, TABLETS**

**Adults.** *Initial:* 40 mg twice daily, increased gradually to 120 to 240 mg daily, as needed. *Maximum:* 640 mg daily.

**Children.** *Initial:* 0.5 to 1 mg/kg daily in divided doses twice daily to four times a day, adjusted as needed.

*Maintenance:* 2 to 4 mg/kg daily in divided doses twice daily.

➤ *To treat chronic angina*

## **E.R. CAPSULES (INDERAL-LA)**

**Adults.** 60 to 320 mg taken once a day in the morning or evening.

## **ORAL SOLUTION, TABLETS**

**Adults.** 80 to 320 mg daily in divided doses twice daily, three times a day, or four times a day.

➤ *To treat atrial fibrillation*

## **ORAL SOLUTION, TABLETS**

**Adults.** 10 to 30 mg three times a day. or four times a day, adjusted as needed.

## **I.V. INJECTION**

**Adults.** 1 to 3 mg at a rate not to exceed 1 mg/min; repeated after 2 min and again after 4 hr, as needed.

➤ *To control tremor*

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 40 mg twice daily, adjusted as needed and prescribed. *Maximum:* 320 mg daily.

- *To prevent vascular migraine headaches*

## E.R. TABLETS

**Adults.** *Initial:* 80 mg daily, increased gradually, as needed. *Maximum:* 240 mg daily.

## ORAL SOLUTION, TABLETS

**Adults.** *Initial:* 20 mg four times a day, increased gradually, as needed. *Maximum:* 240 mg daily.

- *As adjunct to treat hypertrophic subaortic stenosis*

## ORAL SOLUTION, TABLETS

**Adults.** 20 to 40 mg three times a day or four times a day before meals and at bedtime adjusted, as needed.

- *As adjunct to manage pheochromocytoma*

## ORAL SOLUTION, TABLETS

**Adults.** For operable tumors, 60 mg in divided doses for 3 days before surgery, concurrently with an alpha blocker. For inoperable tumors, 30 mg daily in divided doses concurrently with an alpha blocker.

- *To prevent MI*

## ORAL SOLUTION, TABLETS

**Adults.** 180 to 240 mg daily in divided doses.

***DOSAGE ADJUSTMENT*** Dosage increased or decreased for elderly patients, depending on sensitivity to propranolol.

Route	Onset	Peak	Duration
P.O.	Unknown	1–1.5 hr*	Unknown

\* For regular-release form; unknown for E.R. form.

## Mechanism of Action

Through beta-blocking action, propranolol:

- prevents arterial dilation and inhibits renin secretion, resulting in decreased blood pressure (in hypertension and pheochromocytoma) and relief of migraine headaches
- decreases heart rate, which helps resolve tachyarrhythmias
- improves myocardial contractility, which helps ease symptoms of hypertrophic cardiomyopathy
- decreases myocardial oxygen demand, which helps prevent anginal pain and death of myocardial tissue.

In addition, peripheral beta-adrenergic blockade may play a role in propranolol's ability to alleviate tremor.

## Contraindications

Bronchial asthma; cardiogenic shock; decompensated heart failure; greater than first degree block, sick sinus syndrome, or sinus bradycardia unless a permanent pacemaker is in place; hypersensitivity to propranolol or any of its components

## Interactions

### DRUGS

*alpha blockers (prazosin):* May cause prolongation of first dose hypotension and syncope

*cholestyramine, colestipol*: Significantly reduces plasma concentrations of propranolol, which may result in loss of effectiveness

*clonidine*: Possibly antagonized antihypertensive effects of clonidine

*CYP1A2 inducers (montelukast, phenytoin), CYP2C19 inducers (rifampin)*: Decreased plasma levels of propranolol resulting in loss of effectiveness

*CYP1A2 inhibitors (ciprofloxacin, enoxamine, fluvoxamine), CYP2D6 inhibitors (bupropion, fluoxetine, paroxetine, quinidine)*: Increased exposure to propranolol increasing risks of adverse reactions such as bradycardia and hypotension

*dobutamine*: Reduced sensitivity to dobutamine stress echocardiography in patients undergoing evaluation for myocardial ischemia

*MAO inhibitors, tricyclic antidepressants*: Increased risk of significant hypertension

*NSAIDs*: Possibly decreased hypotensive effects

*propafenone*: Increased blood level and adverse reactions such as bradycardia and postural hypotension

*warfarin*: Increased risk of bleeding

## **ACTIVITIES**

*alcohol*: Possibly decreased or increased plasma propranolol level

*nicotine chewing gum, smoking cessation, smoking*

*deterrents*: Possibly decreased therapeutic effects of propranolol

## **Adverse Reactions**

**CNS**: Anxiety, depression, dizziness, drowsiness, fatigue, fever, insomnia, lethargy, nervousness, weakness

**CV:** AV conduction disorders, bradycardia, cold limbs, heart failure, hypotension

**EENT:** Dry eyes, laryngospasm, nasal congestion, pharyngitis

**GI:** Abdominal pain, constipation, diarrhea, nausea, vomiting

**GU:** Impotence, Peyronie's disease, sexual dysfunction

**HEME:** Agranulocytosis, nonthrombocytopenic purpura, thrombocytopenic purpura

**MS:** Muscle weakness, myopathy, myotonia

**RESP:** Bronchospasm, dyspnea, respiratory distress, wheezing

**SKIN:** Alopecia, erythema multiforme, erythematous rash, exfoliative dermatitis, psoriasiform rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, flu-like symptoms, systemic lupus-like reaction

## Childbearing Considerations

### PREGNANCY

- Drug may have the potential to cause fetal harm such as congenital anomalies and intrauterine growth retardation.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LABOR & DELIVERY

- Neonates born to mothers who received drug at parturition may exhibit bradycardia, hypoglycemia, and/or respiratory depression.
- Neonates need to be monitored closely for adverse effects.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, mother should monitor infant for low pulse rate or signs and symptoms of low blood glucose level as well as respiratory depression.

## Nursing Considerations

- Use propranolol cautiously in patients with bronchospastic lung disease because it may induce asthmatic attack, and in patients with underlying skeletal muscle disease; isolated reports of myopathy and myotonia have occurred with propranolol use.
- Monitor blood pressure, apical and radial pulses, fluid intake and output, daily weight, respiration, and circulation in extremities before and during therapy.
- Give I.V. injection at no more than 1 mg/min.

**WARNING** Monitor ECG continuously, as ordered, when giving I.V. injection. Have emergency drugs and equipment available in case of hypotension or cardiac arrest.

- Protect injection solution from light.
- Because drug's negative inotropic effect can depress cardiac output, monitor cardiac output in patients with heart failure, particularly those with severely compromised left ventricular dysfunction.
- Be aware that propranolol can mask tachycardia in hyperthyroidism and that abrupt withdrawal in patients with hyperthyroidism or thyrotoxicosis can cause thyroid storm.
- Monitor diabetic patient taking an antidiabetic because propranolol can prolong hypoglycemia or promote hyperglycemia. It also can mask signs of hypoglycemia, especially tachycardia, palpitations, and tremor, but it doesn't suppress diaphoresis or hypertensive response to hypoglycemia.

**WARNING** Be aware that stopping drug abruptly, even for surgery, may cause myocardial ischemia, MI, ventricular arrhythmias, or severe hypertension, especially in patients with cardiac disease. However, be aware that the heart may not be able to respond to reflex adrenergic stimuli normally during surgery, which increases the risks of general anesthesia and surgical procedures. It also may cause increased intraocular pressure to return. Dosage should be reduced gradually.

## **PATIENT TEACHING**

- Instruct patient to take propranolol at the same time every day.
- Caution patient not to change dosage without consulting prescriber and not to stop taking drug abruptly.
- Advise patient to notify prescriber immediately if she has shortness of breath.
- Instruct diabetic patient to check blood glucose level and urine for ketones regularly.
- Advise patient to consult prescriber before taking OTC drugs, especially cold products.
- Urge patient to avoid hazardous activities until CNS effects of drug are known.
- Advise smoker to notify prescriber immediately if she stops smoking because cessation may decrease drug metabolism, calling for dosage adjustments.
- Tell patient to notify prescriber if she is or could be pregnant because drug may have to be discontinued.

**propylthiouracil**

**(PTU)**

# Propyl-Thyracil (CAN)

## Class and Category

*Pharmacologic class:* Thyroid hormone antagonist

*Therapeutic class:* Antithyroid

## Indications and Dosages

- *To treat Graves' disease with hyperthyroidism or toxic multinodular goiter in patients who are intolerant of methimazole and for whom radioactive iodine therapy or surgery is not an appropriate treatment option; to improve symptoms of hyperthyroidism in preparation for radioactive iodine therapy or thyroidectomy in patients who are intolerant of methimazole*

## TABLETS

**Adults.** *Initial:* 300 to 900 mg daily in 3 divided doses until patient becomes euthyroid. *Maintenance:* 100 to 150 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	17 wk	Unknown

## Mechanism of Action

Inhibits conversion of peripheral thyroxine to triiodothyronine by interfering with incorporation of iodide into thyroglobulin; drug remains iodinated and degraded in thyroid gland. Diversion of oxidized iodine away from

thyroglobulin diminishes thyroid hormone synthesis and levels of circulating thyroid hormone.

## Contraindications

Hypersensitivity to propylthiouracil or its components

## Interactions

### DRUGS

*amiodarone, iodinated glycerol, iodine, potassium iodide:* Decreased efficacy of propylthiouracil

*beta blockers, digoxin, theophylline:* Plasma levels altered during hyperthyroidism but when patient becomes euthyroid dosage adjusted

*oral anticoagulants:* Possibly enhanced anticoagulant effect

*sodium iodide 131 (radioactive iodine, <sup>131</sup>I):* Decreased thyroid uptake of <sup>131</sup>I

## Adverse Reactions

**CNS:** Dizziness, drowsiness, headache, neuritis, paresthesia, peripheral neuropathy, vertigo

**CV:** Edema, periarteritis, vasculitis

**EENT:** Taste loss or perversion

**ENDO:** Hypothyroidism

**GI:** Abdominal pain, **acute liver failure**, epigastric distress, **hepatitis**, **hepatotoxicity**, nausea, vomiting

**GU:** **Acute renal failure**, glomerulonephritis, **nephritis**

**HEME:** **Agranulocytosis**, **aplastic anemia**, **bleeding**, **granulopenia**, **hypoprothrombinemia**, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, joint redness or swelling, myalgia

**RESP:** Alveolar hemorrhage, interstitial pneumonitis, pulmonary infiltrates

**SKIN:** Alopecia, erythema nodosum, exfoliative dermatitis, leukocytoclastic vasculitis, pruritus, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, ulceration, urticaria

**Other:** Drug fever, lupus-like symptoms

## Childbearing Considerations

### PREGNANCY

- Drug may cause fetal harm such as cretinism, fetal goiter, liver damage.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Ensure that patient, parents, or caregivers have been informed about the risk of liver failure, before administering propylthiouracil.
- Monitor complete blood count (CBC), prothrombin time (PT), and thyroid function in patients taking propylthiouracil. Elevated serum triiodothyronine (T<sub>3</sub>) level may be the sole indicator of inadequate treatment.
- Expect to stop drug 3 to 4 days before <sup>131</sup>I treatment to prevent decreased thyroid uptake of <sup>131</sup>I. Therapy may be resumed 3 to 5 days after radiation, if needed.
- Know that serum T<sub>3</sub> and thyroxine levels should decrease after about 3 weeks of therapy.

- Expect to decrease beta blocker or theophylline dosage once patient is euthyroid, as ordered.
- Monitor liver enzymes, especially during first 6 months of therapy, because drug may cause liver failure, need for liver transplant, or death. Expect to stop drug at first sign of liver dysfunction (easy bruising, fatigue, itching, jaundice, loss of appetite, vague abdominal pain, and weakness) and obtain liver enzymes, as ordered.
- Be aware that propylthiouracil may be the treatment of choice when an antithyroid drug is indicated during or just prior to the first trimester of pregnancy. However, after the first trimester of pregnancy, expect an alternative antithyroid medication to be prescribed because drug crosses the placenta and can cause fetal cretinism and goiter.

**WARNING** Be aware that cases of vasculitis resulting in severe complications and death have occurred in patients receiving propylthiouracil. If suspected, notify prescriber immediately and expect drug to be discontinued. For more severe cases, also expect patient to receive corticosteroids, immunosuppressant therapy, and plasmapheresis, as needed.

## **PATIENT TEACHING**

- Instruct patient to take drug with meals to decrease risk of adverse GI reactions.
- Urge patient to avoid dietary sources of iodine, such as iodized salt and shellfish.
- Tell patient to check pulse rate and weight daily and to report increased heart rate and excessive weight loss to prescriber.
- Urge patient to report signs and symptoms of infection, such as fever and sore throat.
- Instruct patient to notify prescriber immediately if she becomes pregnant.
- Advise patient to report signs and symptoms of hypothyroidism, such as cold intolerance, depression, and increased fatigue.
- Tell patient to ask prescriber before using OTC cold drugs (some contain iodides).

- Advise patient to notify prescriber immediately if he has easy bruising, fatigue, itching, loss of appetite, vague right upper quadrant abdominal pain, weakness, or yellowing of eyes or skin.

## protamine sulfate

### Class and Category

*Pharmacologic class:* Heparin antagonist

*Therapeutic class:* Heparin antidote

### Indications and Dosages

- *To treat heparin toxicity or hemorrhage associated with heparin therapy*

#### I.V. INJECTION

**Adults.** Dosage dependent on lapse of time from when severe bleeding begins in relationship to when heparin dosage was given.

*For severe bleeding occurring a few minutes after I.V. injection of heparin:* 1 mg for every 100 units of heparin administered. *For severe bleeding occurring 30 min after I.V. injection of heparin:* 0.5 mg for every 100 units of heparin given. *For severe bleeding occurring 2 hr or more after I.V. injection of heparin:* 0.25 to 0.375 mg for every 100 units of heparin given. *For severe bleeding after subcutaneous injection of heparin:* 1 to 1.5 mg for every 100 units of heparin given. I.V. injection given very slowly over 10 min, not to exceed 50 mg in any 10-min period.

Route	Onset	Peak	Duration
I.V.	5 min	Unknown	2 hr

## Mechanism of Action

Neutralizes anticoagulant activity. A strong basic polypeptide, protamine combines with strongly acidic heparin complex to form an inactive stable salt, thereby neutralizing anticoagulant activity of both drugs.

## Incompatibilities

Don't mix protamine sulfate in same syringe with other drugs unless they're known to be compatible. Several cephalosporins, penicillins, and other antibiotics are incompatible.

## Contraindications

Allergy to fish, hypersensitivity to protamine or its components

## Interactions

### DRUGS

*heparin*: Neutralized anticoagulant effect of heparin

*insulin*: Prolongs absorption of insulin

*low molecular weight heparins*: Incomplete neutralization of anticoagulant activity of low molecular weight heparin

## Adverse Reactions

**CNS:** Weakness

**CV:** Bradycardia, hypertension, hypotension, shock

**GI:** Nausea, vomiting

**HEME:** Unusual bleeding or bruising

**RESP:** Dyspnea, pulmonary edema (noncardiogenic), pulmonary hypertension

**SKIN:** Flushing, sensation of warmth

**Other:** Anaphylaxis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug may cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Expect to administer I.V. protamine undiluted. However, dilute drug if needed (for patients other than neonates) with 5 ml of bacteriostatic water for injection containing 0.9% benzyl alcohol. For neonates, reconstitute with preservative-free sterile water for injection.
- Inject drug slowly at 5 mg/min; administer no more than 50 mg in 10 minutes or 100 mg in 2 hours.

**WARNING** Be aware that rapid delivery may cause severe hypotension and anaphylaxis.

- Be prepared to obtain coagulation studies (APTT, activated clotting time) 5 to 15 minutes after giving drug and to repeat them in 2 to 8 hours to detect heparin-rebound hypotension, shock, and bleeding.
- Monitor vital signs, hemodynamic parameters, and fluid intake and output, and assess for flushing sensation.
- Have fluids—epinephrine 1:1,000, dobutamine, or dopamine—available for allergic or hypotensive reactions.
- Be aware that men with vasectomy have an increased risk of hypersensitivity reaction because of possible accumulation of antiprotamine antibodies.

## PATIENT TEACHING

- Instruct patient to report adverse reactions immediately.

## protriptyline hydrochloride

### **Triptil (CAN), Vivactil**

## Class and Category

*Pharmacologic class:* Tricyclic antidepressant

*Therapeutic class:* Antidepressant

## Indications and Dosages

➤ *To treat depression*

### **TABLETS**

**Adults.** *Initial:* 5 to 10 mg three times a day or four times a day, increased every wk by 10 mg daily, as needed with

dosage increased made in morning dose. *Maximum:* 60 mg daily.

***DOSAGE ADJUSTMENT*** For adolescents and elderly patients, initial dosage limited to 5 mg three times a day, then adjusted, as needed.

Route	Onset	Peak	Duration
P.O.	2-3 wk	Unknown	Unknown

## Mechanism of Action

May block reuptake of norepinephrine and serotonin (and possibly other neurotransmitters) at neuronal membranes, thus enhancing their effects at postsynaptic receptors. These neurotransmitters may play a role in relieving depression symptoms.

## Contraindications

Acute recovery phase after MI, concurrent therapy with cisapride, hypersensitivity to protriptyline or its components, use within 14 days of MAO inhibitor therapy

## Interactions

### DRUGS

*anticholinergic agents, neuroleptic drugs:* Increased risk of hyperpyrexia, especially in hot weather

*anticholinergics, sympathomimetic drugs (epinephrine)*

*combined with local anesthetics:* Altered dosage requirements

*cimetidine:* Possible reduced metabolism of protriptyline with increased blood levels

*CNS depressants:* Possible increased CNS depressant effects

CYP2D6 substrates such as other antidepressants, phenothiazines, selective serotonin reuptake inhibitors, type I C *antiarrhythmics*: Possibly increased blood protriptyline levels leading to toxicity unexpectedly  
*tramadol*: Increased seizure risk

## ACTIVITIES

*alcohol use*: Possibly increased CNS depression alcohol

## Adverse Reactions

**CNS:** Agitation, ataxia, confusion, **CVA**, dizziness, drowsiness, exacerbation of psychosis, extrapyramidal reactions, fatigue, lack of coordination, paresthesia, peripheral neuropathy, **suicidal ideation**, tremor, weakness

**CV:** **Arrhythmias, including heart block**; hypertension; **hypotension**; **MI**; orthostatic hypotension; palpitations; tachycardia

**EENT:** Angle closure glaucoma, black tongue, blurred vision, dry mouth, increased intraocular pressure, lacrimation, stomatitis, tongue swelling

**ENDO:** Hyperglycemia, **hypoglycemia**

**GI:** Abdominal cramps, anorexia, constipation, diarrhea, epigastric discomfort, hepatic dysfunction, nausea, vomiting

**GU:** Impotence, libido changes, nocturia, urinary frequency and hesitancy, urine retention

**SKIN:** Diaphoresis, petechiae, photosensitivity, rash, urticaria

**Other:** **Angioedema**, weight gain or loss

# Childbearing Considerations

## PREGNANCY

- It is not known if drug may cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Use protriptyline cautiously in patients with a history of seizures because drug can lower seizure threshold.
- Use cautiously in patients with a history of urine retention or increased intraocular pressure because of drug's autonomic activity.

**WARNING** Avoid giving protriptyline with an MAO inhibitor. If patient is being switched from an MAO inhibitor to protriptyline, make sure MAO inhibitor has been discontinued for 14 days before starting protriptyline.

- Watch patients closely (especially children, adolescents, and young adults) for suicidal tendencies, particularly when therapy starts or dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

## PATIENT TEACHING

- Inform patient that protriptyline therapy may take several weeks to reach full effect.

- Advise patient that drug may cause mild pupillary dilation, which may lead to an episode of acute closure glaucoma. Encourage patient to have an eye exam before starting therapy to see if he is at risk.
- Instruct patient to avoid hazardous activities until drug's CNS effects are known.
- Advise patient to change position slowly to minimize orthostatic hypotension.
- Urge patient to avoid alcohol while taking drug.
- Suggest drinking water and using sugarless gum or hard candy to relieve dry mouth.
- Advise patient to avoid sunlight and tanning booths and to wear protective clothing, a hat, and sunscreen when outdoors.
- Instruct diabetic patient to check blood glucose level frequently during first few weeks of protriptyline therapy.
- Urge family or caregiver to watch patient for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child, teenager, or young adult.

## pyridostigmine bromide

**Mestinon, Mestinon-SR (CAN),  
Mestinon Timespans, Regonol**

### Class and Category

*Pharmacologic class:* Cholinesterase inhibitor

*Therapeutic class:* Muscle stimulant

### Indications and Dosages

➤ *To treat symptoms of myasthenia gravis*

## E.R. TABLETS

**Adults and adolescents.** 180 to 540 mg once or twice daily (at least 6 hr between doses).

## ORAL SOLUTION, TABLETS

**Adults and adolescents.** Highly individualized. *Average dose:* 600 mg daily spaced to provide maximum relief when maximum strength is needed. *For mild symptoms:* 60 mg to 360 mg daily, spaced to provide maximum relief. *For severe symptoms:* As high as 1,500 mg daily, spaced to provide maximum relief.

➤ *To reverse the effects of neuromuscular blockers*

## I.V. INJECTION

**Adults.** 0.1 to 0.25 mg/kg no faster than 1 mg/min immediately before or with 0.6 to 1.2 mg of I.V. atropine.

***DOSAGE ADJUSTMENT*** Dosage possibly reduced for patients with renal impairment.

Route	Onset	Peak	Duration
P.O.	30-45 min	1-2 hr	3-6 hr
P.O. (E.R.)	30-60 min	1-2 hr	6-12 hr
I.V.	2-5 min	Unknown	2-4 hr
I.M.	15 min	Unknown	2-4 hr

## Mechanism of Action

Improves muscle strength compromised by myasthenia gravis or neuromuscular blockade by competing with acetylcholine for its binding site on acetylcholinesterase. This action potentiates the effects of acetylcholine on skeletal muscle and the GI tract. Inhibited destruction of

acetylcholine allows freer transmission of nerve impulses across the neuromuscular junction.

## Contraindications

Hypersensitivity to pyridostigmine or its components,  
mechanical obstruction of GI or urinary tract

## Interactions

### DRUGS

*4-aminopyridine*: Delayed onset of action of pyridostigmine  
*aminoglycosides, bacitracin, colistin, magensium salts, polymyxin B, sodium colistimethate, tetracyclines*: Possible antagonized effects of pyridostigmine  
*quinidine*: Possibly recurrent paralysis

## Adverse Reactions

**EENT**: Increased salivation, lacrimation, miosis

**GI**: Abdominal cramps, diarrhea, increased peristalsis, nausea, vomiting

**GU**: Urinary frequency, incontinence, or urgency

**MS**: Fasciculations, muscle spasms or weakness

**RESP**: Increased tracheobronchial secretions

**SKIN**: Diaphoresis

## Childbearing Considerations

### PREGNANCY

- It is not known if drug may cause fetal harm.

- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use pyridostigmine cautiously in patients with renal disease because drug is mainly excreted unchanged by kidneys. Monitor BUN and serum creatinine levels.

**WARNING** Maintain a rigid dosing schedule because a missed or late dose can precipitate myasthenic crisis.

- Observe for cholinergic reactions when administering drug I.V. or I.M.

**WARNING** Pyridostigmine overdose may obscure diagnosis of myasthenic crisis because main symptom in both is muscle weakness. Treat cholinergic crisis by stopping anticholinesterase, giving atropine as prescribed, and helping with endotracheal intubation and mechanical ventilation, if needed.

- Be aware that reversal of neuromuscular blockade usually occurs in 15 to 30 minutes. Be prepared to maintain patent airway and ventilation until normal voluntary respiration returns completely. Assess respiratory measurements and muscle tone with peripheral nerve stimulator device, as indicated.

## PATIENT TEACHING

- Instruct patient to take pyridostigmine as directed and on schedule. Explain that a late or missed dose can precipitate a crisis. Suggest the use

of a battery-operated alarm clock as a reminder.

- Tell patient to take drug with a full glass of water or with food or milk if GI distress occurs.
- Warn patient not to crush or chew E.R. tablets.
- Ask patient to record pyridostigmine dosage, times taken, and drug effects to help determine optimal dosage and schedule.
- Urge patient to carry medical identification describing her condition and drug regimen.

## Q R S

### quetiapine fumarate

**Seroquel, Seroquel XR**

#### Class and Category

*Pharmacologic class:* Dibenzothiazepine derivative

*Therapeutic class:* Antipsychotic

#### Indications and Dosages

➤ *To treat schizophrenia*

##### **TABLETS**

**Adults.** *Initial:* 25 mg twice daily on day 1. Increased by 25 to 50 mg twice daily or three times a day on days 2 and 3, then to 300 to 400 mg daily by day 4, in divided doses twice daily or three times a day. Increased every 2 days or more in increments of 25 to 50 mg twice daily, as needed.

*Maximum:* 750 mg daily.

**Adolescents ages 13 to 17 years.** *Initial:* 25 mg twice daily on day 1; 50 mg twice daily on day 2; 100 mg twice daily on day 3; 150 mg twice daily on day 4; 200 mg twice daily on day 5. Increased further in increments no greater than 100 mg/day and no higher than a total daily dose of 800 mg, as needed.

## **E.R. TABLETS**

**Adults.** *Initial:* 300 mg once daily in evening. Dosage increased daily in increments up to 300 mg, as needed. *Maximum:* 800 mg daily.

**Adolescents age 13 to 17 years.** *Initial:* 50 mg daily on day 1; 100 mg daily on day 2; 200 mg daily on day 3; 300 mg daily on day 4; 400 mg daily on day 5. Increased further in increments no greater than 100 mg/day and no higher than a total daily dose of 800 mg, as needed.

- *To maintain schizophrenia therapy with monotherapy*

## **E.R. TABLETS, TABLETS**

**Adults.** 400 to 800 mg daily after dosage has been titrated to usual dosage. *Maximum:* 800 mg daily.

- *To treat depressive episodes in bipolar disorder*

## **E.R. TABLETS, TABLETS**

**Adults.** *Initial:* On day 1, 50 mg once at bedtime; day 2, 100 mg once at bedtime; day 3, 200 mg once at bedtime; day 4, 300 mg once at bedtime. *Maintenance:* 300 mg once daily at bedtime.

- *As adjunct therapy with antidepressants to treat major depressive disorder*

## **E.R. TABLETS**

**Adults.** *Initial:* 50 mg once daily in evening, increased to 150 mg once daily in evening on day 3. *Maintenance:* 150 to 300 mg daily. *Maximum:* 300 mg daily in evening.

- *To treat acute manic episodes in bipolar I disorder as monotherapy*

## **TABLETS**

**Adults.** *Initial:* 50 mg twice daily on day 1; 100 mg twice daily on day 2; 150 mg twice daily on day 3; 200 mg twice daily on day 4. Increased further in increments of no greater than 200 up to 800 mg/day by day 6, if needed.

**Children age 10 and over.** *Initial:* 25 mg twice daily on day 1; 50 mg twice daily on day 2; 100 mg twice daily on day 3; 150 mg twice daily on day 4; 200 mg twice daily on day 5. Further increased in increments no greater than 100 up to 600 mg/day, as needed.

## **E.R. TABLETS**

**Children age 10 and over.** *Initial:* 50 mg daily on day 1; 100 mg daily on day 2; 200 mg daily on day 3; 300 mg daily on day 4; 400 mg daily on day 5. Further increased in increments no greater than 100 up to 600 mg/day, as needed.

- *To treat acute manic or mixed episodes in bipolar I disorder as adjunct with lithium or divalproex or as monotherapy*

## **E.R. TABLETS**

**Adults.** *Initial:* 300 mg once daily in evening on day 1, followed by 600 mg once daily in evening on day 2 and between 400 and 800 mg daily on day 3 and thereafter. *Maintenance:* 400 to 800 mg/day. *Maximum:* 800 mg daily.

- *To treat acute manic episodes in bipolar I disorder as adjunct with lithium or divalpoex or as monotherapy*

## **TABLETS**

**Adults.** *Initial:* 50 mg twice daily on day 1; 100 mg twice daily on day 2; 150 mg twice daily on day 3; 200 mg twice daily on day 4. Increased further in increments of no greater than 200 up to 800 mg/day by day 6, if needed.

- *As adjunct to divalproex or lithium therapy to maintain treatment in bipolar I disorder*

## **E.R. TABLETS, TABLETS**

**Adults.** 400 to 800 mg daily given in 2 divided doses.

*Maximum:* 800 mg daily.

***DOSAGE ADJUSTMENT*** For patients with hepatic impairment, initial dosage no higher than 25 mg once daily for immediate-release form and 50 mg once daily for extended-release form and increased in increments of 25 mg/day for immediate-release form and 50 mg/day for extended-release form depending on response and tolerance. For elderly patients, initial dosage of either form reduced to 50 mg/day and dose increased in increments of 50 mg/day, as needed.

## **Mechanism of Action**

May produce antipsychotic effects by interfering with dopamine binding to dopamine type 2 (D<sub>2</sub>)-receptor sites in the brain and by antagonizing serotonin 5-HT<sub>2</sub>, dopamine type 1 (D<sub>1</sub>), histamine H<sub>1</sub>, and adrenergic alpha<sub>1</sub> and alpha<sub>2</sub> receptors.

## **Contraindications**

Hypersensitivity to quetiapine or its components

## **Interactions**

### **DRUGS**

*antihypertensives:* Increased risk of hypotension

*CNS depressants:* Possibly increased CNS depression

*CYP3A4 inducers (avasimibe, carbamazepine, phenytoin, rifampin, St. John's wort):* Decreased exposure of quetiapine with decreased effectiveness  
*CYP3A4 inhibitors (ketoconazole, indinavir, itraconazole, nefazodone, ritonavir):* Increased exposure of quetiapine increasing risk of adverse reactions  
*dopamine agonists, levodopa:* Possibly antagonized effects of these drugs

## ACTIVITIES

*alcohol use:* Possibly enhanced CNS depression

## Adverse Reactions

**CNS:** Depression, dizziness, drowsiness, dystonia, extrapyramidal reactions, hypertonia, **hypothermia**, lethargy, restless leg syndrome, retrograde amnesia, somnolence, **suicidal ideation**, tardive dyskinesia  
**CV:** **Cardiomyopathy**, hypercholesterolemia, **myocarditis**, orthostatic hypotension, palpitations, **prolongation of QT interval**

**EENT:** Dry mouth, nasal congestion, pharyngitis, rhinitis

**ENDO:** Galactorrhea, hyperglycemia, syndrome of inappropriate ADH secretion

**GI:** Anorexia, constipation, indigestion, **pancreatitis**

**GU:** Nocturnal enuresis

**HEME:** **Agranulocytosis, leukopenia, neutropenia, thrombocytopenia**

**MS:** Dysarthria, muscle weakness, **rhabdomyolysis**

**RESP:** Cough, dyspnea

**SKIN:** Diaphoresis, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Anaphylaxis, drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms,

hyponatremia, weight gain

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.
- Drug may cause fetal harm if exposed in the third trimester increasing risk for extrapyramidal and/or withdrawal symptoms following delivery.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Drug may increase prolactin levels, which may lead to a reversible reduction in fertility in female patients.

## Nursing Considerations

**WARNING** Know that quetiapine shouldn't be used for elderly patients with dementia-related psychosis because drug increases the risk of death in these patients.

- Know that quetiapine should not be given to patients who have a history of cardiac arrhythmias, such as bradycardia, or who experience hypokalemia or hypomagnesemia. The drug also should not be used with other drugs that prolong the QT interval or in a patient who has a congenital prolongation of the QT interval because quetiapine may increase the QT interval, which may increase the risk of torsades de pointes and/or sudden death.

- Use quetiapine cautiously in patients who have a history of cardiovascular disease, a family history of QT prolongation, or in patients who are elderly or take medications that may cause an electrolyte imbalance, such as diuretics, or who have congestive heart failure or heart hypertrophy, because these factors may increase the risk of a prolonged QT interval. Also use cautiously in cardiac patients because quetiapine may cause orthostatic hypotension.
- Monitor patients (particularly children and young adults) closely for suicidal tendencies, especially when therapy starts or dosage changes, because depression may worsen temporarily during these times.

**WARNING** Monitor patient taking quetiapine for predisposing factors for neuroleptic malignant syndrome, such as dehydration, heat stress, organic brain disease, and physical exhaustion. Neuroleptic malignant syndrome includes altered mental status, autonomic instability (which may include arrhythmias, blood pressure abnormalities, diaphoresis, irregular pulse, or tachycardia), hyperpyrexia, and muscle rigidity.

- Monitor patient for signs of tardive dyskinesia, a potentially irreversible complication characterized by involuntary, dyskinetic movements of eyelids, face, jaw, mouth, or tongue. Notify prescriber if such signs develop, because quetiapine therapy may need to be stopped.
- Monitor patient for orthostatic hypotension, especially during initial dosage titration period. Be prepared to correct underlying conditions, such as dehydration and hypovolemia, before starting quetiapine therapy, as prescribed.
- Monitor patient for prolonged abnormal muscle contractions, especially during the first few days of quetiapine therapy, in male patients and in younger patients.
- Assess patient for hypothyroidism because drug can cause dose-dependent decreases in total and free thyroxine ( $T_4$ ) levels.
- Monitor laboratory results during first 3 weeks of therapy for transient elevations in hepatic enzyme levels. Notify prescriber if they persist or worsen.
- Monitor patient's blood glucose and lipid levels routinely, as ordered, because drug increases the risk of hyperglycemia and hypercholesterolemia.

- Check CBC often during the first few months of therapy, as ordered, in patients with a low white blood cell count or a history of drug-induced hematologic problems. If counts drop or patient develops a fever or other signs of infection, notify prescriber and expect to discontinue drug and provide supportive care.
- Institute fall precautions, because patients receiving quetiapine have a greater risk of falling.
- Expect to gradually taper off quetiapine therapy when discontinued, as ordered, to avoid acute withdrawal symptoms such as insomnia, nausea, and vomiting.

## PATIENT TEACHING

- Instruct patient to take quetiapine with food to reduce stomach upset.
- Advise patient not to stop taking quetiapine suddenly because doing so may exacerbate his symptoms or produce withdrawal symptoms.
- Inform patient that quetiapine therapy may cause dizziness or drowsiness. Advise him not to drive or perform other activities that require alertness until drug's full CNS effects are known. Also, review fall precautions with patient.
- Instruct patient to rise slowly from a lying or seated position to reduce the risk of dizziness or fainting.
- Caution patient to avoid consuming alcoholic beverages because they can increase dizziness and drowsiness.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes and particularly if patient is a child or young adult.
- Encourage patient on long-term therapy to have regular eye examinations so that cataracts can be detected.
- Advise patient to contact prescriber if his pulse rate becomes abnormally slow or irregular.
- Alert patient that a false positive drug test for methadone or tricyclic antidepressants may occur with quetiapine use.

**quinapril hydrochloride**

# Accupril

## Class and Category

*Pharmacologic class:* Angiotensin converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive

## Indications and Dosages

➤ *To treat hypertension*

### **TABLETS**

**Adults not on diuretics.** *Initial:* 10 or 20 mg daily, adjusted every 2 wk based on clinical response.

*Maintenance:* 20 to 80 mg daily or in divided doses twice daily.

➤ *As adjunct to manage heart failure*

### **TABLETS**

**Adults.** *Initial:* 5 mg twice daily, increased, weekly as needed and tolerated. *Maintenance:* 20 to 40 mg twice daily given in two equally divided doses.

***DOSAGE ADJUSTMENT*** For patients who are dehydrated from previous diuretic therapy, those who are still receiving diuretic therapy, and those with creatinine clearance of 30 to 60 ml/min, initial dosage reduced to 5 mg daily. For patients with creatinine clearance of 10 to 30 ml/min, initial dosage reduced to 2.5 mg daily. For elderly patients, initial dosage reduced to 10 mg once daily, then titrated slowly to optimal response.

Route	Onset	Peak	Duration
P.O.	In 1 hr	2-4 hr	Up to 24 hr

## Mechanism of Action

Blocks conversion of angiotensin I to angiotensin II, leading to vasodilation, and reduces aldosterone secretion, which prevents water retention. Quinapril also reduces peripheral arterial resistance. These combined actions lead to a reduction in blood pressure. The reduction of aldosterone secretion also helps to relieve fluid buildup in heart failure.

## Contraindications

Aliskiren therapy in patients with diabetes history of angioedema related to previous treatment with ACE inhibitor, hypersensitivity to quinapril or its components, use of a neprilysin inhibitor such as sacubitril within 36 hours

## Interactions

### DRUGS

*aliskiren (patients with diabetes and/or renal impairment), angiotensin receptor blockers, other ACE inhibitors:*

Increased risk of hyperkalemia, hypotension, and renal dysfunction

*diuretics:* Increased risk of hypotension

*lithium:* Possibly increased blood lithium level and risk of toxicity

*mTOR inhibitors such as temsirolimus, neprilysin inhibitors such as sacubitril:* Increased risk of angioedema

*NSAIDs:* Decreased antihypertensive effect of quinapril; increased risk of renal dysfunction in the elderly or patients

who have preexisting renal dysfunction or are volume depleted

*potassium preparations, potassium-sparing diuretics,*

*potassium supplements:* Increased risk of hyperkalemia

*sodium aurothiomalate:* Possibly nitritoid reactions such as facial flushing, hypotension, nausea, vomiting

*tetracyclines:* Reduced tetracycline absorption

## **FOODS**

*foods high in potassium such as milk or potatoes,*

*potassium-containing, salt substitutes:* Increased risk of hyperkalemia

## **Adverse Reactions**

**CNS:** **CVA**, depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, light-headedness, malaise, nervousness, paresthesia, sleep disturbance, somnolence, syncope, vertigo

**CV:** Angina pectoris, **arrhythmias**, **cardiogenic shock**, chest pain, edema, **heart failure**, **hypertensive crisis**, **hypotension**, orthostatic hypotension, **MI**, palpitations, tachycardia, vasodilation

**EENT:** Amblyopia, dry mouth or throat, loss of taste, pharyngitis

**GI:** Abdominal pain, constipation, diarrhea, dyspepsia, elevated liver enzymes, flatulence, **GI hemorrhage**, **hepatitis**, indigestion, nausea, **pancreatitis**, vomiting

**GU:** **Acute renal failure**, elevated blood urea nitrogen and creatinine, impotence, UTI, **worsening renal failure**

**HEME:** **Agranulocytosis**, **hemolytic anemia**, **thrombocytopenia**

**MS:** Arthralgia, back pain, myalgia

**RESP:** Cough, dyspnea, **eosinophilic pneumonitis**

**SKIN:** Alopecia, dermatopolymyositis, diaphoresis, **exfoliative dermatitis**, flushing, pemphigus, photosensitivity, pruritus, rash, urticaria  
**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia**, **hyponatremia**

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm, especially if exposure occurs during the second or third trimester.
- Drug reduces fetal renal function leading to anuria and renal failure and increases fetal and neonatal morbidity and death. It can also cause fetal lung hypoplasia, hypotension, and skeletal deformations such as skull hypoplasia.
- Drug is contraindicated in pregnant women and should be discontinued as soon as possible if pregnancy occurs.

### LACTATION

- Drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use quinapril cautiously in patients with diabetes mellitus, renal impairment, or patients taking concomitant therapy with drugs that raise potassium levels. Monitor serum potassium levels, as ordered, in these patients and assess patient often for signs and symptoms of hyperkalemia.

**WARNING** Keep in mind patients with heart failure, hyponatremia, or severe salt or volume depletion; those who've recently received intensive diuresis or an increase in diuretic dosage; and those undergoing

dialysis may be at risk for excessive hypotension. Monitor blood pressure often for first 2 weeks of therapy and whenever quinapril or diuretic dosage increases. If excessive hypotension occurs, notify prescriber immediately, place patient in a supine position, and, if prescribed, infuse normal saline solution.

**WARNING** Know that because of the risk of angioedema, be prepared to discontinue drug and administer emergency measures, including subcutaneous epinephrine 1:1,000 (0.3 to 0.5 ml), if swelling of glottis, larynx, or tongue causes airway obstruction. Know that patients with a history of angioedema unrelated to ACE inhibitor therapy may be at increased risk of angioedema while receiving quinapril.

- Monitor patient's vital signs and cardiopulmonary status often to assess drug's effectiveness.

## **PATIENT TEACHING**

- Instruct patient to notify prescriber immediately and stop taking quinapril if he has difficulty breathing or swallowing or he experiences swelling of the eyes, face, lips, or tongue.
- Explain that drug may cause dizziness and light-headedness, especially for first few days of therapy. Advise patient to avoid hazardous activities until drug's CNS effects are known and to notify prescriber if he faints.
- Inform women of childbearing age of risks of taking quinapril during pregnancy. Caution her to use effective contraception and to notify prescriber immediately of known or suspected pregnancy.
- Advise patient having surgery or receiving anesthesia to tell specialist that he takes quinapril.
- Instruct patient to consult prescriber before using potassium supplements or salt substitutes that contain potassium.

# quinidine gluconate

## quinidine sulfate

### Class and Category

*Pharmacologic class:* Cinchona alkaloid

*Therapeutic class:* Class IA antiarrhythmic

### Indications and Dosages

- *To restore normal sinus rhythm in patients with symptomatic atrial fibrillation or atrial flutter*

#### **E.R. TABLETS (QUINIDINE GLUCONATE)**

**Adults.** 648 mg every 8 hr, increased cautiously after 3 to 4 doses, if needed. Alternatively, 324 mg every 8 hr for 2 days, increased to 648 mg every 12 hr for 2 days, and finally 648 mg every 8 hr for up to 4 days.

#### **E.R. TABLETS (QUINIDINE SULFATE)**

**Adults.** 300 every 8 to 12 hr with dosage cautiously increased if conversion not attained.

#### **TABLETS (QUINIDINE SULFATE)**

**Adults.** *Initial:* 400 mg every 6 hr with dosage cautiously increased if conversion not attained after 4 or 5 doses.

#### **I.V. INFUSION (QUINIDINE GLUCONATE)**

**Adults.** No faster than 0.25 mg/kg/min and discontinued when sinus rhythm has been restored.

- *To reduce frequency of relapse into atrial fibrillation or atrial flutter*

## **E.R. TABLETS (QUINIDINE GLUCONATE)**

**Adults.** 324 mg every 8 to 12 hr, then dosage cautiously increased if serum quinidine levels are within therapeutic range and average time between arrhythmic episodes has not been satisfactorily increased.

## **E.R. TABLETS (QUINIDINE SULFATE)**

**Adults.** 300 mg every 8 to 12 hr with dosage cautiously increased if serum quinidine levels are within therapeutic range and average time between arrhythmic episodes has not been satisfactorily increased.

## **tablets (quinidine sulfate)**

**Adults.** 200 mg every 6 hr with dosage cautiously increased if serum quinidine levels are within therapeutic range and average time between arrhythmic episodes has not been satisfactorily increased.

- *To treat life-threatening Plasmodium falciparum malaria*

## **I.V. INFUSION (QUINIDINE GLUCONATE)**

**Adults.** *Loading dose:* 24 mg/kg in 250 ml of normal saline infused over 4 hr. *Maintenance:* 12 mg/kg infused over 4 hr every 8 hr, starting 8 hrs after the beginning of the loading dose for 7 days unless patient able to swallow, then dosage switched to oral form. Alternatively, *Loading dose:* 10 mg/kg in 250 ml of normal saline infused over 1 to 2 hr. *Maintenance:* 0.02 mg/kg/min for 72 hr or until

parasitemia had decreased to 1% or less, whichever comes first.

Route	Onset	Peak	Duration
P.O.	Unknown	Unknown	6-8 hr
P.O. (E.R.)	Unknown	Unknown	12 hr
I.V.	Unknown	Unknown	Unknown

## Mechanism of Action

Depresses conduction velocity, contractility, and excitability of the myocardium and increases the effective refractory period, thus suppressing arrhythmic activity in the atria, ventricles, and His-Purkinje system. In malaria, quinidine acts primarily as an intraerythrocytic schizonticide.

## Contraindications

History of quinidine-or quinine-associated thrombocytopenic purpura; hypersensitivity to quinidine or its components; myasthenia gravis or other conditions that might be adversely affected by anticholinergic effects; presence of AV junctional or idioventricular pacemaker, including those in complete AV block

## Interactions

### DRUGS

*antacids*: Possibly delayed oral absorption of quinidine  
*antiarrhythmics, phenothiazines*: Additive cardiac effects  
*anticholinergics*: Possibly intensified atropine-like adverse effects

*anticonvulsants*: Possible accelerated clearance of quinidine reducing effectiveness

*antihypertensives*: Increased risk of hypotension

*cimetidine*: Increased elimination half-life, possibly leading to quinidine toxicity

*cholinergic agents*: Antagonized effects of cholinergic agents

*clarithromycin*: Possible but rarely torsades de pointes occurrence

*dextromethorphan*: Substantial increase in bioavailability of dextromethorphan

*digoxin*: Possibly digitalis toxicity

*diltiazem*: Decreased clearance and increased half-life of quinidine

*felodipine*: Possibly decreased metabolism of felodipine

*haloperidol*: Increased serum haloperidol concentrations

*ketoconazole*: Increased plasma quinidine levels

*nifedipine*: Decreased serum quinidine concentrations and decreased rate of nifedipine metabolism

*neuromuscular blockers*: Possibly potentiated neuromuscular blockade

*reserpine*: Possible additive cardiac depressant effects

*rifampin*: Possible accelerated quinidine elimination

*quinine*: Increased risk of quinidine toxicity

*verapamil*: Possibly decreased clearance of quinidine, additive effects, and hypotension in patients with an arrhythmia or hypertrophic cardiomyopathy

*warfarin*: Potentiates anticoagulant effect of warfarin

## **ACTIVITIES**

## **FOOD**

*grapefruit juice*: Possibly delay GI absorption of oral quinidine

# Adverse Reactions

**CNS:** Anxiety, asthenia, ataxia, confusion, delirium, difficulty speaking, dizziness, drowsiness, extrapyramidal reactions, fever, headache, hypertonia, syncope, vertigo

**CV:** **Complete heart block**, orthostatic hypotension, palpitations, peripheral edema, **prolonged QT interval**, **torsades de pointes**, vasculitis, **ventricular arrhythmias**, **widening QRS complex**

**EENT:** Blurred vision, change in color perception, diplopia, dry mouth, hearing loss (high-frequency), pharyngitis, photophobia, rhinitis, tinnitus

**GI:** Abdominal pain, anorexia, constipation, diarrhea, indigestion, nausea, vomiting

**HEME:** **Agranulocytosis**, **hemolytic anemia**, **leukopenia**, **neutropenia**, **thrombocytopenia**, **thrombocytopenic purpura**

**MS:** Arthralgia, myalgia

**RESP:** Dyspnea

**SKIN:** Diaphoresis, eczema, **exfoliative dermatitis**, flushing, hyperpigmentation, photosensitivity, pruritus, psoriasis, purpura, rash, urticaria

**Other:** **Angioedema**, flu-like symptoms, weight gain

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- Breastfeeding is not recommended during breastfeeding.

## Nursing Considerations

- For intermittent I.V. infusion, administer using an infusion pump at a rate of 0.25 mg/kg/min or less. Rapid administration may cause hypotension. Monitor blood pressure and ECG tracings throughout administration.
- Monitor therapeutic blood level of quinidine, as ordered.
- Monitor heart rate and rhythm closely because quinidine may cause serious adverse reactions and can be cardiotoxic, especially at dosages exceeding 2.4 g daily. Implement continuous cardiac monitoring, as ordered.
- Assess for early signs and symptoms of cinchonism, including blurred vision, change in color perception, confusion, diplopia, headache, and tinnitus, which may indicate quinidine toxicity.

## PATIENT TEACHING

- Advise patient to take quinidine at the same times every day and at evenly spaced intervals.
- Instruct patient to swallow E.R. tablets whole, with a full glass of water, preferably while sitting upright.
- Advise patient to take drug with food if GI upset occurs.
- Urge patient to inform prescriber immediately of blurred or double vision, change in color perception, confusion, diarrhea, fever, headache, loss of hearing, or tinnitus.

**rabeprazole sodium**

**AcipHex, AcipHex Sprinkle**

## Class and Category

*Pharmacologic class:* Proton pump inhibitor

*Therapeutic class:* Antiulcer

## Indications and Dosages

- *To provide short-term treatment of erosive esophagitis or ulcerative gastroesophageal reflux disease (GERD)*

### DELAYED-RELEASE TABLETS

**Adults.** 20 mg daily for 4 to 8 wk; course may be repeated if healing has not occurred at the end of 8 wk.

- *To treat symptomatic GERD*

### DELAYED-RELEASE TABLETS

**Adults and adolescents age 12 and over.** 20 mg daily for 4 wk. Course may be repeated if symptoms aren't completely resolved.

### DELAYED-RELEASE CAPSULES (ACIPHEX SPRINKLE)

**Children ages 1 to 11 weighing 15 kg (33 lb) or more.** 10 mg once daily 30 min before a meal for up to 12 wk.

**Children ages 1 to 11 weighing less than 15 kg (33 lb).** 5 mg once daily 30 min before a meal up to 12 wk. Increased to 10 mg once daily, as needed.

- *To provide maintenance treatment of erosive esophagitis or GERD*

### DELAYED-RELEASE TABLETS

**Adults.** 20 mg daily for no longer than 12 months.

- *To promote healing of duodenal ulcer*

## **DELAYED-RELEASE TABLETS**

**Adults.** 20 mg daily after breakfast for up to 4 wk. Course may be repeated if symptoms aren't completely resolved.

- *As adjunct to reduce the risk of duodenal ulcer recurrence by eradicating *Helicobacter pylori**

## **delayed-release tablets**

**Adults.** 20 mg twice daily with morning and evening meals in conjunction with amoxicillin 1,000 mg and clarithromycin 500 mg twice daily for 7 days.

- *To treat hypersecretory conditions, such as Zollinger-Ellison syndrome*

## **DELAYED-RELEASE TABLETS**

**Adults.** *Initial:* 60 mg daily; may be increased, if needed, to 100 mg daily or 60 mg twice daily.

## **Mechanism of Action**

Decreases gastric acid secretion by suppressing its release at the secretory surface of gastric parietal cells.

Rabeprazole also increases gastric pH and decreases basal acid output, which helps to heal ulcerated areas. In gastric parietal cells, it's transformed to an active sulfonamide, which increases the clearance rate of *H. pylori*.

## **Contraindications**

Concurrent therapy with rilpivirine-containing products; hypersensitivity to rabeprazole, other substituted

benzimidazoles (lansoprazole, omeprazole), or their components

## Interactions

### DRUGS

*atazanavir, nelfinavir, rilpivirine*: Decreased exposure of these antiretrovirals with possible decreased antiviral effect and increased development of drug resistance

*clarithromycin*: Increased risk of serious adverse reactions, including possibly fatal arrhythmias

*dasatinib, erlotinib, iron salts, itraconazole, ketoconazole, mycophenolate mofetil, nilotinib*: Reduced absorption of these drugs decreasing effectiveness

*digoxin*: Increased risk of digitalis toxicity

*methotrexate*: Increased risk of methotrexate toxicities

*saquinavir*: Increased exposure resulting in possible increased toxicity

*tacrolimus*: Possibly increased exposure of tacrolimus, especially in transplant patients who are intermediate or poor metabolizers of CYP2C19

*warfarin*: Possibly increased prothrombin time (PT), international normalized ratio (INR)

## Adverse Reactions

**CNS:** **Coma**, delirium, disorientation, dizziness, headache, malaise, vertigo

**EENT:** Blurred vision

**ENDO:** Elevated TSH levels

**GI:** Abdominal pain, ***Clostridium difficile*-associated diarrhea**, diarrhea, fundic gland polyps, jaundice, nausea, vomiting

**GU:** Interstitial nephritis

**HEME:** Agranulocytosis, hemolytic anemia, leukopenia, pancytopenia, thrombocytopenia

**MS:** Bone fracture, rhabdomyolysis

**RESP:** Bronchospasm, interstitial pneumonia

**SKIN:** Cutaneous lupus erythematosus, bullous and other drug skin eruptions, erythema multiforme, rash, Stevens-Johnson syndrome, toxic epidermal necrolysis, urticaria

**Other:** Anaphylaxis, angioedema, hyperammonemia, hypomagnesemia, systemic lupus erythematosus, vitamin B12 deficiency (long-term use)

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Use rabeprazole cautiously in patients with hepatic dysfunction.
- Obtain a serum magnesium level, as ordered, prior to starting rabeprazole therapy for those patients expected to be on prolonged therapy or who also take digoxin or drugs that may cause hypomagnesemia such as diuretics when taken with rabeprazole.
- Expect to monitor serum gastrin level in long-term therapy to detect elevation.

- Closely monitor Japanese men receiving rabeprazole for adverse reactions because they're more likely than other patients to have increased blood drug levels.
- Be aware that symptomatic response to rabeprazole therapy does not preclude the presence of a gastric tumor. Expect patients who have a suboptimal response or an early symptomatic relapse after completing rabeprazole therapy to have further diagnostic testing done.
- Monitor patient for bone fracture, especially in patient receiving multiple daily doses for more than a year because proton pump inhibitors like rabeprazole increase risk of osteoporosis-related fractures of the hip, wrist, and spine.
- Monitor patient for diarrhea because *diarrhea including C. difficile*-associated diarrhea may occur with rabeprazole therapy. Notify prescriber if persistent or severe diarrhea develops.
- Monitor patient's magnesium level, as ordered during therapy, because hypomagnesemia may occur with rabeprazole therapy that has lasted longer than 3 months, although most cases have occurred after therapy had been given for more than a year. Notify prescriber if magnesium level drops below normal, as hypomagnesemia may cause tetany, arrhythmias, and seizures. Expect patient to receive magnesium replacement and drug to be discontinued.
- Monitor patient for arthralgia and rash, as rabeprazole may cause either cutaneous or systemic lupus erythematosus in patients as a new onset or an exacerbation of the existing autoimmune disease. Know that proton pump inhibitors like rabeprazole should not be given longer than necessary. If patient becomes symptomatic, notify prescriber. If confirmed, expect drug to be discontinued. Know that most patients improve within 12 weeks after drug is discontinued.
- Be aware that rabeprazole may produce false readings on the following tests: secretin stimulation test assessing for gastrinoma and serum chromogranin levels assessing for neuroendocrine tumors; these require rabeprazole to be withheld for at least 14 days before tests are performed. Urine tests for tetrahydrocannabinol may result in a false-positive result.

## **PATIENT TEACHING**

- Tell patient to take rabeprazole 30 minutes before a meal.
- Instruct patient to swallow delayed-release rabeprazole tablets whole and not to chew, crush, or split tablets.

- Instruct parents whose child is prescribed delayed-release capsules to make sure that child swallows capsule whole and does not chew or crush granules. If patient is unable to swallow capsule, tell parents that delayed-release capsules may be opened and contents may be sprinkled on a small amount of soft food such, as applesauce or yogurt. Contents may also be emptied into a small amount of liquid, such as apple juice, infant formula, or pediatric electrolyte solution. The dose should be taken within 15 minutes of preparation. Remind parents that food or liquid used to mix granules in should be at or below room temperature. Unused mixture should be discarded.
- Instruct patient to notify prescriber immediately if he develops new or worsening joint pain or a rash on his arms or cheeks that gets worse in the sun.
- Inform patients with hypersecretory conditions, such as Zollinger-Ellison syndrome, that treatment can last for a year or longer.
- Tell patient to notify prescriber immediately if he experiences a decrease in the amount of urine voided or if urine has blood in it.
- Advise patient to contact prescriber if he develops persistent or severe diarrhea that is accompanied by abdominal pain and fever.
- Instruct patient to notify prescriber of any persistent, severe, or unusual adverse reactions.
- Tell patient to inform all prescribers of rabeprazole therapy.
- Inform patient that vitamin B12 deficiency may occur if drug is taken longer than 3 years.

## raloxifene hydrochloride

**Evista**

### **Class and Category**

*Pharmacologic class:* Selective estrogen receptor modulator (ISERM)

*Therapeutic class:* Antiosteoporotic

## Indications and Dosages

- *To prevent osteoporosis in postmenopausal women; to reduce risk of invasive breast cancer in postmenopausal women with osteoporosis; to reduce risk of invasive breast cancer in postmenopausal women at high risk*

### **TABLETS**

**Adults.** 60 mg daily.

## Mechanism of Action

Prevents osteoporosis by binding to estrogen receptors, which decreases bone resorption and increases bone mineral density in postmenopausal women. May reduce risk of invasive breast cancer because of its binding effects on estrogen receptors.

## Contraindications

Active or past history of thromboembolic disease, hypersensitivity to raloxifene or its components, pregnancy

## Interactions

### **DRUGS**

*cholestyramine:* Decreased raloxifene absorption  
*diazepam, diazoxide, lidocaine, other highly protein-bound drugs:* Possibly interference with binding sites  
*systemic estrogens:* Safety not known  
*warfarin:* Possibly decreased PT

# Adverse Reactions

**CNS:** CVA, depression, fever, insomnia, migraine

**CV:** Chest pain, hot flashes, peripheral edema, thromboembolism, thrombophlebitis

**EENT:** Laryngitis, pharyngitis, sinusitis

**ENDO:** Hot flashes

**GI:** Abdominal pain, cholelithiasis, flatulence, indigestion, nausea, vomiting

**GU:** Cystitis, infertility, leukorrhea, UTI, vaginitis

**MS:** Arthralgia, arthritis, leg cramps or spasms, myalgia

**RESP:** Cough, pneumonia, pulmonary embolism

**SKIN:** Diaphoresis, rash

**Other:** Flu-like symptoms, weight gain

# Childbearing Considerations

## PREGNANCY

- Drug is not for use in females of childbearing age.
- Drug is contraindicated in pregnant women.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is not for use in females of childbearing age.

# Nursing Considerations

- Be aware that raloxifene should not be used in premenopausal women.
- Use cautiously in patients who smoke or have a history of atrial fibrillation, hypertension stroke, or TIA because raloxifene may increase the risk of stroke.

- Use cautiously in patients with renal impairment because effects of raloxifene on renal system are unknown.

**WARNING** Monitor patient's limbs for impaired circulation and pain (possible thromboembolism).

- Expect prescriber to stop drug at least 72 hours before and during periods of prolonged immobilization. Resume raloxifene therapy as prescribed after patient is fully ambulatory.

## PATIENT TEACHING

- Advise patient to avoid lengthy immobility during travel while taking raloxifene because of the increased risk of thromboembolism.
- Instruct patient to report adverse reactions to prescriber immediately, especially coughing up blood, leg pain or swelling, shortness of breath, a sudden change in vision, or sudden chest pain.
- Emphasize the importance of compliance with long-term raloxifene therapy.
- Advise patient that postmenopausal women require an average of 1,500 mg of elemental calcium and 400 to 800 international units of vitamin D daily. Vitamin D requirement is increased in women who are chronically ill or nursing-home bound, women with GI malabsorption syndromes, and women over age 70. Review dietary sources of calcium and vitamin D, and have patient discuss supplements with prescriber, as needed.

## raltegravir potassium

**Isentress, Isentress HD**

## Class and Category

*Pharmacologic class:* HIV integrase strand transfer inhibitor

*Therapeutic class:* Antiretroviral

# Indications and Dosages

- *As adjunct to treat human immunodeficiency virus (HIV-1) infection*

## CHEWABLE TABLETS, TABLETS

**Adults who are treatment-naïve or who are virologically suppressed on an initial regimen of raltegravir of 400 mg twice daily.** 1,200 mg once daily if using 600-mg film-coated tablets or 400 mg twice daily if using 400-mg film-coated tablets.

**Adults who are treatment-experienced.** 400 mg twice daily using 400-mg film-coated tablets.

**Adults who are treatment-experienced or treatment-naïve and taking rifampin concomitantly.** 800 mg twice daily using 400-mg film-coated tablets.

**Children weighing at least 40 kg (88 lb) and are treatment-naïve or virologically suppressed on an initial regimen of raltegravir 400 mg twice daily.** 1,200 mg once daily using 600-mg film-coated tablets, 400 mg twice daily using 400-mg film-coated tablets, or 300 mg twice daily using chewable tablets.

## CHEWABLE TABLETS, TABLETS

**Children who weigh at least 28 kg (61.6 lb) but less than 40 kg (88 lb).** 400 mg twice daily using 400-mg film-coated tablets or 200 mg twice daily using chewable tablets.

**Children who weigh at least 25 kg (55 lb) but less than 28 kg (61.6 lb).** 400 mg twice daily using 400-mg film-coated tablets or 150 mg twice daily using chewable tablets.

## CHEWABLE TABLETS

**Children who weigh 20 kg (44 lb) to less than 25 kg (55 lb) and are 4 weeks of age and over.** 150 mg twice daily.

## **CHEWABLE TABLETS, ORAL SUSPENSION**

**Children who weigh 14 kg (30.8 lb) to less than 20 kg (44 lb) and are 4 weeks of age and over.** 100 mg twice daily.

**Children who weigh 11 kg (24.2 lb) to less than 20 kg (44 lb) and are 4 weeks of age and over.** 75 mg twice daily using chewable tablets or 80 mg twice daily using oral suspension.

## **ORAL SUSPENSION**

**Children who are at least 4 weeks old and weigh 14 kg (31 lb) to less than 20 kg (44 lb).** 100 mg twice daily.

**Children who are at least 4 weeks old and weigh 11 kg (24.2 lb) to less than 14 kg (31 lb).** 80 mg twice daily.

**Children at least 4 weeks of age and who weigh 8 kg (17.6 lb) to less than 11 kg (24.2 lb) and are 4 weeks of age and over.** 60 mg twice daily.

**Children who are at least 4 weeks of age and who weigh 6 kg (13.2 lb) to less than 8 kg (17.6 lb) and are 4 weeks of age and over.** 40 mg twice daily.

**Children who are at least 4 weeks of age and who weigh 4 kg (8.8 lb) to less than 6 kg (13.2 lb) and are 4 weeks of age and over.** 30 mg twice daily.

**Children who are at least 4 weeks of age and who weigh 3 kg (6.6 lb) to less than 4 kg (8.8 lb) and are 4 weeks of age and over.** 25 mg twice daily.

**Neonates age 1 to 4 weeks weighing 4 kg (8.8 lb) to less than 5 kg (11 lb).** 15 mg twice daily.

**Neonates age 1 to 4 weeks weighing 3 kg (6.6 lb) to less than 4 kg (8.8 kg).** 10 mg twice daily.

**Neonates age 1 to 4 weeks weighing 2 kg (4.4 lb) to less than 3 kg (6.6 lb).** 8 mg twice daily.

**Neonates age birth to 1 week weighing 4 kg (8.8 lb) to less than 5 kg (11 lb).** 7 mg once daily.

**Neonates age birth to 1 week weighing 3 kg (6.6 lb) to less than 4 kg (8.8 lb).** 5 mg once daily.

**Neonates age birth to 1 week weighing 2 kg (4.4 lb) to less than 3 kg (6.6 lb).** 4 mg once daily.

Note: If the mother has taken raltegravir 2 to 24 hours before delivery, then the neonate, age birth to 4 weeks, should be given the first dose, regardless of weight, between 24 and 48 hr after birth.

## **Mechanism of Action**

Inhibits HIV integrase by binding to the integrase active site and blocking the strand transfer step of retroviral DNA integration, which is needed for the HIV replication cycle.

## **Contraindications**

Hypersensitivity to raltegravir or its components

## **Interactions**

### **DRUGS**

*aluminum- and/or magnesium-containing antacids, calcium carbonate antacid, carbamazepine, etravirine, phenobarbital, phenytoin, rifampin:* Decrease in plasma concentration of raltegravir and its effectiveness

# Adverse Reactions

**CNS:** Abnormal dreams, asthenia, cerebellar ataxia, depression, dizziness, fatigue, fever, headaches, insomnia, malaise, nightmares, paranoia, **suicidal ideation**

**CV:** Elevated cholesterol and triglycerides

**EENT:** Conjunctivitis

**ENDO:** Hyperglycemia

**GI:** Abdominal pain, anorexia, bilirubin increase, diarrhea, dyspepsia, elevated liver and pancreatic enzymes, flatulence, gastritis, **hepatic failure**, **hepatitis**, nausea, vomiting

**GU:** Genital herpes, nephrolithiasis, **renal failure**

**HEME:** Decreased hemoglobin count, **neutropenia**, **thrombocytopenia**

**MS:** Elevated creatine kinase, myopathy, **rhabdomyolysis**

**SKIN:** Blisters, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**

**Other:** **Angioedema**, herpes zoster, **hypersensitivity reactions**, immune reconstitution syndrome

# Childbearing Considerations

## PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.

- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Ask patient before starting raltegravir therapy if he has ever experienced an elevated creatine kinase level, myopathy, or rhabdomyolysis or is taking any drugs known to cause these conditions (such as fenofibrate, gemfibrozil, statins, or zidovudine), because drug may increase risk of developing these conditions.
- Know that chewable tablets and oral suspension cannot be substituted for the 400-mg or 800-mg film-coated tablets, because the formulations have different pharmacokinetic profiles.
- Be aware that raltegravir should not be given before dialysis, because the extent to which the drug is dialyzable is unknown.
- Mix oral suspension form by pouring packet contents into 5 ml of water and mixing. Once mixed, measure the recommended dose with a syringe and administer within 30 minutes of mixing. Discard any remaining suspension.

**WARNING** Monitor patient closely for severe skin reactions.

Notify prescriber and expect raltegravir to be discontinued immediately if patient develops a rash that is accompanied by angioedema, blisters, conjunctivitis, eosinophilia, facial edema, fatigue, fever, joint or muscle aches, lip swelling, malaise, or oral lesions. Be aware that a delay in discontinuing drug may result in a life-threatening situation.

- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including raltegravir. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Advise patient to avoid missing doses of raltegravir, as it can result in the development of resistance to the drug. If he misses a dose, he should take it as soon as he remembers, but should not double the next dose or take more than prescribed.
- Instruct patient to swallow film-coated tablets whole; chewable tablets may be swallowed whole or chewed.
- Tell patient or parents, if patient is prescribed oral suspension form, to pour packet into 5 ml of water and mix. Dosage of drug should be measured with a syringe and administered within 30 minutes of mixing. Any leftover suspension should be discarded.
- Alert patient or parents that chewable tablet form contains phenylalanine and can be harmful to patients with phenylketonuria.

**WARNING** Inform patient to seek immediate medical attention if a rash develops or other signs and symptoms that are new, persistent, or severe appear, including evidence of an infection.

- Advise female patient to alert prescriber if pregnancy is suspected or has occurred and encourage her to register with the Antiretroviral Pregnancy Registry by calling 1-800-258-4263.
- Inform mothers that breastfeeding is not recommended during raltegravir therapy.
- Instruct patient to immediately report any unexplained muscle pain, tenderness, or weakness.

**ramelteon**

**Rozerem**

## Class and Category

*Pharmacologic class:* Melatonin receptor agonist

*Therapeutic class:* Hypnotic

## Indications and Dosages

- *To treat insomnia in patients having difficulty falling asleep*

### **TABLETS**

**Adults.** 8 mg 30 min before at bedtime.

Route	Onset	Peak	Duration
P.O.	Unknown	0.5–1.5 hr	Unknown

## Mechanism of Action

Binds to melatonin receptors MT1 and MT2 in the suprachiasmatic nucleus (SCN) of the hypothalamus. The SCN regulates the sleep–wake cycle, and endogenous melatonin probably is involved in maintaining the circadian rhythm underlying that cycle.

## Contraindications

Concurrent therapy with fluvoxamine, history of angioedema with previous ramelteon treatment, hypersensitivity to ramelteon or its components

## Interactions

### **DRUGS**

*benzodiazepines, melatonin, other sedative-hypnotics:*  
Possible additive sedative effects

*donepezil, doxepin, fluconazole, fluvoxamine, ketoconazole:*  
Increased plasma ramelteon levels  
*rifampin:* Decreased ramelteon effectiveness

## ACTIVITIES

*alcohol use:* Possibly additive CNS effect

## Adverse Reactions

**CNS:** Agitation, amnesia, anxiety, bizarre behavior, complex behaviors such as sleep driving, depression, dizziness, fatigue, hallucinations, headache, insomnia exacerbation, mania, somnolence, **suicidal ideation**

**EENT:** **Throat tightness**

**ENDO:** Decreased testosterone level, increased prolactin level

**GI:** Diarrhea, dysgeusia, nausea, vomiting

**MS:** Arthralgia, myalgia

**RESP:** Dyspnea, upper respiratory tract infection

**Other:** **Anaphylaxis, angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

- If breastfeeding occurs, advise mother to monitor breastfed infant for feeding difficulties and somnolence.

## Nursing Considerations

- Be aware that ramelteon therapy is not recommended for patients with COPD or severe sleep apnea because its effects have not been studied in these patient populations.
- Use cautiously in patients with mild-to-moderate hepatic dysfunction. Drug is contraindicated in severe hepatic dysfunction.
- Ramelteon is the first approved hypnotic not classified as a controlled substance.

**WARNING** Monitor patient closely for hypersensitivity reactions such as dyspnea, nausea, swelling, throat tightness, and vomiting. If present, discontinue ramelteon immediately, notify prescriber, and provide supportive care.

- Watch patient closely for suicidal tendencies, particularly when therapy starts and dosage changes, because depression may worsen temporarily during these times, possibly leading to suicidal ideation.

## PATIENT TEACHING

- Instruct patient not to take ramelteon with or immediately after eating a high-fat meal.
- Caution patient to avoid potentially hazardous activities after taking ramelteon; drug's intended effect is to decrease alertness.
- Advise patient that drug may cause abnormal behaviors during sleep, such as driving a car, eating, having sex, or talking on the phone without any recall of the event. If family members notice any such behavior or patient sees evidence of such behavior upon awakening, prescriber should be notified.
- Advise limiting alcohol during therapy.

- Tell patient to notify prescriber if insomnia worsens or new signs or symptoms occur.
- Inform patient that drug may affect reproductive hormones; urge patient to report cessation of menses or galactorrhea (females) or decreased libido or problems with infertility.
- Advise mothers who are breastfeeding while taking ramelteon to monitor infant for signs of feeding problems and sedation. Tell her to consider pumping and discarding breast milk during treatment and for 25 hours after ramelteon administration, to minimize drug exposure of her infant.
- Urge family or caregiver to watch patient closely for suicidal tendencies, especially when therapy starts or dosage changes.

**ramipril**

**Altace**

## Class and Category

*Pharmacologic class:* Angiotensin converting enzyme (ACE) inhibitor

*Therapeutic class:* Antihypertensive

## Indications and Dosages

➤ *To treat heart failure after MI*

### CAPSULES

**Adults.** *Initial:* 2.5 mg twice daily with dose decreased to 1.25 mg twice daily if hypotension occurs. Dosage increased, as needed, about every 3 wk to maintenance dose. *Maintenance:* 5 mg twice daily.

- *To reduce risk of MI or stroke and death from cardiovascular causes*

## CAPSULES

**Adults age 55 and over.** *Initial:* 2.5 mg once daily for 1 wk, followed by 5 mg once daily for 3 wk, and then increased, as tolerated to 10 mg once daily.

- *To treat hypertension*

## CAPSULES

**Adults not taking a diuretic.** *Initial:* 2.5 mg daily. *Maintenance:* 2.5 to 20 mg once daily or in divided doses twice daily.

**DOSAGE ADJUSTMENT** For patients dehydrated from diuretics, those receiving diuretics, and those with creatinine clearance less than 40 ml/min; initial dosage reduced to 1.25 mg daily and then slowly increased until blood pressure is under control or maximum daily dose of 5 mg is reached. For patients with heart failure post myocardial infarction, who cannot tolerate the initial dosage of 2.5 mg, once daily dosage reduced to 1.25 mg daily. For patients who are hypertensive or had recent post myocardial infarction, daily dose may be given in divided doses to reduce risk of MI, stroke, or death from cardiovascular causes.

Route	Onset	Peak	Duration
P.O.	1-2 hr	4-6.5 hr	24 hr

## Mechanism of Action

Blocks conversion of angiotensin I to angiotensin II, causing vasodilation, and reduces aldosterone secretion,

which prevents water retention. Ramipril also reduces peripheral arterial resistance. Combined, these actions reduce blood pressure.

## Contraindications

Aliskiren therapy in patients with diabetes; hypersensitivity to ramipril, other ACE inhibitors or their components; use of neprilysin inhibitor such as sacubitril within 36 hours

## Interactions

### DRUGS

*aliskiren (patients with diabetes and/or renal impairment), angiotensin receptor blockers, other ACE inhibitors:*

Increased risk of hyperkalemia, hypotension, and renal dysfunction

*diuretics:* Possibly hypotension

*lithium:* Increased risk of lithium toxicity

*mTOR inhibitors such as temsirolimus, neprilysin inhibitor such as sacubitril:* Increased risk of angioedema

*NSAIDs:* Decreased antihypertensive effect of ramipril; increased risk of renal dysfunction in the elderly and patients with preexisting renal dysfunction or volume depletion

*potassium preparations, potassium-sparing diuretics:* Risk of hyperkalemia

*sodium aurothiomalate:* Increased risk of nitritoid reaction (facial flushing, hypotension, nausea, vomiting)

### FOODS

*potassium-rich foods such as milk and potatoes, potassium-containing salt substitutes:* Increased risk of hyperkalemia

# Adverse Reactions

**CNS:** Depression, dizziness, drowsiness, fatigue, fever, headache, insomnia, light-headedness, malaise, paresthesia, sleep disturbance, syncope, vertigo

**CV:** Chest pain, **hypotension**, orthostatic hypotension, palpitations, tachycardia

**EENT:** Amblyopia, dry mouth, loss of taste, pharyngitis

**GI:** Abdominal pain, constipation, diarrhea, elevated liver enzymes, jaundice, **hepatic failure**, **hepatitis**, nausea, vomiting

**GU:** **Acute renal failure**, elevated BUN and serum creatinine levels, impotence, oliguria, **progressive azotemia**

**HEME:** **Agranulocytosis**, anemia, **bone marrow depression**, **pancytopenia**

**MS:** Arthralgia, back pain, myalgia

**RESP:** Cough, dyspnea

**SKIN:** Alopecia, diaphoresis, flushing, onycholysis, pemphigoid, photosensitivity, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, **hyperkalemia**

## Childbearing Considerations

### PREGNANCY

- Drug can cause fetal harm, especially if exposure occurs during the second or third trimester.
- Drug reduces fetal renal function leading to anuria and renal failure and increases fetal and neonatal morbidity and death. It can also cause fetal lung hypoplasia, hypotension, and skeletal deformations such as skull hypoplasia.

- Drug is contraindicated in pregnant women and should be discontinued as soon as possible if pregnancy occurs.

## LACTATION

- It is not known if drug is present in breast milk.
- Drug is not recommended for use during breastfeeding.

## Nursing Considerations

- Use ramipril cautiously in patients with renal or hepatic impairment.
- Monitor patient's serum potassium level, as ordered, and assess often for signs and symptoms of hyperkalemia, especially in patients with diabetes mellitus or renal insufficiency and those taking concomitantly other drugs that raise serum potassium levels.

**WARNING** Keep in mind patients with dehydration, heart failure, or hyponatremia; those who've recently received intensive diuresis or an increase in diuretic dosage; and those having dialysis may risk excessive hypotension. Monitor such patients closely the first 2 weeks of therapy and whenever ramipril or diuretic dosage increases. If excessive hypotension occurs, notify prescriber immediately, place patient in a supine position, and, if prescribed, infuse normal saline solution.

**WARNING** Know that because of the risk of angioedema, be prepared to stop drug and provide emergency measures, including subcutaneous epinephrine 1:1,000 (0.3 to 0.5 ml), if swelling of glottis, larynx, or tongue causes airway obstruction.

- Monitor blood pressure frequently during therapy to assess drug's effectiveness.

- Monitor patient's hepatic and renal function closely during therapy. If patient develops jaundice or marked elevations of hepatic enzymes, notify prescriber and expect ramipril to be discontinued.

## PATIENT TEACHING

- Advise patient to stop taking ramipril and inform prescriber immediately if she experiences difficulty breathing or swallowing or develops swelling of the eyes, face, lips, or tongue.
- Explain that drug may cause dizziness and light-headedness, especially during first few days of therapy. Instruct patient to notify prescriber immediately if she has fainting episode.
- Inform female patient of childbearing age of the risks of taking ramipril during pregnancy and to report known or suspected pregnancy immediately.
- Urge patient to tell providers that she takes ramipril before having surgery or receiving anesthesia.
- Tell patient to ask prescriber before using supplements or salt substitutes that contain potassium.

**ranolazine**

**Ranexa**

## Class and Category

*Pharmacologic class:* Cardiac agent

*Therapeutic class:* Antianginal

## Indications and Dosages

➤ *To treat chronic angina*

## E.R. TABLETS

**Adults.** *Initial:* 500 mg twice daily, increased to 1,000 mg twice daily, as needed. *Maximum:* 1,000 mg twice daily.

***DOSAGE ADJUSTMENT*** For patients taking a moderate CYP3A inhibitor, such as diltiazem, erythromycin, or verapamil, maximum dosage reduced to 500 mg twice daily. For patients taking P-gp inhibitors, such as cyclosporine, dosage may need to be reduced.

Route	Onset	Peak	Duration
P.O.	Unknown	2-5 hr	Unknown

## Mechanism of Action

Exerts antianginal and anti-ischemic effects by an unknown mechanism not dependent on reductions in blood pressure or heart rate. Ranolazine inhibits cardiac late sodium current, but how this action inhibits angina symptoms is also unknown.

## Contraindications

Hypersensitivity to ranolazine or its components, liver cirrhosis, use of CYP3A inducers or strong inhibitors

## Interactions

### DRUGS

*CYP2D6 substrates such as antipsychotics, tricyclic antidepressants:* Increased plasma levels of these drugs  
*CYP3A inducers, such as carbamazepine, phenobarbital, phenytoin, rifabutin, rifampin, rifapentine, St. John's wort:*

Decreased blood ranolazine level and decreased effectiveness

*CYP3A substrates, such as cyclosporine, lovastatin, simvastatin, sirolimus, tacrolimus:* Possibly increased blood levels of these drugs

*CYP3A inhibitors, such as clarithromycin, diltiazem, erythromycin, fluconazole, indinavir, itraconazole, ketoconazole, nefazodone, nelfinavir, ritonavir, saquinavir, verapamil:* Increased blood ranolazine level and increased risk of adverse reactions

*digoxin:* Increased blood digoxin level

*metformin:* Increased metformin levels when ranolazine dosage reaches 1,000 mg twice daily

## ACTIVITIES

*grapefruit juice, grapefruit containing products:* Increased blood ranolazine level and increased risk of adverse reactions

## Adverse Reactions

**CNS:** Abnormal coordination, asthenia, confusion, dizziness, hallucination, headache, hypoesthesia, myoclonus, paresthesia, syncope, tremor, vertigo

**CV:** **Bradycardia**, **hypotension**, orthostatic hypotension, palpitations, peripheral edema, **QT-interval prolongation**

**EENT:** Blurred vision, dry mouth, tinnitus

**ENDO:** **Hypoglycemia**

**GI:** Abdominal pain, anorexia, constipation, dyspepsia, nausea, vomiting

**GU:** Dysuria, elevated blood urea and creatinine levels, hematuria, **renal failure**, urinary retention

**HEME:** Eosinophilia, **leukopenia**, **pancytopenia**, **thrombocytopenia**

**RESP:** Dyspnea, **pulmonary fibrosis**

**SKIN:** Diaphoresis, pruritus, rash

**Other:** **Angioedema**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Monitor patient's QT interval, as ordered, because ranolazine prolongs it in a dose-related manner.
- Assess effectiveness of ranolazine at preventing anginal pain.
- Know that acute renal failure may occur in some patients with severe renal impairment (creatinine clearance less than 30 ml/min) while taking drug. Monitor patient's serum creatinine levels and blood urea nitrogen after drug therapy begins and then periodically, as ordered. If elevations occur, notify prescriber and expect drug to be discontinued.
- Monitor patient's serum magnesium, potassium, and liver enzyme levels.

### PATIENT TEACHING

- Instruct patient to take ranolazine exactly as prescribed.
- Inform patient that drug may be taken with or without food.

- Caution patient to swallow tablets whole and not to break, chew, or crush them.
- Advise patient to limit the amount of grapefruit and grapefruit juice consumed while taking this drug.
- Advise patient to notify prescriber if persistent or severe adverse reactions occur.
- Instruct patient to notify all prescribers of ranolazine use.

# rasagiline

## Azilect

## Class and Category

*Pharmacologic class:* Irreversible monoamine oxidase inhibitor (MAOI)

*Therapeutic class:* Antiparkinsonian

## Indications and Dosages

- *To treat idiopathic Parkinson's disease as initial monotherapy in early-stage disease; adjunct in patients not taking levodopa*

### **TABLETS**

**Adults.** 1 mg once daily.

- *As adjunct with levodopa in treatment of later-stage idiopathic Parkinson's disease*

### **TABLETS**

**Adults.** 0.5 mg once daily increased to 1 mg once daily, as needed.

**DOSAGE ADJUSTMENT** For patients with mild hepatic failure or taking ciprofloxacin or other CYP1A2 inhibitors, dosage shouldn't exceed 0.5 mg daily.

Route	Onset	Peak	Duration
P.O.	Unknown	1 hr	Unknown

## Mechanism of Action

Inhibits metabolic degradation of catecholamines and serotonin in the CNS and peripheral tissues, increasing extracellular dopamine level in the striatum. The increased dopamine level helps control alterations in voluntary muscle movement (such as rigidity and tremors) in Parkinson's disease because dopamine, a neurotransmitter, is essential for normal motor function. By stimulating central and peripheral dopaminergic 2 (D<sub>2</sub>) receptors on postsynaptic cells, dopamine inhibits firing of striatal neurons (such as cholinergic neurons), improving motor function.

## Contraindications

Concurrent therapy with cyclobenzaprine, dextromethorphan, or St. John's wort; hypersensitivity to rasagiline or its components; use within 14 days of MAO inhibitors, meperidine, methadone, other selective MAO-B inhibitors, propoxyphene, or tramadol

## Interactions

### DRUGS

*antipsychotics, metoclopramide*: Possible diminished effectiveness of rasagiline  
*CYP1A2 inhibitors such as ciprofloxacin*: Increased plasma rasagiline concentrations  
*dextromethorphan*: Increased risk of bizarre behavior or episodes of psychosis  
*meperidone, MAO inhibitors, selective MAO-B inhibitors*: Increased risk of serious, sometimes fatal, adverse reactions  
*MAO inhibitors, sympathomimetics*: Increased risk of hypertensive crisis  
*selective serotonin reuptake inhibitors*: serotonin norepinephrine reuptake inhibitors; tetracyclic, triazolopyridine, or tricyclic antidepressants: Increased risk of serotonin syndrome

## Activities

### FOOD

*foods high in tyramine*: Possibly significant increase in blood pressure

## Adverse Reactions

**CNS**: Abnormal dreams, amnesia, anxiety, asthenia, ataxia, **cerebral ischemia**, **coma**, compulsive behaviors (binge eating, increased sexual urges, intense urges to spend money), confusion, **CVA**, daytime sleepiness, depression, difficulty thinking, dizziness, dyskinesia, dystonia, fever, hallucinations, headache, malaise, manic depressive reaction, nightmares, paresthesia, psychotic-like behavior, **seizures**, **serotonin syndrome**, somnolence, stupor, syncope, vertigo

**CV:** Angina, bundle branch heart block, chest pain, **heart failure**, **MI**, **hypertensive crisis**, postural hypotension, thrombophlebitis, **ventricular fibrillation or tachycardia**

**EENT:** Blurred vision, conjunctivitis, dry mouth, epistaxis, gingivitis, **hemorrhage**, **laryngeal edema**, retinal detachment or hemorrhage, rhinitis

**GI:** Abdominal pain, anorexia, constipation, diarrhea, dyspepsia, dysphagia, elevated liver enzymes, gastroenteritis, **GI hemorrhage**, **intestinal obstruction or perforation**, nausea, vomiting

**GU:** **Acute renal failure**, albuminuria, decreased libido, hematuria, impotence, incontinence, priapism

**HEME:** Anemia, **leukopenia**, **thrombocytopenia**

**MS:** Arthralgia, arthritis, bone necrosis, bursitis, leg cramps, myasthenia, neck pain or stiffness, tenosynovitis

**RESP:** **Apnea**, **asthma**, cough, dyspnea, pleural effusion, **pneumothorax**, **interstitial pneumonia**

**SKIN:** Alopecia, **carcinoma**, diaphoresis, ecchymosis, **exfoliative dermatitis**, pruritus, ulcer, vesiculobullous rash

**Other:** **Angioedema**, flu-like symptoms, **hypersensitivity reactions**, **hypocalcemia**, weight loss

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.

- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

**WARNING** Monitor patient's blood pressure closely throughout therapy. Notify prescriber immediately if patient has evidence of hypertensive crisis or signs and symptoms suggesting a stroke. Expect to stop drug immediately if these occur.

- Keep phentolamine readily available to treat hypertensive crisis. Give 5 mg by slow I.V. infusion, as prescribed, to reduce blood pressure without causing excessive hypotension. Use external cooling measures, as prescribed, to manage fever.
- Monitor patient receiving rasagiline with levodopa for worsening of preexisting dyskinesia. If it occurs, notify prescriber and expect levodopa dosage to be decreased.
- Be aware that patient may experience orthostatic hypotension, especially in the first 2 months of rasagiline therapy and that it may also occur while patient is supine.

## PATIENT TEACHING

**WARNING** Inform patient taking recommended dosage of rasagiline that dietary tyramine restriction is no longer needed except for avoidance of very tyramine-rich foods such as aged cheese (e.g., Stilton), which may increase blood pressure greatly. If patient doesn't feel well soon after eating a suspected high-tyramine meal, he should contact prescriber immediately.

- Remind patient not to exceed the recommended dose because of risk of hypertension.
- Advise patient to stop taking rasagiline and to notify prescriber immediately if he develops blurred vision, chest pain, coma, nausea, palpitations, seizures, severe headache, stiff neck, stupor, trouble thinking, vomiting, or evidence of stroke.

**WARNING** Monitor patient closely for serotonin syndrome, a rare but serious adverse effect of rasagiline. Signs and symptoms include agitation, confusion, diaphoresis, diarrhea, fever, hyperactive reflexes, poor coordination, restlessness, shaking, talking or acting with uncontrolled excitement, tremor, and twitching. If symptoms occur, notify prescriber immediately, expect to discontinue drug, and provide supportive care.

- Suggest that patient change position slowly to minimize orthostatic hypotension.
- Alert patient that drug may cause changes in behavior that may be severe or hallucinations, especially at the initiation of drug therapy or when an increase in dosage occurs. If they occur, tell patient to notify prescriber promptly.
- Alert patient and caregivers that drug may cause compulsive or impulsive behaviors such as binge eating, gambling, increased sexual activities, or spending money inappropriately. If any questionable behavior occurs, instruct patient or caregiver to notify prescriber, as dosage may need to be adjusted or drug discontinued.
- Instruct patient to notify all prescribers of rasagiline therapy, especially if antidepressants or antibiotics such as ciprofloxacin or a similar drug are being considered, and to avoid taking any over-the-counter cold medications.
- Caution patient not to perform hazardous activities until CNS effects of drug are known. Some patients have fallen asleep without warning while engaged in activities of daily living, including driving.
- Instruct patient to notify prescriber if pregnancy occurs.

**repaglinide**

**Prandin**

## Class and Category

*Pharmacologic class:* Meglitinide

*Therapeutic class:* Antidiabetic

## Indications and Dosages

- *As adjunct to achieve glucose control in type 2 diabetes mellitus as monotherapy in patients whose glycosylated hemoglobin (HbA<sub>1c</sub>) level is less than 8%*

### **TABLETS**

**Adults.** *Initial:* 0.5 mg within 30 min before each meal. Dosage doubled, as needed, every wk until adequate glucose response obtained. *Maintenance:* 0.5 to 4 mg/dose up to four times a day. *Maximum:* 16 mg daily in divided doses of not more than 4 mg/dose.

- *As adjunct to achieve glucose control in type 2 diabetes mellitus as monotherapy in patients whose HbA<sub>1c</sub> is 8% or greater*

### **TABLETS**

**Adults.** *Initial:* 1 or 2 mg within 30 min before each meal. Dosage doubled, as needed, every wk until adequate glucose response obtained. *Maintenance:* 1 to 4 mg/dose up to four times a day. *Maximum:* 16 mg daily in divided doses of not more than 4 mg/dose.

***DOSAGE ADJUSTMENT*** For patients with severe renal impairment, dosage initiated at 0.5 mg before each meal and then titrated gradually, as needed. Concomitant use with clopidogrel should be avoided but if not possible, dosage initiated at 0.5 mg before each meal and total daily dose not to exceed 4 mg. Individualized dosing adjustments

needed for patients taking concomitant strong CYP2C8 or CYP3A4 inducers or CYP2C8 or CYP3A4 inhibitors. Total daily dose of 6 mg should not be exceeded in patients receiving cyclosporine.

## **Mechanism of Action**

Stimulates release of insulin from functioning pancreatic beta cells. In patients with type 2 diabetes mellitus, a shortage of these cells decreases blood insulin levels and causes glucose intolerance. By interacting with the adenosine triphosphatase (ATP)-potassium channel on the beta cell membrane, repaglinide prevents potassium from leaving the cell. This causes the beta cell to depolarize and the cell membrane's calcium channel to open. As a result, calcium moves into the cell and insulin moves out. The extent of insulin release is glucose dependent; the lower the glucose level, the less insulin is secreted from the cell.

## **Contraindications**

Concurrent therapy with gemfibrozil, hypersensitivity to repaglinide or its components

## **Interactions**

### **DRUGS**

*ACE inhibitors, angiotensin II receptor blocking agents, disopyramide, fibrates, fluoxetine, monoamine oxidase inhibitors, nonsteroidal anti-inflammatory agents (NSAIDs), pentoxifylline, pramlintide, propoxyphene, salicylates, somatostatin analogues(e.g., octreotide), and sulfonamide antibiotics:* Increased risk of hypoglycemia

*atypical antipsychotics (clozapine, olanzapine), calcium channel blockers, corticosteroids, danazol, diuretics, estrogens, glucagon, isoniazid, niacin, oral contraceptives, phenothiazines, progestogens (in oral contraceptives), protease inhibitors, somatropin, sympathomimetics (albuterol, epinephrine, terbutaline), thyroid hormones:* Possibly decreased effectiveness of repaglinide; loss of glucose control  
*beta blockers, clonidine, guanethidine, reserpine:* Possibly blunt signs and symptoms of hypoglycemia  
*cyclosporine, CYP2C8 inhibitors (clopidogrel, deferasiron, gemfibrozil, monetelukast, trimethoprim), CYP3A4 inhibitors (clarithromycin, erythromycin, ketoconazole, itraconazole):* Increased blood repaglinide level, resulting in enhanced and prolonged blood glucose-lowering effects  
*CYP2C8 and CYP3A4 inducers:* Decreased blood repaglinide level, resulting in decreased effectiveness

## Adverse Reactions

**CNS:** Headache

**CV:** Angina

**EENT:** Rhinitis, sinusitis

**ENDO:** **Hypoglycemia**

**GI:** Diarrhea, elevated liver enzymes, **hepatitis**, nausea, **pancreatitis**

**HEME:** **Hemolytic anemia, leukopenia, thrombocytopenia**

**MS:** Arthralgia, back pain

**RESP:** Bronchitis, upper respiratory tract infection

**SKIN:** Alopecia, **Stevens-Johnson syndrome**

**Other:** **Anaphylaxis**

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Drug is not recommended during breastfeeding because of the potential for hypoglycemia in the breastfed infant.

## **Nursing Considerations**

- Be aware that repaglinide shouldn't be used with NPH insulin because the combination may increase the risk of angina.
- Expect to check HbA<sub>1c</sub> level every 3 months, as ordered, to assess patient's long-term control of blood glucose level.
- During times of increased stress, such as from infection, surgery, or trauma, monitor blood glucose level often and assess need for additional insulin.

## **PATIENT TEACHING**

- Instruct patient to take repaglinide within 30 minutes before meals and to skip dose whenever she skips a meal.
- Explain that repaglinide is an adjunct to diet in managing type 2 diabetes mellitus.
- Inform patient that changes in blood glucose level may cause blurred vision or visual disturbances, especially when repaglinide therapy starts. Reassure him that these changes are usually transient.
- Teach patient how to monitor her blood glucose level and when to notify prescriber about changes.
- Review signs and symptoms of hyperglycemia and hypoglycemia with patient and family. Instruct patient to notify prescriber immediately if she

experiences anxiety, confusion, dizziness, excessive sweating, headache, increased thirst, increased urination, or nausea.

- Advise patient to wear or carry identification indicating that she has diabetes. Encourage her to carry candy or other simple carbohydrates with her to treat mild episodes of hypoglycemia.
- Inform patient that her HbA<sub>1c</sub> level will be tested every 3 to 6 months until her blood glucose level is controlled.

## reslizumab

### Cinqair

## Class and Category

*Pharmacologic class:* Interleukin-5 antagonist monoclonal antibody

*Therapeutic class:* Immunomodulator

## Indications and Dosages

- *Adjunct for add-on maintenance treatment in patients with severe asthma who have an eosinophilic phenotype*

## I.V. INFUSION

**Adults.** 3 mg/kg over 20 to 50 min once every 4 wk.

## Mechanism of Action

Inhibits IL-5 activity (the major cytokine responsible for activation and survival, differentiation, growth, and

recruitment of eosinophils) by blocking its binding to the IL-5 receptor complex found on the eosinophil cell surface. Eosinophils are among many cell types involved in inflammation. By inhibiting IL-5 signaling, the production and survival of eosinophils are reduced, which then reduces inflammation present in asthma.

## Incompatibilities

Don't mix reslizumab with any other drugs.

## Contraindications

Hypersensitivity to reslizumab or its components

## Interactions

### DRUGS

None reported

## Adverse Reactions

**EENT:** Oropharyngeal pain

**GI:** Vomiting

**MS:** Elevated CPK levels; chest, extremity, or neck musculoskeletal pain; muscle fatigue or spasms; myalgia

**RESP:** **Decreased oxygen saturation**, dyspnea, wheezing

**SKIN:** Urticaria

**Other:** **Anaphylaxis**, antibodies to reslizumab, **malignancy**

## Childbearing Considerations

## **PREGNANCY**

- It is not known if drug can cause fetal harm although monoclonal antibodies are transported across the placental barrier in a linear fashion as pregnancy progresses; therefore, potential effects on a fetus increases as the pregnancy progresses.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## **LACTATION**

- It is not known if drug is present in breast milk although human IgG is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## **Nursing Considerations**

- Know that reslizumab should not be used to treat acute asthma symptoms or acute exacerbations, including acute bronchospasm or status asthmaticus.
- Check to see that patient with an existing parasitic (helminth) infection has received treatment prior to starting reslizumab therapy because drug may interfere with resolving the infection. If patient becomes infected while receiving reslizumab and does not respond to antihelminth treatment, notify prescriber, as reslizumab will need to be discontinued until infection is resolved.
- Be aware that concurrent inhaled or systemic corticosteroid therapy should not be abruptly discontinued when reslizumab therapy is initiated, as systemic withdrawal symptoms may occur. Expect reductions to be done gradually, as ordered.
- Remove drug from refrigerator when ready to administer. To minimize foaming, do not shake vial. Inspect for particulate matter and discoloration. Know that because reslizumab is a protein, particles may be present that appear translucent to white and amorphous. Do not use if discolored or other foreign particulate matter is present. Withdraw proper volume and discard any unused portion. Inject drug slowly into an infusion bag containing 50 ml of 0.9% sodium chloride injection, USP, to minimize foaming. Know that drug is compatible with polyvinylchloride (PVC) or polyolefin infusion bags. Gently invert the bag to mix the solution. Do not

shake. Do not mix or dilute with other drugs. Administer immediately after preparing. If not used immediately, drug may be stored in diluted solution in refrigerator or at room temperature, protected from light, for up to 16 hours, which must include the time for administration.

- Make sure diluted drug, if stored in refrigerator, is brought to room temperature before administering. Use an infusion set with an in-line, low-protein-binding filter (pore size of 0.2 micron). Know that drug is compatible with polyethersulfone (PES), polyvinylidene fluoride (PVDF), nylon, and cellulose acetate in-line infusion filters. Infuse drug over 20 to 50 min according to total volume to be infused and patient's weight. Do not infuse in the same intravenous line with other agents. After infusion is complete, flush the intravenous line with 0.9% sodium chloride injection, USP. Never administer drug by intravenous push.

**WARNING** Monitor patient closely for allergic reactions to reslizumab, including anaphylaxis exhibited by decreased oxygen saturation, dyspnea, urticaria, vomiting, or wheezing. These reactions most often occurs during or within 20 minutes after completion of the infusion, although reactions have occurred before the second dose 4 weeks later. If severe symptoms, such as anaphylaxis, occur, stop infusion at once, notify prescriber, and provide supportive care, as ordered. Know that if anaphylaxis occurs, the drug should be permanently discontinued. Be aware that reslizumab specific IgE antibodies may not be detected in patients who have had a past experience of anaphylactic reactions to the drug.

- Be aware that, infrequently, malignancies of many different types have occurred within six months after patient's exposure to reslizumab. Report any persistent, severe, or unusual symptoms immediately to the prescriber.

## **PATIENT TEACHING**

- Remind patient that reslizumab is not used to treat acute asthma symptoms or acute exacerbations. If asthma symptoms worsen or become acute, instruct patient to seek immediate emergency care.

- Inform patient that drug may cause an allergic reaction that could become life-threatening. Review signs and symptoms with patient and instruct her to seek immediate emergency care, if any occurs.
- Instruct patient to have any persistent, severe, or unusual symptoms checked out by prescriber.
- Tell patient not to change any concurrent inhaled or systemic corticosteroid dosage when starting reslizumab until instructed to do so by prescriber. Inform patient that if a dosage reduction is done, it will be done gradually to avoid withdrawal symptoms. Remind her that corticosteroids should never be abruptly stopped.

## revefenacin

### Yupelri

## Class and Category

*Pharmacologic class:* Anticholinergic

*Therapeutic class:* Bronchodilator

## Indications and Dosages

- *To provide maintenance therapy for patients with chronic obstructive pulmonary disease (COPD)*

## INHALATION SOLUTION

**Adults.** 175-mcg unit-dose vial once daily by nebulizer using a mouthpiece.

## Mechanism of Action

Inhibits muscarinic receptor M3 in smooth muscles of the airways to produce bronchodilation

## Contraindications

Hypersensitivity to revefenacin or its components

## Interactions

### DRUGS

*OATP1B1 and OATP1B3 inhibitors such as cyclosporine, rifampicin:* Possibly increased systemic exposure of revefenacin leading to increased adverse reactions  
*other anticholinergics:* Possible additive anticholinergic effects leading to increased adverse reactions

## Adverse Reactions

**CNS:** Dizziness, headache

**CV:** Hypertension

**EENT:** Nasopharyngitis, oropharyngeal pain

**MS:** Back pain

**RESP:** Bronchitis, cough, **paradoxical bronchospasms**, upper respiratory infection

**Other:** **Immediate hypersensitivity reactions**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that revefenacin should not be initiated in patients during acutely deteriorating or potentially life-threatening episodes of COPD. It should also not be used to relieve acute bronchospasms; know that acute symptoms should be treated with an inhaled, short-acting beta<sub>2</sub>-agonist.
- Use cautiously in patients with narrow-angle glaucoma, because revefenacin may worsen the condition. Question patient frequently about presence of blurred vision, colored images, eye discomfort or pain, or visual halos in association with red eyes from conjunctival congestion and corneal edema. Notify prescriber immediately, if present.
- Use cautiously in patients with urinary retention, because revefenacin may worsen condition. Monitor patient for signs and symptoms of urinary retention such as difficulty passing urine or painful urination, especially in patients with bladder-neck obstruction or prostatic hyperplasia.
- Remove unit-dose vial from foil pouch and open immediately before use. Administer by the orally inhaled route via a standard jet nebulizer connected to an air compressor. Do not mix any other drugs in the nebulizer with revefenacin, as drug compatibility is unknown.
- Notify prescriber if revefenacin no longer controls symptoms of bronchoconstriction, because this may indicate that patient's condition is deteriorating and other forms of therapy may be required. The dosage or frequency of revefenacin should not be increased in this situation.

**WARNING** Monitor patient for paradoxical bronchospasm that may become life-threatening. If this should occur following a nebulizer treatment with revefenacin, notify prescriber immediately; expect to administer an inhaled, short-acting bronchodilator, as prescribed; and know that revefenacin should be discontinued immediately and alternative therapy substituted.

## PATIENT TEACHING

- Inform patient that revefenacin therapy is not meant to relieve acute symptoms of COPD and extra doses should never be used for that purpose. Instead, acute symptoms should be treated with an inhaled short-acting beta<sub>2</sub> agonist such as albuterol.
- Teach patient how to administer drug using a standard jet nebulizer. Tell patient drug should only be administered via this device. Warn him not to inject or swallow the solution and not to mix it with other medications.
- Warn patient not to inhale more than one dose at any given time. Remind him the daily dosage should not exceed one unit-dose vial. Tell him to inhale the dosage via nebulization daily at the same time every day. He should throw the plastic dispensing vials away immediately after use.
- Stress importance of keeping plastic vials out of the reach of children, because the vials' small size poses a choking danger if swallowed.
- Instruct patient to notify prescriber immediately if he experiences decreased effectiveness or needs more of his inhaled short-acting beta<sub>2</sub> agonist or experiences a decrease in lung function. Warn him not to stop taking revefenacin without consulting prescriber, as symptoms may reoccur or become worse.
- Tell patient drug may cause allergic reactions that may occur after revefenacin has been administered. Instruct patient to notify prescriber, as drug will have to be discontinued, and to seek emergency care if reaction is severe.
- Instruct patient to report the presence of blurred vision, colored images, eye discomfort or pain, or visual halos in association with red eyes from conjunctival congestion and corneal edema.
- Tell patient, especially if he has bladder-neck obstruction or prostatic hyperplasia, to report difficulty passing urine or painful urination.

**WARNING** Inform patient that drug may cause paradoxical bronchospasm. If present, patient should use an inhaled, short-acting bronchodilator immediately, stop taking revefenacin, and notify prescriber.

**ribavirin**

# Copegus, Moderiba, Rebetol, Ribasphere, Virazole

## Class and Category

*Pharmacologic class:* Nucleoside analogue

*Therapeutic class:* Antiviral

## Indications and Dosages

- *As adjunct to treat chronic hepatitis C (CHC) infection in combination with interferon alfa-2 b (pegylated and nonpegylated) in patients with compensated liver disease*

### **CAPSULES (REBETOL, RIBASPHERE), ORAL SOLUTION (REBETOL)**

**Adults weighing more than 105 kg (231 lb).** 600 mg in morning and 800 mg in evening for 24 to 48 wks depending on genotype.

**Adults weighing between 81 and 105 kg (178 to 231 lb) and children ages 3 to 18 weighing more than 73 kg (162 lb).** 600 mg in morning and 600 mg in evening for 24 to 48 wks depending on genotype.

**Adults weighing between 66 and 80 kg (145 to 177 lb) and children ages 3 to 18 weighing 60 to 73 kg (132 to 162 lb).** 400 mg in morning and 600 mg in evening for 24 to 48 wks depending on genotype.

**Adults weighing less than 66 kg (144 lb) and children ages 3 to 18 weighing between 47 and 59 kg (103 to 131 lb).** 400 mg in morning and 400 mg in evening for 24 to 48 wks depending on genotype.

## **ORAL SOLUTION (REBETOL)**

**Children ages 3 to 18 weighing less than 47 kg (103 lb).** 15 mg/kg/day divided and given in 2 doses for 24 to 48 wks depending on genotype.

- *As adjunct to treat chronic hepatitis C (CHC) infection in combination with peginterferon alfa-2a in patients with compensated liver disease who have not been previously treated with interferon alpha*

## **TABLETS (COPEGUS, MODERIBA)**

**Adults with genotypes 1 or 4 weighing 75 kg (165 lb) or more.** 600 mg in morning and 600 mg in evening for 48 wks.

**Adults with genotypes 1 or 4 weighing less than 75 kg (165 lb).** 400 mg in morning and 600 mg in evening for 48 wks.

**Adults with genotypes 2 or 3.** 400 mg in morning and 400 mg in evening for 24 wks.

**Children ages 5 to 18 weighing 75 kg (165 lb) or more.** 600 mg in morning and 600 mg in evening for 24 to 48 wks depending on genotype.

**Children ages 5 to 18 weighing 60 to 74 kg (132 to 162.8 lb).** 400 mg in morning and 600 mg in evening for 24 to 48 wks depending on genotype.

**Children ages 5 to 18 weighing 47 to 59 kg (103.4 to 129.8 lb).** 400 mg in morning and 400 mg in evening for 24 to 48 wks depending on genotype.

**Children ages 5 to 18 weighing 34 to 46 kg (74.8 to 101.2 lb).** 200 mg in morning and 400 mg in evening for 24 to 48 wks depending on genotype.

**Children ages 5 to 18 weighing 23 to 33 kg (50.6 to 72.6 lb).** 200 mg in morning and 200 mg in evening for 24 to 48 wks depending on genotype.

- *To treat hospitalized infants and young children with severe lower respiratory tract infections due to respiratory syncytial virus (RSV)*

## **INHALATION SOLUTION (VIRAZOLE)**

**Hospitalized infants and young children.** 20 mg/ml administered by SPAG-2 unit with continuous aerosol for 12 to 18 hr daily for 3 to 7 days.

***DOSAGE ADJUSTMENT*** Dosage adjustment individualized for patients with renal dysfunction and severe adverse reactions.

## **Mechanism of Action**

Precise action unknown, but may inhibit HCV polymerase or respiratory syncytial virus in a selective biochemical reaction.

## **Contraindications**

Autoimmune hepatitis, coadministration with didanosine, creatinine clearance less than 50 ml/min, hemoglobinopathies (i.e., sickle-cell anemia, thalassemia major), hypersensitivity to ribavirin or its components, men whose female partners are pregnant, pregnancy

## **Interactions**

### **DRUGS**

*azathioprine:* Increased risk of azathioprine-related myelotoxicity and severe pancytopenia

*didanosine:* Increased risk of didanosine-induced toxicities such as hepatic failure, pancreatitis, peripheral

neuropathy, and symptomatic hyperlactatemia/lactic acidosis

*lamivudine, stavudine, zidovudine*: Possibly decreased effectiveness of these drugs; increased risk of hepatic toxicity, anemia, and hepatic decompensation

## Adverse Reactions

**CNS:** Aggression, agitation, anger, anxiety, asthenia, chills, **CVA**, depression, dizziness, emotional swings in mood, fatigue, fever, hallucinations, headache, impaired concentration, insomnia, irritability, lethargy, malaise, memory impairment, nervousness, peripheral neuropathy, psychosis, rigors, **suicidal ideation**, vertigo

**CV:** Angina, **bigeminy**, **bradycardia** (inhalation solution), **cardiac arrest**, chest pain, **hypotension** (inhalation solution)

**EENT:** Blurred vision, conjunctivitis, dry mouth, hearing impairment or loss, pharyngitis, retinal detachment or exudates, rhinitis, significant ophthalmologic disorders, sinusitis, taste perversion, transient blindness

**ENDO:** Hyperglycemia, hypothyroidism, growth retardation (children)

**GI:** Abdominal pain, anorexia, cholangitis, colitis, constipation, diarrhea, dyspepsia, elevated liver enzymes, fatty liver, **GI bleeding**, **hepatic decompensation**, hepatomegaly, hyperbilirubinemia, nausea, **pancreatitis**, peptic ulcer, vomiting

**GU:** Menstrual disorder

**HEME:** Anemia, **hemolytic anemia**, **leukopenia**, **neutropenia**, **pure red cell aplasia**, reticulocytosis (inhalation solution), **thrombocytopenia**, **thrombotic thrombocytopenic purpura**

**MS:** Arthralgia, back pain, extremity pain, musculoskeletal pain, myalgia, myositis

**RESP:** Cough, dyspnea, **pulmonary embolism or hypertension** (inhalation solution in children); **apnea, atelectasis**, bacterial pneumonia, **bronchospasm, cyanosis**, dyspnea, **hypoventilation, pneumothorax, pulmonary edema, ventilator dependence, worsening of respiratory status** (inhalation solution)

**SKIN:** Alopecia, dermatitis, diaphoresis, dry skin, eczema, erythroderma, flushing, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis; angioedema**; autoimmune disorders; bacterial, fungal, or viral infections; dehydration; flu-like symptoms; graft rejection (liver or renal); hyperuricemia; weight loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-593-2214.
- Drug can cause fetal harm as significant embryocidal and teratogenic effects.
- A negative pregnancy must be obtained immediately before drug therapy is begun and periodic pregnancy tests done during treatment and for 6 months following discontinuation of drug.
- Drug is contraindicated in women who are pregnant and in male partners of women who are pregnant. If pregnancy occurs, drug must be discontinued immediately.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

### REPRODUCTION

- Females of childbearing age and male patients and their female partners of childbearing should use effective contraception during drug therapy and during 6 months after drug has been discontinued.
- Drug may impair male fertility.

## Nursing Considerations

- Know that patient requires the following tests to be performed before ribavirin therapy is started and then periodically thereafter, as ordered, to establish a baseline before treatment starts and allow early detection of adverse effects during treatment: ECG, standard hematologic tests including hemoglobin, liver function tests, monthly pregnancy tests for women of childbearing potential or partners of male patients, and TSH levels. Expect dosage to be temporarily withheld or discontinued, as ordered, if patient experiences severe adverse reactions or test abnormalities and drug to be discontinued immediately with confirmation of pregnancy.
- Be aware that ribavirin therapy should not be given to patients with a creatinine clearance less than 50 ml/min, because of risk of severe renal dysfunction. Ribavirin should not be given until a negative pregnancy test is obtained from women of childbearing age or the female partner of childbearing age of male patient. Also know that ribavirin should not be given to patient with a history of significant or unstable cardiac disease, because drug may cause a deterioration of cardiovascular status.
- Use caution when administering ribavirin to patient with preexisting but stable cardiac disease. Monitor these patients closely and expect that if there is any deterioration in cardiovascular status, ribavirin therapy will be discontinued.
- Be aware that the aerosol solution of ribavirin is for use in children only. It should not be mixed with or simultaneously given with other aerosolized medications. To prepare the powder for administration as a solution, reconstitute drug with a minimum of 75 ml of sterile water for injection, USP or inhalation in the original 100-ml glass vial. Shake well. Transfer solution to the clean, sterilized 500-ml SPAG-2 reservoir and further dilute to a final volume of 300 ml with sterile water for injection, USP or inhalation. The final concentration should be 20 mg/ml. Discard solutions in the SPAG-2 unit at least every 24 hours and when the liquid level is low before adding newly reconstituted solution.
- Monitor patients with impaired renal function and those over the age of 50 during therapy for anemia. Because anemia usually occurs early in treatment, expect to obtain a baseline of patient's hemoglobin and then

assess at 2 and 4 weeks after therapy begins. Know that any patient who develops a decreased hemoglobin level below 10 g/dl should have dosage modified or drug discontinued, as ordered, because potentially fatal myocardial infarctions have occurred from anemia induced by ribavirin therapy. For patients with a history of stable cardiovascular disease, expect a permanent dosage reduction to occur if the hemoglobin decreases by more than or equal to 2 g/dl during any 4-week period. If the hemoglobin remains less than 12 g/dl after 4 weeks of therapy on a reduced dose, expect drug to be discontinued. Also monitor patient taking azathioprine concomitantly for pancytopenia and bone marrow suppression, which usually occurs within 3 to 7 weeks after concomitant administration of pegylated interferon/ribavirin and azathioprine. Expect drug to be discontinued if pancytopenia develops.

- Monitor patient for signs and symptoms of pancreatitis (abdominal pain and tenderness, anorexia, fever, nausea, vomiting). If present, notify prescriber and expect drug to be discontinued.
- Expect patient's lungs to be assessed regularly for evidence of pulmonary function impairment or pulmonary infiltrates. If either develops, expect ribavirin therapy to be discontinued.
- Know that because ribavirin is used in conjunction with alpha interferons, serious and severe visual changes may occur. Know that patient should have a baseline ophthalmologic exam before therapy begins. Patients with preexisting ophthalmologic disorders such as diabetic or hypertensive retinopathy should receive periodic eye examinations throughout therapy or at any time ocular symptoms appear. Expect drug to be discontinued in patients who develop new or worsening ophthalmologic disorders.

## PATIENT TEACHING

- Instruct patient to take ribavirin exactly as prescribed. If a dose is missed, tell patient to take the missed dose as soon as possible during the same day but not to double the next dose.
- Warn patient not to break open or crush Rebetol capsules.
- Tell patient to take oral ribavirin with food.

**WARNING** Instruct patients to use two reliable forms of contraception throughout treatment, because drug can cause fetal harm even in partner of male patient. Inform them that a pregnancy test must be performed monthly during ribavirin therapy and for 6 months after

therapy is finished. Stress importance of notifying prescriber immediately if pregnancy occurs or is suspected.

- Instruct patient to comply with dental checkups and to brush teeth thoroughly twice daily. If vomiting should occur, stress importance of rinsing out mouth thoroughly afterward.
- Inform patients that growth retardation often occurs with combination therapy that includes ribavirin. Reassure parents that following treatment, rebound growth and weight gain occur in most children.
- Stress importance of complying with scheduled laboratory tests.
- Tell patient to maintain adequate hydration throughout ribavirin therapy.
- Caution patient not to perform hazardous activities such as driving until effects of ribavirin on his nervous system are known and resolved.
- Caution patient or parents to watch for changes in behavior or mood as ribavirin may cause suicidal ideation. If changes are noted, stress importance of contacting prescriber.

## rifampin

(rifampicin)

**Rifadin, Rifadin IV, Rimactane, Rofact (CAN)**

### **Class and Category**

*Pharmacologic class:* Semisynthetic rifamycin

*Therapeutic class:* Antimycobacterial antitubercular

### **Indications and Dosages**

- *As adjunct to treat tuberculosis caused by all strains of Mycobacterium tuberculosis*

## **CAPSULES, ORAL SUSPENSION, I.V. INFUSION**

**Adults.** 10 mg/kg daily with other antitubercular drugs for 2 mo. with oral dosage given 1 hr before or 2 hr after a meal and IV dosage given over 3 hr if diluted in 500 ml of D5W or 30 min if diluted in 100 ml of D5W *Maximum:* 600 mg daily.

**Children.** 10 to 20 mg/kg daily in combination with other antitubercular drugs for 2 mo, with oral dosage given 1 hr before or 2 hr after a meal and IV dosage given over 3 hr if diluted in 500 ml of D5W or 30 min if diluted in 100 ml of D5W. *Maximum:* 600 mg daily.

- *To eliminate meningococci from nasopharynx of asymptomatic carriers of Neisseria meningitidis*

## **CAPSULES, ORAL SUSPENSION**

**Adults.** 600 mg every 12 hr for 2 days (total of 4 doses) with oral dosage given 1 hr before or 2 hr after a meal and IV dosage given over 3 hr if diluted in 500 ml of D5W or 30 min if diluted in 100 ml of D5W.

**Infants age 1 month and over and children.** 10 mg/kg every 12 hr for 2 days (total of 4 doses). *Maximum:* 600 mg/dose.

**Infants under age 1 month.** 5 mg/kg every 12 hr for 2 days (total of 4 doses).

## **Mechanism of Action**

Inhibits bacterial and mycobacterial RNA synthesis by binding to DNA-dependent RNA polymerase, thereby blocking RNA transcription. Exhibits dose-dependent bactericidal or bacteriostatic action. Rifampin is highly

effective against rapidly dividing bacilli in extracellular cavitory lesions, such as those found in the nasopharynx.

## Incompatibilities

Don't administer rifampin in the same I.V. line as diltiazem.

## Contraindications

Concurrent use of atazanavir, darunavir, fosamprenavir, praziquantel, ritonavir/saquinavir, saquinavir, or tipranavir; hypersensitivity to rifampin, other rifamycins or their components

## Interactions

### DRUGS

*antacids*: Possibly reduced rifampin absorption  
*antiarrhythmics* (disopyramide, mexiletine, quinidine, propafenone, tocainide), *anticonvulsants* (phenytoin), *antiestrogens* (tamoxifen, toremifene), *antifungals* (fluconazole, itraconazole, ketoconazole), *antipsychotics* (haloperidol), *antiretrovirals* (atazanavir, darunavir, efavirenz, fosamprenavir, indinavir, saquinavir, tipranavir, zidovudine), *benzodiazepines* (diazepam), *benzodiazepine-related drugs* (zopiclone, zolpidem), *beta blockers* (metoprolol, propranolol), *calcium channel blockers* (diltiazem, nifedipine, verapamil), *chloramphenicol*, *clarithromycin*, *corticosteroids* (prednisolone), *dapsone*, *digoxin*, *doxycycline*, *enalapril*, *fluoroquinolones* (moxifloxacin, perfloxacin), *hepatitis C antiviral* (daclatasvir, simeprevir, sofosbuvir, telaprevir), *hypoglycemic agents oral* (glipizide, glyburide), *immunosuppressive agents* (cyclosporine, tacrolimus),

*irinotecan, levothyroxine, losartan, methadone, narcotic analgesics (morphine, oxycodone), praziquantel, quinine, selective 5-HT<sub>3</sub> receptor antagonists (ondansetron), statins (simvastatin), systemic hormonal contraceptives (estrogens, progestins), telithromycin, theophylline, thiazolidinediones (rosiglitazone), tricyclic antidepressants (nortriptyline), warfarin*: Decreased exposure and effectiveness of these drugs  
*atovaquone*: Decreased concentration of atovaquone and increased concentration of rifampin, which may increase risk of toxicities  
*cotrimoxazole, probenecid*: Increased rifampin concentration  
*halothane, isoniazid*: Possibly hepatotoxicity  
*ritonavir/saquinavir*: Increased risk of severe hepatotoxicity

## ACTIVITIES

*alcohol use*: Increased risk of hepatotoxicity

## Adverse Reactions

**CNS:** Ataxia, behavioral changes, chills, confusion, difficulty concentrating, dizziness, drowsiness, fatigue, fever, generalized numbness, headache, paresthesia, psychoses

**CV:** **Hypotension**, **myopathy**, vasculitis

**EENT:** Conjunctivitis; discolored saliva, sputum, tears, and teeth; mouth or tongue soreness; periorbital edema; visual disturbances

**ENDO:** **Adrenal insufficiency** (rare), hyperglycemia or **hypoglycemia** (in patients with diabetes)

**GI:** Abdominal cramps, anorexia, cholestasis, diarrhea, discolored feces, elevated liver enzymes, epigastric discomfort, flatulence, heartburn, **hepatitis**, jaundice,

nausea, **pseudomembranous colitis**, **shock-like syndrome with hepatic involvement**, vomiting

**GU: Acute renal failure or tubular necrosis**, discolored urine, elevated BUN and serum uric acid, hematuria, interstitial nephritis, menstrual disturbances, **renal insufficiency**

**HEME: Agranulocytosis** (rare), decreased hemoglobin, **disseminated intravascular coagulation (DIC)**, eosinophilia, **hemolytic anemia**, **leukopenia**, **neutropenia**, purpura, **thrombocytopenia** (rare)

**MS: Arthralgia**, extremity pain, muscle weakness, myalgia (rare)

**RESP: Acute bronchospasm**, shortness of breath, wheezing

**SKIN: Acute generalized exanthematous pustulosis**, discolored skin and sweat, **erythema multiforme**, flushing, pemphigoid reaction, pruritus, rash, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other: Anaphylaxis**, **angioedema**, **drug reaction with eosinophilia and systemic symptoms (DRESS)**, flu-like symptoms, lymphadenopathy

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm but drug does cross the placental barrier. When given during the last few weeks of pregnancy drug can cause postnatal hemorrhages in both mother and infant.
- Drug is not recommended for use during pregnancy or in women of childbearing age unless an alternative treatment is not available.

### LACTATION

- Drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions.

## Nursing Considerations

- Obtain blood samples or other specimens for culture and sensitivity testing, as ordered, before giving rifampin and throughout therapy to monitor response to drug.
- Be aware that rifampin should not be used to treat meningococcal infection, because of the possibility of rapid emergence of resistant organisms.

**WARNING** Expect to monitor liver enzymes and every 2 to 4 weeks during therapy. Immediately report abnormalities. Also monitor patient for liver dysfunction such as abdominal pain, darkened urine, loss of appetite, and yellowish discoloration of the eyes and skin. Know that drug can cause serious liver dysfunction that could become life-threatening.

- Use rifampin cautiously in patients with diabetes mellitus because rifampin therapy may make diabetes management more difficult because of its effect on blood glucose levels.
- For I.V. infusion, reconstitute by adding 10 ml sterile water for injection to 600-mg vial of rifampin. Swirl gently to dissolve. Withdraw appropriate dose and add to 500 ml D<sub>5</sub>W (preferred solution) or normal saline solution and infuse over 3 hours. Or, withdraw appropriate dose and add to 100 ml D<sub>5</sub>W (preferred solution) or normal saline solution and infuse over 30 minutes. Use reconstituted drug promptly because rifampin may precipitate out of D<sub>5</sub>W solution after 4 hours. In normal saline solution, drug is stable up to 24 hours at room temperature.
- Expect drug to discolor body fluids, skin, and teeth reddish orange to reddish brown.
- Be aware that rifampin can cause myelosuppression and increase risk of infection. Notify prescriber immediately if signs of infection, such as fever, develop.

- Monitor patient for signs and symptoms of hypersensitivity reactions. Notify prescriber if present, expect drug to be discontinued, and provide supportive care, as ordered.
- Monitor patient for rash or other skin abnormalities, as rifampin may cause severe skin reactions that could be life-threatening.

## **PATIENT TEACHING**

- Instruct patient to take rifampin 1 hour before or 2 hours after a meal with a full glass of water.
- Emphasize the need to take drug exactly as prescribed. Explain that not completing the full course of therapy or skipping doses may decrease the effectiveness of the treatment and increase the chance that resistance to drug may develop, making it ineffective to treat an infection patient might develop in the future. Emphasize importance of compliance with the full course of therapy.
- Explain that drug may discolor feces, saliva, skin, sputum, sweat, tears, teeth, and urine reddish brown to reddish orange or yellow. Discoloration of teeth and soft contact lenses may be permanent.
- Advise patient who takes an oral contraceptive to use an additional form of birth control during rifampin therapy.
- Urge patient to notify prescriber about anorexia, cough, darkened urine, fever, flu-like symptoms, joint pain or swelling, malaise, nausea, rash, shortness of breath, swollen lymph nodes, vomiting, wheezing, and yellowish eyes or skin.
- Advise patient to avoid alcohol, herbal products, or any drug that adversely affects the liver (without prescriber consent) during rifampin therapy.
- Instruct patient to notify prescriber if no improvement occurs within 2 to 3 weeks.
- Inform patient with diabetes mellitus that rifampin therapy may affect his blood glucose levels and to monitor his blood glucose levels closely.
- Tell patient to inform all prescribers of rifampin therapy.
- Instruct patient to notify prescriber immediately if rash or other skin abnormalities occur, as reaction may become severe.

# rifamycin

**Aemcolo**

## Class and Category

*Pharmacologic class:* Rifamycin antibacterial

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat travelers' diarrhea caused by noninvasive strains of Escherichia coli*

### D.R. TABLETS

**Adults.** 388 mg twice daily (in morning and evening) for 3 days.

## Mechanism of Action

As a semisynthetic derivative of rifampin, drug inhibits bacterial RNA synthesis by binding to DNA-dependent RNA polymerase, thereby blocking RNA transcription. This results in bacterial cell impairment or death.

## Contraindications

Hypersensitivity to rifamycin, other rifamycin-class antimicrobial agents such as rifaximin, or their components

## Interactions

## DRUGS

None reported

## Adverse Reactions

**CNS:** Fever, headache

**GI:** Abdominal pain, *Clostridium difficile*-associated diarrhea, constipation, dyspepsia

## Childbearing Considerations

### PREGNANCY

- It is not known if drug causes fetal harm. However, because systemic absorption is negligible, it not expected to affect the fetus.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Be aware that rifamycin is not to be used in patients with diarrhea complicated by bloody stool or fever or due to pathogens other than noninvasive strains of *E. coli*.
- Administer rifamycin with 6 to 8 ounces of liquid.
- Know that drug should be discontinued if diarrhea gets worse or persists more than 48 hours.
- Assess patient for signs of secondary infection, such as profuse, watery diarrhea. If such diarrhea develops, contact prescriber and expect to obtain a stool specimen to rule out pseudomembranous colitis caused

by *Clostridium difficile*. If diarrhea occurs, notify prescriber and expect to withhold rifamycin and treat with electrolytes, fluids, protein, and an antibiotic effective against *C. difficile*.

## PATIENT TEACHING

- Tell patient to take rifamycin twice daily (once in morning and once in evening) with 6 to 8 ounces of liquid but not with alcohol.
- Caution patient not to break, chew, or crush tablets. Instead, tablets must be swallowed whole.
- Instruct patient to notify prescriber if diarrhea gets worse or persists for more than 48 hours, because drug will have to be discontinued and a different antibiotic prescribed.

**rifaximin**

**Xifaxan**

## Class and Category

*Pharmacologic class:* Rifamycin

*Therapeutic class:* Antibiotic

## Indications and Dosages

- *To treat irritable bowel syndrome with diarrhea (IBS-D)*

### **TABLETS**

**Adults.** 550 mg three times daily for 14 days. May be repeated up to two times for reoccurrence.

- *To treat travelers' diarrhea caused by noninvasive strains of Escherichia coli*

## **TABLETS**

**Adults and children age 12 and over.** 200 mg three times daily for 3 days.

- *To reduce risk of overt hepatic encephalopathy*

## **TABLETS**

**Adults.** 550 mg twice daily.

## **Mechanism of Action**

As a semisynthetic derivative of rifampin, it inhibits bacterial RNA synthesis by binding to DNA-dependent RNA polymerase, thereby blocking RNA transcription. This results in bacterial cell impairment or death.

## **Contraindications**

Hypersensitivity to rifaximin, any of the rifamycin antimicrobial agents, or their components

## **Interactions**

### **DRUGS**

*P-glycoprotein inhibitors such as cyclosporine:* Increased exposure to rifaximin leading to possible risk of increased adverse reactions

*warfarin:* Altered INR levels possibly requiring warfarin dosage adjustment

# Adverse Reactions

**CNS:** Depression, dizziness, fatigue, fever, headache

**CV:** Peripheral edema

**EENT:** Nasal passage irritation, nasopharyngitis, taste loss

**GI:** Abdominal pain, anorexia, ascites, *Clostridium difficile-associated colitis*, *dysentery*, elevated ALT liver enzyme, nausea

**HEME:** Anemia

**MS:** Arthralgia, muscle spasms, myalgia

**RESP:** Dyspnea

**SKIN:** *Exfoliative dermatitis*, flushing, pruritus, rash, urticaria

**Other:** *Anaphylaxis*, *angioedema*, elevated blood creatine phosphokinase, weight loss

# Childbearing Considerations

## PREGNANCY

- It is not known if drug can cause fetal harm.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

## LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

# Nursing Considerations

- Be aware that rifaximin should not be used in patients with travelers' diarrhea complicated by blood in the stool, diarrhea due to pathogens other than *E. coli*, or in the presence of fever.

- Use extreme caution in patients with severe hepatic impairment because of increased rifaximin exposure leading to possible increased risk of adverse reactions.
- Notify prescriber if diarrhea gets worse or persist for more than 48 hours in patients being treated for diarrhea or for a new onset of diarrhea in patients being treated for hepatic encephalopathy. The patient may be experiencing *C. difficile* colitis associated with antibiotic use requiring rifaximin to be discontinued and an antibiotic effective against *C. difficile* along with electrolytes, fluids, and protein replacement therapy, to be administered, as ordered.

## PATIENT TEACHING

- Instruct patient to take drug for length of time prescribed, even when feeling better.
- Tell patient to report diarrhea that gets worse or persists for more than 48 hours or new onset or reoccurrence of diarrhea as *C. difficile*-associated diarrhea may occur even after rifaximin has been discontinued requiring additional treatment.

**rilpivirine**

**Edurant**

## Class and Category

*Pharmacologic class:* Nonnucleoside reverse transcriptase inhibitor (NNRTI)

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency virus type 1 (HIV-1) infection in antiretroviral treatment-*

*naïve patients with HIV-1 RNA equal to or less than 100,000 copies/ml at the start of therapy*

## **TABLETS**

**Adults and children age 12 years and over weighing at least 35 kg (77 lb).** 25 mg once daily with food.

***DOSAGE ADJUSTMENT*** For patient taking rifabutin concomitantly, dosage increased to 50 mg once daily with a meal.

## **Mechanism of Action**

Inhibits HIV-1 replication by noncompetitive inhibition of HIV-1 reverse transcriptase.

## **Contraindications**

Concomitant therapy with carbamazepine, dexamethasone (more than a single dose), esomeprazole, lansoprazole, omeprazole, oxcarbazepine, pantoprazole, phenobarbital, phenytoin, rabeprazole, rifampin, rifapentine, or St. John's wort; hypersensitivity to rilpivirine or its components

## **Interactions**

### **DRUGS**

*aluminum- or magnesium-containing antacids, calcium carbonate, cimetidine, famotidine:* Decreased rilpivirine concentration and significantly decreased effectiveness  
*atazanavir, atazanavir/ritonavir, clarithromycin, darunavir/ritonavir, delavirdine, erythromycin, fluconazole, fosamprenavir, fosamprenavir/ritonavir, indinavir, itraconazole, lopinavir/ritonavir, nelfinavir, posaconazole,*

*saquinavir/ritonavir, telithromycin, tipranavir, voriconazole:* Increased concentration of rilpivirine with possible prolonged action and risk of adverse reactions  
*carbamazepine, dexamethasone (more than a single-dose), phenobarbital, phenytoin, proton pump inhibitors, rifampin, rifapentine, St. John's wort:* Possibly significant decrease in rilpivirine plasma concentrations, resulting in loss of virologic response  
*drugs that prolong QT interval:* Increased risk of torsades de pointes  
*ketoconazole:* Decreased ketoconazole concentration and effectiveness and increased rilpivirine concentration with possible prolonged action and risk of adverse reactions  
*methadone:* Possible decreased methadone concentration with increased risk of opiate withdrawal  
*other NNRTIs (efavirenz, etravirine, nevirapine), rifabutin:* Decreased concentration of rilpivirine with possible decreased effectiveness

## Adverse Reactions

**CNS:** Abnormal dreams, anxiety, depression, dizziness, dysphoria, fatigue, fever, headache, insomnia, mood changes, sleep disorders, somnolence, **suicidal ideation**

**CV:** Elevated cholesterol and triglycerides

**EENT:** Conjunctivitis, oral ulceration

**ENDO:** Cushingoid appearance, fat redistribution

**GI:** Abdominal discomfort or pain, anorexia, bilirubin increase, cholecystitis, cholelithiasis, diarrhea, elevated liver enzymes, **hepatitis, hepatotoxicity**, nausea, vomiting

**GU:** Elevated creatinine, glomerulonephritis, nephrolithiasis, **nephrotic syndrome**

**HEME:** Eosinophilia

**SKIN:** Blisters, rash

**Other:** Angioedema, drug reaction with eosinophilia and systemic symptoms (DRESS), immune reconstitution syndrome

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- Drug can be administered during pregnancy.

### LACTATION

- It is not known if drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Administer rilpivirine with a meal. Know that a protein drink does not replace a meal.
- Know that drug should not be used in patients taking other medications with a known risk of torsades de pointes or in patients at higher risk of torsades de pointes, because rilpivirine may cause QT prolongation.

**WARNING** Obtain liver enzymes before therapy begins, as ordered, in patients with marked transaminase elevations, patients treated with other medications associated with liver toxicity, and patients with underlying hepatic disease, including hepatitis B or C viral infections. Also monitor liver enzymes throughout therapy, as ordered, on all patients, because rilpivirine may cause hepatotoxicity. Know that persistent

elevations of serum transaminase levels may require rilpivirine therapy to be discontinued.

- Obtain cholesterol and triglyceride levels before rilpivirine is begun and periodically throughout therapy, because drug may cause an increase in total cholesterol and triglycerides.

**WARNING** Assess patient's skin regularly for rash or other abnormalities. Notify prescriber and expect rilpivirine to be discontinued immediately if a severe rash occurs and is accompanied by blisters, conjunctivitis, eosinophilia, facial edema, fever, joint or muscle aches, lip swelling, malaise, or oral lesions. Be aware that a delay in discontinuing the drug may result in a life-threatening situation.

- Monitor patient's mood and emotional status, as rilpivirine may cause significant depression, mood changes, and suicidal ideation. Report any changes to prescriber.
- Be aware that immune reconstitution syndrome has occurred in patients treated with combination antiretroviral therapy, including rilpivirine. The inflammatory response predisposes susceptible patients to opportunistic infections such as cytomegalovirus, *Mycobacterium avium* infection, *Pneumocystis jiroveci* pneumonia, or tuberculosis. Autoimmune disorders such as Graves' disease, Guillain-Barré syndrome, or polymyositis have also occurred. Report sudden or unusual adverse reactions to prescriber.

## PATIENT TEACHING

- Advise patient to avoid missing doses of rilpivirine. If she misses a dose, she should take it as soon as she remembers, but should not double the next dose or take more than prescribed.
- Inform patient that rilpivirine must be taken with a meal. Remind patient that a protein drink does not replace a meal.

**WARNING** Inform patient about severe liver disease that may occur with rilpivirine. Tell her to report signs and symptoms of liver disease such as acholic stools,

anorexia, fatigue, malaise, nausea, tenderness over liver area, or yellowing of skin or whites of the eyes and to seek immediate medical attention.

- Stress importance of being compliant with tests ordered to screen for adverse effects of rilpivirine therapy.

**WARNING** Advise patient that rilpivirine therapy may cause severe hypersensitivity or skin reactions. Tell her to report a rash, especially if it is accompanied by blisters, conjunctivitis, facial edema, fatigue, fever, joint or muscle aches, liver problems, or oral lesions and to seek immediate medical attention.

- Inform patient that rilpivirine therapy may cause changes in her body appearance because of fat redistribution. Prepare her for the possibility of developing breast enlargement, central obesity, dorsocervical fat enlargement (buffalo hump), facial wasting, and peripheral wasting.
- Instruct patient to report any persistent, severe, or unusual signs and symptoms.
- Encourage women of childbearing age to report known or suspected pregnancy. If pregnancy occurs, encourage patient to enroll in the Antiretroviral Pregnancy Registry by calling 1-800-258-4263.
- Alert mothers that breastfeeding is not recommended during rilpivirine therapy.
- Tell patient to report all drugs being taken, including over-the-counter medications and herbals, as serious drug interactions may occur. Advise patient not to begin any new drug therapy without first checking with prescriber.
- Tell patient or caregiver to report any signs of depression, mood changes, sleep disorders, or suicidal thoughts to prescriber.

**risankizumab-rzaa**

# Skyrizi

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Anti-inflammatory, immunosuppressant

## Indications and Dosages

- *To treat moderate to severe plaque psoriasis in patients who are candidates for systemic therapy or phototherapy*

## SUBCUTANEOUS INJECTION

**Adults.** *Initial:* 150 mg (two consecutive 75-mg injections) followed by 150 mg (two consecutive 75-mg injections) 4 wk later and then 150 mg (two consecutive 75-mg injections) every 12 wk thereafter.

## Mechanism of Action

Unknown but thought to block interleukin-23, which causes inflammation and swelling, reducing the signs and symptoms of plaque psoriasis

## Contraindications

Hypersensitivity to risankizumab-rzaa or its components

## Interactions

## DRUGS

*immunosuppressants*: enhanced immunosuppressive effect  
*live vaccines*: Possibly increased risk of infection

## Adverse Reactions

**CNS:** Fatigue, headache

**MS:** Asthenia, osteomyelitis

**RESP:** Pneumonia, upper respiratory infections

**SKIN:** Cellulitis

**Other:** Antibody formation to risankizumab-rzaa; infections, including herpes zoster and tinea; injection-site reactions such as bruising, erythema, extravasation, hematoma, hemorrhage, infection, inflammation, irritation, pain, pruritus, swelling, warmth; **sepsis**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm, but drug does cross the placental barrier and may be transmitted from mother to fetus.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- Patient should check with prescriber before breastfeeding.

## Nursing Considerations

- Know that risankizumab-rzaa should not be given to patient with an active infection until infection resolves or is adequately treated.

- Use risankizumab-rzaa cautiously in patients with chronic infection or a history of recurrent infection.
- Be sure patient has been evaluated for tuberculosis prior to initiating treatment with risankizumab-rzaa. Expect tuberculosis treatment to be initiated in patients with a past history of active or latent TB in whom an adequate course of treatment cannot be confirmed. Monitor patient for signs and symptoms of active TB during and after drug therapy. Know that risankizumab-rzaa should not be given to patients with active TB.
- Check to determine that patient is up to date on immunizations before initiating treatment with risankizumab-rzaa.
- Inject risankizumab-rzaa as two separate 75-mg injections using the single-dose prefilled syringes for the full 150-mg dose. Administer each injection at a different anatomic location, such as the abdomen or thigh, and not into areas where skin is bruised, erythematous, indurated, tender, or affected by psoriasis. Know that the upper, outer arm may be used as an injection site by a healthcare professional.
- Institute infection control measures and monitor patient for signs and symptoms of infection throughout therapy. Notify prescriber if an infection is suspected or known and expect drug to be withheld until infection is resolved.

## **PATIENT TEACHING**

- Teach patient or caregiver how to administer a subcutaneous injection. Instruct patient or caregiver to first take drug carton out of the refrigerator and allow it to warm at room temperature out of direct sunlight (15 to 30 minutes) without removing the prefilled syringes from the carton. After visually inspecting syringes for particulate matter and discoloration (solution should be colorless to slightly yellow and clear to slightly opalescent), tell patient or caregiver to administer two separate 75-mg single-dose prefilled syringes for the full 150-mg dose by injecting into the abdomen or thigh and not into an area that is bruised, red, indurated, tender, or affected by psoriasis. Caregiver may inject drug into patient's upper, outer arm. Remind patient or caregiver to inject the two injections at different anatomic locations. Instruct patient or caregiver how to dispose of needle and syringe properly.
- Instruct patient or caregiver that if a dose is missed, to administer it as soon as possible and then resume dosing at the regular time.
- Review infection control measures with patient and family. Urge patient to notify prescriber immediately if an infection is suspected or known.

# risedronate sodium

**Actonel, Atelvia**

## Class and Category

*Pharmacologic class:* Bisphosphonate

*Therapeutic class:* Antiosteoporotic

## Indications and Dosages

- *To treat Paget's disease of bone*

### **TABLETS (ACTONEL)**

**Adults.** 30 mg at least 30 min before the first drink or food of the day other than water daily for 2 mo. Repeated after 2 mo if relapse occurs or if serum alkaline phosphatase level fails to normalize.

- *To prevent or treat glucocorticoid-induced osteoporosis*

### **TABLETS (ACTONEL)**

**Adults.** 5 mg at least 30 min before the first drink or food of the day other than water) daily.

- *To prevent or treat postmenopausal osteoporosis*

### **TABLETS (ACTONEL)**

**Postmenopausal women.** 5 mg daily. Or, 35 mg once weekly, 75 mg taken on 2 consecutive days once a month,

or 150 mg once a month. Drug taken at least 30 min before the first drink or food of the day other than water.

➤ *To treat osteoporosis in women*

## **E.R. TABLETS (ATELVIA)**

**Adults.** 35 mg (1 tablet) immediately following breakfast once weekly.

➤ *To treat osteoporosis in men*

## **TABLETS (ACTONEL)**

**Adult men.** 35 mg at least 30 min before the first drink or food of the day other than water once weekly.

Route	Onset	Peak	Duration
P.O.	Unknown	3 mo	16 mo

## **Mechanism of Action**

Hinders excessive bone remodeling characteristic of Paget's disease by binding to bone and reducing the rate at which osteoclasts are resorbed by bone. Also, decreases elevated rate of bone turnover that is typically seen in osteoporosis.

## **Contraindications**

Esophageal abnormalities that delay esophageal emptying, such as achalasia or stricture; hypersensitivity to risedronate or its components; hypocalcemia; inability to sit or stand upright for at least 30 minutes

## **Interactions**

## DRUGS

*angiogenesis inhibitors, chemotherapy, corticosteroids:*

Possibly increased risk of osteonecrosis of the jaw

*aspirin, NSAIDs:* Increased risk of GI irritation

*calcium-containing preparations, including antacids:*

Impaired absorption of risedronate

*histamine<sub>2</sub> blockers, proton pump inhibitors:* Faster drug

release of delayed released form of drug increasing drug exposure and possible adverse reactions

## FOODS

*all foods:* Decreased risedronate bioavailability when taking Actonel form of drug

## Adverse Reactions

**CNS:** Anxiety, asthenia, depression, dizziness, fatigue, headache, insomnia, sciatica, syncope, vertigo, weakness

**CV:** Chest pain, hypercholesterolemia, hypertension, peripheral edema, vasodilation

**EENT:** Amblyopia, cataract, dry eyes, eye inflammation, nasopharyngitis, painful swallowing, pharyngitis, rhinitis, sinusitis, tinnitus

**GI:** Abdominal pain, colitis, constipation, diarrhea, dyspepsia, dysphagia, eructation, esophagitis, esophageal or gastric ulcers, flatulence, gastritis, nausea, vomiting

**GU:** UTI

**MS:** Arthralgia; atypical femur fractures; back, limb, neck, or shoulder pain; jaw osteonecrosis; leg cramps or spasms; myasthenia; myalgia; osteoarthritis; retrosternal pain; severe incapacitating bone, joint, or muscle pain

**RESP:** **Asthma exacerbation**; bronchitis, cough, pneumonia, upper respiratory tract infection

**SKIN:** Bullous reaction, pruritus, rash, **Stevens-Johnson syndrome, toxic epidermal necrolysis**

**Other:** **Anaphylaxis, angioedema**, flu-like symptoms, **hypersensitivity reactions, hypocalcemia**

## Childbearing Considerations

### PREGNANCY

- It is not known if drug can cause fetal harm.
- Know that there is a theoretical risk of fetal harm, especially skeletal, if a woman becomes pregnant after completing a course of biphosphonate therapy. Time between cessation of drug therapy to conception, the particular bisphosphonate used, and route of administration that may cause fetal harm is unknown.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- It is not known if drug is present in breast milk.
- A decision should be made to discontinue breastfeeding or the drug to avoid potential serious adverse reactions in the infant.

## Nursing Considerations

- Be aware that risedronate isn't recommended for patients with severe renal impairment.
- Make sure patient has had a dental checkup before having invasive dental procedures during risedronate therapy, especially if patient has cancer; is receiving angiogenesis inhibitors, chemotherapy, corticosteroids, or head or neck radiation; or has poor oral hygiene because risk of jaw osteonecrosis is increased in these patients.
- Give supplemental calcium and vitamin D, as prescribed, during risedronate therapy if patient's dietary intake is inadequate.

- Give calcium supplements and antacids at different time of day than risedronate administration to avoid impaired drug absorption and altered effectiveness.
- Watch for rare, but possibly severe hypersensitivity reactions such as angioedema, bullous skin reactions, or rash.

## **PATIENT TEACHING**

- Instruct patient to take risedronate at least 1 hour before first food or drink of day (except water) while in an upright position and with 6 to 8 oz of water. Caution against lying down for at least 30 minutes after taking drug to keep it from lodging in esophagus and causing irritation. Also instruct patient not to chew or suck on tablet because doing so may irritate mouth or throat.
- Advise patient to stop taking risedronate and to notify prescriber if she develops dysphagia, new or worsening heartburn, or pain while swallowing, retrosternal pain. Also alert patient that drug may cause severe bone, joint, or muscle pain and to notify prescriber if present occurs.
- Alert patient that drugs in the same class as risedronate have caused severe bone, joint, or muscle pain. If such symptoms appear while taking risedronate, advise patient to contact prescriber.
- Advise patient that if she takes 35 mg once weekly and misses a dose, tell her to take it the morning after she remembers and then to take the next dose on its usual day. If patient takes 75 mg on 2 consecutive days once monthly and she misses both doses with more than 7 days until the next scheduled dose, tell her to take the first missed dose on the morning after she remembers and the second dose the following day. If she misses only 1 of the 2 doses, tell her to take it the morning after she remembers and then resume her normal schedule. If patient takes 150 mg once monthly and misses a dose, urge her to contact prescriber for instructions. Caution patient not to take more than 150 mg within a 7-day period and not to take 2 tablets of any strength on the same day.
- Tell patient to take antacids or calcium supplements at different times than risedronate.
- Urge women of childbearing age to tell prescriber about planned, suspected, or known pregnancy because of risk to fetal skeleton.
- Tell patient to stop risedronate and contact prescriber if allergic reaction occurs. Stress importance of seeking immediate emergency care if she notices swelling or skin abnormalities.

- Instruct patient about proper oral hygiene and about the need to notify prescriber about invasive dental procedures.
- Instruct patient to notify prescriber immediately of any new groin or thigh pain that might be reflective of an atypical femur fracture.

## risperidone

### Perseris, Risperdal, Risperdal Consta, Risperdal M-TAB

## Class and Category

*Pharmacologic class:* Benzisoxazole derivative

*Therapeutic class:* Antipsychotic

## Indications and Dosages

➤ *To treat schizophrenia*

### ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS

**Adults.***Initial:* 2 mg once daily or divided and given as 1 mg twice daily, increased at intervals of 24 hr or longer in increments of 1 to 2 mg daily to recommended dose of 4 to 8 mg daily.

*Maximum:* 16 mg daily.

**Adolescents ages 13 to 17.***Initial:* 0.5 mg once daily, increased as needed every 24 hr or longer in 0.5- to 1-mg increments to target dose of 3 mg daily. *Effective dose range:* 1 to 6 mg once daily. *Maximum:* 6 mg once daily.

## **I.M. INJECTION (RISPERDAL CONSTA)**

**Adults.** *Initial:* After tolerability established with oral risperidone, 25 mg every 2 wk, increased as needed every 4 wk to 37.5 or 50 mg.

*Maximum:* 50 mg every 2 wk.

## **subcutaneous injection (perseris)**

**Adults.** 90 mg or 120 mg once monthly injected into abdomen only.

- *To treat bipolar mania as monotherapy or as adjunct to lithium or valproate therapy*

## **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Adults.** *Initial:* 2 or 3 mg daily, increased as needed by 1 mg daily or longer up to 6 mg. *Maximum:* 6 mg daily for no more than 3 wk.

**Children and adolescents ages 10 to 17.** *Initial:* 0.5 mg once daily, increased as needed every 24 hr or longer in 0.5- to 1-mg increments to recommended dose of 1 to 2.5 mg daily. *Maximum:* 2.5 mg once daily.

## **I.M. INJECTION (RISPERDAL CONSTA)**

**Adults.** After tolerability established with oral risperidone, 25 mg every 2 wk, increased, as needed to 37.5 or 50 mg.

*Maximum:* 50 mg every 2 wk.

- *To treat irritability associated with autistic disorder*

## **ORAL SOLUTION, ORALLY DISINTEGRATING TABLETS, TABLETS**

**Children age 5 and over and adolescents weighing less than 20 kg (44 lb).** *Initial:* 0.25 mg daily, increased

after 4 days to 0.5 mg daily. Dosage further increased, as needed in 2-wk intervals in 0.25 mg increments.

**Children age 5 and over and adolescents weighing 20 kg or more.** *Initial:* 0.5 mg daily, increased after 4 days to 1 mg daily. Dosage further increased, as needed in 2 wk intervals in 0.5 mg increments.

***DOSAGE ADJUSTMENT*** For elderly patients and patients with severe hepatic or renal impairment or who are taking CYP2D6 inhibitors, starting doses reduced to 0.5 mg twice daily, increased in increments of 0.5 mg or less twice daily. For doses above 1.5 mg twice daily, dosage increased in intervals of one week or greater. For patients taking CYP3A4 inducers such as carbamazepine, phenobarbital, phenytoin, or rifampin, dosage may have to be increased up to double the patient's usual dose.

## Mechanism of Action

Selectively blocks serotonin and dopamine receptors in the mesocortical tract of the CNS to suppress psychotic symptoms.

## Incompatibilities

Don't mix oral solution with cola or tea.

## Contraindications

Hypersensitivity to risperidone, paliperidone, or its components

## Interactions

### DRUGS

*antihypertensives*: Increased antihypertensive effects  
*carbamazepine, phenobarbital, phenytoin, rifampin*:  
Increased risperidone clearance with decreased effectiveness  
*clozapine*: Decreased risperidone clearance with long-term concurrent use  
*CNS depressants*: Additive CNS depression  
*fluoxetine, paroxetine*: Increased plasma risperidone level  
*dopamine agonists, levodopa*: Possibly antagonized effects of these drugs

## ACTIVITIES

*alcohol use*: Additive CNS depression

## Adverse Reactions

**CNS**: Abnormal coordination, aggressiveness, agitation, akathisia, anxiety, asthenia, confusion, decreased concentration, depression, dizziness, dream disturbances, drooling, drowsiness, dyskinesia, dystonia, fatigue, fever, headache, **hypothermia**, insomnia, lassitude, malaise, mania, memory loss, nervousness, **neuroleptic malignant syndrome**, paresthesia, Parkinsonism, restlessness, **seizures**, shaking of head repeatedly, sleepwalking, somnambulism, somnolence, tardive dyskinesia, tremor, vertigo

**CV**: **Atrial fibrillation**, **bradycardia**, bundle branch block, **cardiopulmonary arrest**, chest pain, elevated triglyceride levels, first-degree AV block, hypercholesterolemia, orthostatic hypotension, palpitations, **QT-interval prolongation**, tachycardia

**EENT**: Conjunctivitis, decreased or increased salivation, dry mouth, ear pain, epistaxis, nasal congestion,

pharyngitis, retinal artery occlusion, rhinitis, sinusitis, taste alteration, vision changes

**ENDO:** **Diabetic ketoacidosis** (patients with diabetes), elevated prolactin level, galactorrhea, hyperglycemia, hyperprolactinemia, **hypoglycemia**, inappropriate antidiuretic hormone secretion (SIADH), pituitary adenoma, precocious puberty, water intoxication

**GI:** Abdominal pain, anorexia, constipation, diarrhea, gastritis, ileus, indigestion, **intestinal obstruction**, jaundice, nausea, **pancreatitis**, vomiting

**GU:** Amenorrhea, decreased libido, delayed ejaculation, dysmenorrhea, dysuria, glucosuria, hypermenorrhea, incontinence, increased appetite, polyuria, priapism, sexual dysfunction, urinary incontinence or retention, UTI

**HEME:** **Agranulocytosis**, anemia, **leukopenia**, **neutropenia**, **thrombocytopenia**, **thrombotic thrombocytopenic purpura**

**MS:** Arthralgia; back, buttock, or neck pain; dysarthria; muscle weakness; myalgia

**RESP:** Cough, dyspnea, **pulmonary embolism**, **sleep apnea**, upper respiratory tract infection

**SKIN:** Alopecia, diaphoresis, dry skin, eczema, hyperpigmentation, photosensitivity, pruritus, rash, seborrhea

**Other:** **Anaphylaxis**; **angioedema**; flu-like symptoms; infections; injection-site induration, pain, redness, or swelling; weight gain or loss

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-866-961-2388 or <http://womensmentalhealth.org/clinical-and-research-programs/pregnancyregistry/>.

- Drug may cause fetal harm.
- Neonates exposed to drug during the third trimester of pregnancy are at risk for extrapyramidal and withdrawal symptoms.

## LACTATION

- Drug is present in human milk.
- Patient should check with prescriber before breastfeeding.
- If breastfeeding occurs, mother should monitor infant for signs of abnormal muscle movements, excess sedation, failure to thrive, jitteriness, and tremors.

## Nursing Considerations

- Use risperidone cautiously in debilitated patients, elderly patients, and patients with hepatic or renal dysfunction or hypotension because of their increased sensitivity to the drug. Also use risperidone cautiously in patients with a history of seizures; although rare, seizures may occur in those with schizophrenia.

**WARNING** Be aware that risperidone should not be used to treat elderly patients with dementia-related psychosis because it increases risk of death in these patients.

- Be aware that oral risperidone or another antipsychotic should be continued for 3 weeks after long-acting I.M. form of risperidone is first administered to provide an adequate therapeutic plasma level until risperidone release from injection site has begun. If the patient has never received oral risperidone, an oral trial should be prescribed before use of I.M. or subcutaneous forms to determine patient's tolerance of the drug.
- Know that patients with hepatic or renal impairment prescribed the long-acting subcutaneous form of risperidone will need to be carefully titrated up to at least 3 mg daily of oral risperidone. If patient can tolerate the oral dose and is psychiatrically stable, the long-acting subcutaneous form may be initiated at the lower dose of 90 mg once a month.
- Remove I.M. form (Risperdal Consta) from refrigerator and allow it to come to room temperature for at least 30 min before reconstitution.

Follow manufacturer's guidelines for reconstitution, following the illustrations closely and, using only the diluent supplied in the dose pack.

- Give I.M. form using only the needle supplied in the dose pack. Inject entire contents of syringe into the upper outer quadrant of gluteal area using the 2-inch needle or into the deltoid muscle using the 1-inch needle within 2 minutes of reconstitution. Never combine the two different dose strengths for I.M. injection into a single administration. If drug can't be given right after reconstitution, shake the upright vial vigorously back and forth until particles are resuspended. Discard reconstituted drug if not used within 6 hours. Never administer I.M. form intravenously.
- Remove subcutaneous package (Perseris) from refrigerator and allow it to come to room temperature for at least 15 minutes before preparing drug for administration. Only prepare drug when ready to administer the dose, not before.
- To prepare a subcutaneous dose (Perseris), first hold the powder syringe in upright position and tap the barrel of the syringe to dislodge the packed powder. Then remove the cap first from the liquid syringe and then from the powder syringe. Place the liquid syringe on top of the powder syringe and connect the two syringes by twisting approximately 3/4 turn. Do not overtighten. Keep fingers off the plungers to avoid spillage of drug. Failure to fully mix drug can result in incorrect dosage. Transfer the contents of the liquid syringe into the powder syringe. Gently push the powder syringe plunger until resistance is felt. Repeat this gentle back-and-forth process for 5 cycles. Continue mixing the syringes for an additional 55 cycles. When fully mixed, drug should be a cloudy suspension that is uniform in color. It can vary from white to yellow-green. If any clear areas occur in the mixture, continue to mix it until the distribution of the color is uniform. Then transfer all the contents into the liquid syringe. After this, while maintaining slight pressure on the powder syringe plunger, pull back gently on the liquid syringe plunger while twisting the syringes apart. Finally, attach the safety needle by twisting until finger-tight.
- Administer subcutaneous form (Perseris) into the abdomen only after removing excess air from syringe; inject drug slowly and steadily. Do not rub the injection site after the injection. If there is bleeding, apply a bandage but use minimal pressure.
- Monitor for orthostatic hypotension, especially in patients with cardiac or cerebrovascular disease.

**WARNING** Immediately notify prescriber and expect to stop giving risperidone if patient shows evidence of neuroleptic malignant syndrome (altered mental status,

autonomic instability, hyperpyrexia, muscle rigidity), which can be fatal.

- Monitor patient's blood glucose and lipid levels as ordered because drug increases the risk of hyperglycemia and hypercholesterolemia.
- Monitor patient's CBC, as ordered, because serious adverse hematologic reactions may occur, such as agranulocytosis, leukopenia, or neutropenia. More frequent monitoring during the first few months of risperidone therapy is recommended for patients with a history of drug-induced leukopenia or neutropenia, or those who have had a significantly low WBC count in the past. If abnormalities occur during therapy, monitor patient for fever or other signs of infection, notify prescriber, and expect drug to be discontinued if severe.
- Institute fall precautions.

## **PATIENT TEACHING**

- Instruct patient to dilute risperidone oral solution with water, coffee, orange juice, or low-fat milk, but not with cola or tea.
- Tell patient prescribed orally disintegrating tablets to break open the blister unit with dry hands by peeling the foil back to expose the tablet. Emphasize the importance of not pushing tablet through the foil because this could damage the tablet. Once patient has removed tablet, she should place immediately on her tongue, where it will dissolve within seconds. Tell patient not to chew orally disintegrating tablet or attempt to spit it out of her mouth.
- Urge patient to avoid alcohol because of its additive CNS effects.
- Caution diabetic patient to monitor blood glucose level closely, because risperidone may increase it.
- Caution patient that risperidone may cause sleepwalking
- Caution patient to avoid performing hazardous activities such as driving until CNS effects are known and subside. Review fall precautions with patient.
- Instruct mothers who are breastfeeding while taking risperidone to monitor the infant for abnormal muscle movements, excess sedation, failure to thrive, jitteriness, or tremors.
- Inform women of childbearing age that risperidone may reduce fertility, but that this is reversible after drug is discontinued.

# rituximab

**Rituxan**

## Class and Category

*Pharmacologic class:* Monoclonal antibody

*Therapeutic class:* Anti-inflammatory, immunosuppressant

## Indications and Dosages

➤ *To treat rheumatoid arthritis*

### I.V. INFUSION

**Adults.** Two 1,000-mg infusions separated by 2 wk. Subsequent courses administered every 24 wk or based on clinical evaluation, but no sooner than every 16 wk. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min, to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr; if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

➤ *To treat moderate to severe pemphigus*

### I.V. INFUSION

**Adults.** *Induction:* Two 1,000-mg infusions separated by 2 wk. *Maintenance:* 500-mg infusion at month 12 and every 6 months thereafter or based on clinical evaluation. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30

min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr; if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**Adults who have relapsed.** 1,000-mg infusion on relapse. See manufacturer guidelines for infusion rate. Subsequent infusions given no sooner than 16 wk following previous infusion.

➤ *To treat non-Hodgkin's lymphoma (NHL)*

## **I.V. INFUSION**

**Adults with relapsed or who have refractory, low-grade, or follicular CD20-positive, B-cell NHL.** 375 mg/m<sup>2</sup> once a wk for 4 to 8 doses. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr; if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**Adults receiving retreatment for relapsed or refractory, low-grade, or follicular CD20-positive, B-cell NHL.** 375 mg/m<sup>2</sup> once a wk for 4 doses. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr, and if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**Adults with previously untreated follicular, CD20-positive, B-cell NHL.** 375 mg/m<sup>2</sup> administered on day 1 of each cycle of chemotherapy for up to 8 doses.

*Maintenance:* If complete or partial response occurs after chemotherapy, 375 mg/m<sup>2</sup> every 8 wk for 12 doses. Follow

manufacturer guidelines for initial infusion rate and subsequent infusion rates.

**Adults with nonprogressing, low-grade, CD20-positive, B-cell NHL after first-line CVP**

**chemotherapy.** Following completion of 6 to 8 cycles of CVP chemotherapy, 375 mg/m<sup>2</sup> once weekly for 4 doses at 6-month intervals for a maximum of 16 doses. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr, and if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**Adults with diffuse large B-cell NHL.** 375 mg/m<sup>2</sup> on day 1 of each cycle of chemotherapy for up to 8 infusions. Follow manufacturer guidelines for initial infusion rate and subsequent infusion rates.

➤ *To treat chronic lymphocytic leukemia (CLL)*

## **I.V. INFUSION**

**Adults.** 375 mg/m<sup>2</sup> on day prior to initiation of FC chemotherapy, then 500 mg/m<sup>2</sup> on day 1 of cycles 2- 6 (every 28 days). Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr, and if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

➤ *To treat granulomatosis with polyangiitis (Wegener's granulomatosis) and microscopic polyangiitis*

## **I.V. INFUSION**

**Adults.** *Induction:* 375 mg/m<sup>2</sup> once a wk for 4 wk.

*Maintenance:* Two 500-mg infusions separated by 2 wk, followed by a 500-mg infusion every 6 months based on clinical evaluation. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr and if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**Children.** *Induction:* 375 mg/m<sup>2</sup> once a wk for 4 wk.

*Maintenance:* Two 250-mg/m<sup>2</sup> infusions separated by 2 wk, followed by a 250-mg/m<sup>2</sup> infusion every 6 months based on clinical evaluation. Infuse first infusion at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr, and if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**DOSAGE ADJUSTMENT** Follow manufacturer guidelines for each indication and the additional drugs given concomitantly that may have to be adjusted with rituximab therapy.

## Mechanism of Action

Targets the CD20 antigen expressed on the surface of pre-B and mature B lymphocytes. Upon binding to CD20, drug-mediated B-cell lysis occurs. B cells are also believed to play a role in the pathogenesis of rheumatoid arthritis and associated chronic synovitis. In rheumatoid arthritis, B cells may be acting at multiple sites in the autoimmune/inflammatory process, including through production of rheumatoid factor and other auto-antibodies, antigen presentation, T-cell activation, and/or

proinflammatory cytokine production. Improvement of rheumatoid arthritis signs and symptoms may occur when B-cell lysis occurs.

## Incompatibilities

Do not mix or dilute rituximab with any other solution except for 0.9% sodium chloride or 5% dextrose injection, and do not mix with any other drugs.

## Contraindications

Hypersensitivity to rituximab or its components

## Interactions

### DRUGS

*immunosuppressants*: enhanced immunosuppressive effects  
*vaccines (live)*: possibly increased risk of infection

## Adverse Reactions

**CNS:** Anxiety, asthenia, chills, depression, dizziness, fatigue, fever, headache, insomnia, irritability, migraine, paresthesia, peripheral sensory neuropathy, progressive multifocal leukoencephalopathy (PML), posterior reversible encephalopathy syndrome, reversible posterior leukoencephalopathy syndrome

**CV:** **Cardiogenic shock, fatal cardiac failure**, hypertension, **hypotension**, increased LDH, **MI**, peripheral edema, systemic vasculitis, tachycardia, **ventricular fibrillation**

**EENT:** **Conjunctivitis, epistaxis, optic neuritis, rhinitis**, sinusitis, throat irritation, uveitis

**ENDO:** Hyperglycemia, hypophosphatemia, weight gain

**GI:** Abdominal pain, **bowel obstruction and perforation**, diarrhea, dyspepsia, elevated liver enzymes, nausea, vomiting

**GU:** UTI

**HEME:** **Anemia, bone marrow hypoplasia, hyperviscosity syndrome in Waldenstrom's macroglobulinemia, leukopenia, lymphopenia, neutropenia, prolonged hypogammaglobulinemia, prolonged pancytopenia, thrombocytopenia**

**MS:** Arthralgia, back pain, muscle spasms, musculoskeletal pain, myalgia, polyarticular arthritis

**RESP:** **Bronchospasm**, dyspnea, **fatal bronchiolitis obliterans and interstitial lung disease**, increased cough, pleuritis, upper respiratory infections

**SKIN:** Flushing, lichenoid or vesiculobullous dermatitis, night sweats, **paraneoplastic pemphigus (blistering of mucous membranes and skin)**, pruritus, pyoderma gangrenosum (large, painful sores), rash, skin papilloma, **Stevens-Johnson syndrome, toxic epidermal necrolysis**, urticaria

**Other:** **Angioedema**, antibody formation to rituximab, **disease progression of Kaposi's sarcoma**, febrile neutropenia, generalized pain, herpes simplex or zoster, **HIV-associated lymphoma (fatal)**, infections (bacterial, fungal, viral), infusion reactions (**angioedema, bronchospasm**, chills/rigors, dizziness, fever, headache, myalgia, nausea, pruritus, rash, urticaria, vomiting), lupus-like syndrome, serum sickness, **tumor lysis (acute renal failure, hyperkalemia, hyperphosphatemia, hyperuricemia, hypocalcemia)**, vasculitis with rash

## **Childbearing Considerations**

## **PREGNANCY**

- Drug can cause fetal harm such as B-cell lymphocytopenia.
- Use with caution only if benefit to mother outweighs potential risk to fetus.
- If drug used during pregnancy, neonate should be observed for signs of infection.

## **LACTATION**

- It is not known if drug is present in breast milk.
- Breastfeeding is not recommended during drug therapy and for 6 months following last dose.

## **REPRODUCTION**

- Advise women of childbearing age to use effective contraception during drug treatment and for at least 12 months after last dose.

## **Nursing Considerations**

- Screen all patients for HBV by measuring HBsAg and anti-HBc before initiating rituximab, as ordered, because HBV reactivation can occur and can result in severe liver dysfunction or even death. Patient will need to be monitored for up to 24 months after completion of rituximab therapy. Also obtain complete blood count (CBC), including platelets, prior to first dose. Once treatment is begun, obtain CBC with differential and platelet counts prior to each drug course in patients with lymphoid malignancies. During treatment with chemotherapy, obtain CBC with differential and platelet counts at weekly to monthly intervals and more frequently in patients who develop cytopenias.
- Ensure that patient is up to date on immunizations before rituximab is begun because immunization with live-virus vaccines is not recommended before or during rituximab therapy. Nonlive vaccines should be administered at least 4 weeks before a course of rituximab is given.
- Premedicate patient with acetaminophen and an antihistamine prior to each infusion, as ordered, to prevent or lessen degree of severity of an

infusion reaction. If glucocorticoid therapy is part of patient's regimen, it should also be administered about 30 min prior to infusion, as ordered.

- Prepare infusion by withdrawing the necessary amount of rituximab and dilute to a final concentration of 1 mg/ml to 4 mg/ml in an infusion containing either 0.9% sodium chloride or 5% dextrose injection. Gently invert bag to mix the solution. Do not mix or dilute with other drugs. Discard any unused portion left in vial. Diluted solutions may be stored refrigerated for 24 hours.
- Infuse first infusion for patients not treated for certain types of non-Hodgkins lymphoma at 50 mg/hr. If no infusion toxicity noted, infusion rate increased by 50-mg/hr increments every 30 min to a maximum of 400 mg/hr. For subsequent infusions, initiate infusion rate at 100 mg/hr, and if no infusion toxicity noted, rate increased by 100-mg/hr increments at 30-min intervals to a maximum of 400 mg/hr.

**WARNING** Be aware that most infusion reactions occur within 30 to 120 minutes of beginning the first infusion.

Patients at higher risk include patients with preexisting cardiac or pulmonary conditions, those who experienced prior cardiopulmonary adverse reactions, and those with high numbers of circulating malignant cells (25,000 mm<sup>3</sup> or greater). Stop infusion or slow infusion rate for infusion-related reactions, some of which could be life-threatening, such as angioedema, bronchospasms, and hypotension. Know that reaction may resolve with slowing or interruption of the infusion and with supportive care (acetaminophen, diphenhydramine, and intravenous saline). Expect to resume infusion upon improvement of symptoms by continuing infusion at one-half the previous rate.

- Be prepared to perform cardiac monitoring during and after all infusions of rituximab for patients who develop clinically significant arrhythmias or who have a history of angina or arrhythmia. This is because life-threatening cardiac adverse reactions, such as cardiogenic shock, MI, or ventricular fibrillation, may occur with rituximab therapy.

**WARNING** Monitor patient being treated for non-Hodgkin's lymphoma for tumor lysis syndrome (acute renal

failure, hyperkalemia, hyperphosphatemia, and hypocalcemia), which can sometimes be fatal and usually occurs within 12 to 24 hours after the first infusion. Patients at higher risk include patients with high number of circulating malignant cells (25,000/mm<sub>3</sub> or greater) or high tumor burden. If present, expect to provide aggressive intravenous hydration and antihyperuricemic therapy in patients at high risk, as ordered. Expect electrolyte abnormalities to be corrected and renal function and fluid balance monitored, as ordered. Also, provide supportive care that may include dialysis, as ordered.

- Know that prophylaxis treatment for *Pneumocystis jirovecii* pneumonia and herpes virus infections may be given during treatment with rituximab and in some cases up to 6 or 12 months following last infusion.
- Obtain CBC with differential and platelet counts at 2- to 4-month intervals for patients with granulomatosis with polyangiitis, microscopic polyangiitis, and rheumatoid arthritis. Continue to monitor all patients throughout rituximab therapy for cytopenias and after final dose and until resolution, if present.

**WARNING** Monitor patient for severe mucocutaneous reactions. If present, notify prescriber and expect drug to be discontinued.

**WARNING** Monitor patient for new-onset neurological manifestations that may be suggestive of progressive multifocal leukoencephalopathy (PML), which can occur with rituximab therapy. Know that most cases are diagnosed within 12 months of the last infusion of drug. If suspected, expect an MRI and lumbar puncture to be obtained. If confirmed, expect rituximab to be discontinued.

- Institute infection control measures and monitor patient for signs and symptoms of infection, as serious infections, including fatal bacterial, fungal, and new or reactivated viral infections, can occur. If infection is

serious, expect rituximab to be discontinued and appropriate anti-infective therapy instituted.

- Monitor patient's serum creatinine level and patient for oliguria if being treated for NHL with rituximab because renal toxicity may occur. Renal toxicity may occur with tumor lysis syndrome but also in patients receiving cisplatin. Be aware that concomitant administration of cisplatin and rituximab is not an approved treatment regimen. In addition, patient treated for NHL is also at risk for bowel obstruction and perforation. If patient develops abdominal pain or repeated vomiting, notify prescriber at once.

## PATIENT TEACHING

**WARNING** Instruct patient on the signs and symptoms of an infusion reaction. Urge patient to contact prescriber immediately if present.

- Tell patient to monitor the skin for abnormal effects. If blisters, painful sores, or ulcers appear in the mouth, or if pustules, peeling skin, or rash develops, tell patient to contact prescriber immediately.
- Review other signs and symptoms that should be reported to prescriber, including prolonged, severe, or unusual reactions that may warrant immediate attention, such as those that may occur with the cardiovascular system, hepatitis B virus reaction, progressive multifocal leukoencephalopathy, and tumor lysis syndrome.
- Instruct patient on infection control measures, including avoiding people who are ill.

**WARNING** Advise women of childbearing age to use effective contraception while receiving rituximab and for 12 months after last dose.

- Instruct women not to breastfeed during treatment with rituximab and for at least 6 months after last dose.

**ritonavir**

# Norvir

## Class and Category

*Pharmacologic class:* Protease inhibitor

*Therapeutic class:* Antiretroviral

## Indications and Dosages

- *As adjunct to treat human immunodeficiency viral type 1 (HIV-1) infection*

### TABLETS

**Adults.** *Initial:* 300 mg twice daily with meals, increased by 100 mg twice daily every 2 to 3 days until maximum dose reached. *Maximum:* 600 mg twice daily.

**Children older than 1 month and able to swallow tablets.** *Initial:* 250 mg/m<sup>2</sup> twice daily with meals, increased by 50 mg/m<sup>2</sup> twice daily every 2 to 3 days until a maintenance dosage is reached. *Maintenance:* 350 to 400 mg/m<sup>2</sup> twice daily with meals. *Maximum:* 600 mg twice daily.

### ORAL POWDER OR SOLUTION

**Adults.** *Initial:* 300 mg twice daily with meals, increased by 100 mg twice daily every 2 to 3 days until maximum dose is reached. *Maximum:* 600 mg twice daily.

**Infants at least 44 weeks old (calculated from first day of mother's last menstrual period to birth plus the time elapsed after birth) and children.** *Initial:* 250 mg/m<sup>2</sup> twice daily with meals, increased by 50 mg/m<sup>2</sup>

twice daily every 2 to 3 days until a maintenance dosage is reached.

*Maintenance:* 350 to 400 mg/m<sup>2</sup> twice daily with meals.

*Maximum:* 600 mg twice daily.

**DOSAGE ADJUSTMENT** For patient taking other protease inhibitors such as atazanavir, darunavir, fosamprenavir, saquinavir, and tipranavir, dosage reduced. Oral powder should not be used for dosing increments less than 100 mg or for incremental doses between 100 mg intervals; oral solution should be used in these situations instead.

## Mechanism of Action

Inhibits HIV protease to render the enzyme incapable of processing the Gag-Pol polyprotein precursor, which leads to the production of noninfectious immature HIV particles.

## Contraindications

Concomitant therapy with other protease inhibitors, potent CYP3A inducers, or therapy that is highly dependent on CYP3A for drug clearance and for which elevated plasma concentrations have resulted in serious and/or life-threatening reactions (alfuzosin, amiodarone, cisapride, colchicine, dihydroergotamine, dronedarone, ergotamine, flecainide, lomitapide, lovastatin, lurasidone, methylergonovine, midazolam [oral], pimozide, propafenone, quinidine, ranolazine, St. John's wort, sildenafil [when used for treatment of pulmonary arterial hypertension], simvastatin, triazolam, voriconazole); hypersensitivity to ritonavir or its components; use of potent CYP3A inducers where significantly reduced ritonavir plasma concentrations may be associated with the potential loss of virologic response and possible resistance

and cross-resistance such as anticancer agents (apalutamide) or herbal products (St. John's Wort)

## Interactions

### DRUGS

*amprenavir, atazanavir, atorvastatin, bedaquiline, bosentan, buspirone, carbamazepine, clarithromycin, clonazepam, clorazepate, colchicine, corticosteroids, cyclosporine, darunavir, dasatinib, desipramine, diazepam, diltiazem, disopyramide, dronabinol, estazolam, ethinyl estradiol, ethosuximide, fentanyl, fluoxetine, flurazepam, ibrutinib, indinavir, itraconazole, ketoconazole, lidocaine, lomitapide, maraviroc, methamphetamine, metoprolol, mexiletine, midazolam (parenteral), nefazodone, nifedipine, nilotinib, paroxetine, perphenazine, propoxyphene, quetiapine, quinine, rifabutin, risperidone, rosuvastatin, salmeterol, saquinavir, simeprevir, sirolimus, tacrolimus, thioridazine, timolol, tipranavir, trazodone, tricyclic antidepressants, venetoclax, verapamil, zolpidem:* Increased concentration of these drugs with possible risk of prolonged action and adverse reactions

*atovaquone, bupropion, divalproex, lamotrigine, phenytoin, raltegravir, rifampin, theophylline, voriconazole:* Decreased concentration of these drugs with possible decreased efficacy

*avanafil, sildenafil, tadalafil, vardenafil:* Increased concentration of PDE5 inhibitors with possible increased risk of adverse reactions, including hypotension, prolonged erection, syncope, visual changes

*delavirdine:* Increased concentration of ritonavir with possible risk of prolonged action and adverse reactions

*digoxin:* Increased concentration of digoxin with possible increased risk of digitalis toxicity

*disulfiram, metronidazole*: Increased risk of adverse reactions, especially “hangover” symptoms, because ritonavir contains ethanol

*methadone*: Decreased concentration of methadone with increased risk of opiate withdrawal symptoms

*meperidine*: Increased concentrations of the metabolite of meperidine with possible risk of prolonged action and adverse reactions

*rivaroxaban*: Increased concentration of rivaroxaban with possible increased risk of bleeding

*vinblastine, vincristine*: Increased concentration of these drugs with increased risk of significant gastrointestinal or hematologic adverse reactions

*warfarin*: Altered INR in either direction requiring possible dosage adjustments

## Adverse Reactions

**CNS**: Asthenia, attention disturbance, confusion, dizziness, fatigue, paresthesia, peripheral neuropathy, **seizures**, syncope

**CV**: **AV block**, elevated cholesterol and triglycerides, hypertension, **hypotension**, orthostatic hypotension, peripheral edema, right bundle branch block

**EENT**: Blurred vision, oral paresthesia, oropharyngeal pain

**ENDO**: Cushingoid appearance, fat redistribution, hot flashes

**GI**: Abdominal pain, bilirubin increase, diarrhea, dysgeusia, dyspepsia, elevated liver and pancreatic enzymes, flatulence, gastroesophageal reflux disease, **GI hemorrhage, hepatitis, hepatotoxicity**, jaundice, nausea, **pancreatitis**, vomiting

**GU**: Increased urination, **renal insufficiency**

**HEME**: Anemia, decreased red blood cells, **leukopenia, neutropenia, thrombocytopenia**

**MS:** Arthralgia, back pain, elevated creatine phosphokinase, myalgia, myopathy, peripheral coldness

**RESP:** **Bronchospasm**, coughing

**SKIN:** Acne, facial edema, flushing, pruritus, rash, skin eruptions, **Stevens-Johnson syndrome**, **toxic epidermal necrolysis**, urticaria

**Other:** **Anaphylaxis**, **angioedema**, dehydration, **electrolyte imbalances**, gout, immune reconstitution syndrome, lipodystrophy (acquired)

## Childbearing Considerations

### PREGNANCY

- Pregnancy exposure registry: 1-800-258-4263.
- It is not known if drug can cause fetal harm.
- Be aware that the oral solution form is not recommended during pregnancy because there is no known safe level of ethanol exposure during pregnancy.
- Use with caution only if benefit to mother outweighs potential risk to fetus.

### LACTATION

- Drug is present in breast milk.
- The Centers for Disease Control and Prevention recommends that HIV-1 infected mothers not breastfeed to avoid risking postnatal transmission of HIV-1 infection to infants. They also do not recommend breastfeeding because of potential drug-induced adverse reactions in the infant.

## Nursing Considerations

- Use cautiously in patients with cardiomyopathies, ischemic heart disease, preexisting conduction system abnormalities, or structural heart disease, because ritonavir may prolong patient's PR interval.

- Use cautiously in patients with hepatitis (especially B and C), liver enzyme abnormalities, or preexisting liver disease, because of the increased risk of hepatotoxicity during ritonavir therapy. Expect to monitor liver enzymes, as ordered, in these patients more frequently during the first 3 months of ritonavir therapy.
- Expect to check patient's cholesterol and triglyceride levels prior to starting ritonavir therapy and then periodically throughout therapy. Notify prescriber if elevated, and expect patient to be treated for the lipid disorder.
- Be aware that oral powder form of ritonavir should only be used for dosing increments of 100 mg. If the dose is less than 100 mg or the dose falls between 100-mg intervals, other forms should be used instead of the powder.
- Administer ritonavir with meals. Mix oral solution with Advera, chocolate milk, or Ensure within 1 hour of administration to help improve the taste.
- Mix oral powder form with soft food such as applesauce or vanilla pudding or mix with liquids such as chocolate milk, infant formula, or water and use a calibrated dosing syringe to measure dosage, especially for infants and children. Once mixed, use within 2 hours or discard.
- Know that the oral powder form may be given via a feeding tube after being mixed with water.
- Do not use oral solution for use with polyurethane feeding tubes, because the presence of ethanol in the solution may be incompatible. Also know that oral solution should not be given to pregnant women because of the ethanol content. Be aware that the total amounts of ethanol and propylene glycol from all drugs given to infants 1 to 6 months of age should be taken into account to avoid toxicity.
- Be aware that a patient who takes 600-mg twice daily soft-gel capsule dose may experience more gastrointestinal adverse reactions (such as abdominal pain, diarrhea, nausea, and vomiting) when switching from the soft gel capsule to the tablet form, because of greater maximum plasma concentration in the tablet compared to the soft gel capsule. Know that these adverse events may diminish as ritonavir therapy continues.
- Know that dihydroergotamine or ergotamine should not be coadministered with ritonavir because acute ergot toxicity may occur, exhibited by ischemia of the extremities and other tissues including the central nervous system and vasospasm.
- Be aware that adrenal suppression and Cushing's syndrome may occur when ritonavir is coadministered with budesonide or fluticasone propionate.

**WARNING** Assess patient's skin regularly for signs of a hypersensitivity reaction. Know that angioedema, mild skin eruptions, and urticaria have occurred with ritonavir therapy. Cases of anaphylaxis, Stevens-Johnson syndrome, and toxic epidermal necrolysis have also occurred with ritonavir therapy. Report any abnormal findings and expect ritonavir to be discontinued if reaction is severe.

- Monitor patient's liver enzymes, as ordered, and patient for signs and symptoms of liver dysfunction.
- Monitor patient for pancreatitis such as the presence of abdominal pain, abnormal serum amylase or lipase values, nausea, or vomiting. If suspected, notify prescriber and expect ritonavir to be discontinued if confirmed.
- Monitor patient's blood glucose levels throughout ritonavir therapy, because some patients have experienced an exacerbation of diabetes mellitus or have developed hyperglycemia or new-onset diabetes mellitus with protease inhibitor therapy.
